On his *admission*, urine was found to be largely extravasated in the perinæum, scrotum, and prepuce, extending considerably above the pubes, more especially on the left side. His health did not appear as much disturbed as might have been expected from the extent of the effusion. (In fact, he had walked to the hospital, and for some time stoutly resisted all the arguments urged to induce him to become an in-patient.) He could give no precise information as to when he last emptied his bladder, which was now observed a good deal distended in the usual situation. His tongue was slightly furred, but moist; and his pulse 85, small, and weak. Free incisions were made in the perinæum, scrotum, prepuce, and above the pubes towards the left side. That in the perinæum was followed by a gush of fetid, urinous, purulent fluid, which gave considerable relief. Fomentations were ordered to the parts. To take a tablespoonful of brandy every hour, with eight drops of laudanum; wine, beef-tea, and arrowroot.

31. During the night a large quantity of urine has been discharged through the incision in the perinæum, soaking through a quadrupled sheet in less than an hour, and notwithstanding frequent changes of the drawsheets, saturating the mattrass, and forming a large pool on the floor. He slept for several hours at different times, and has taken a good deal of nourishment during the night; tongue much the same as yesterday, if anything, rather more dry; pulse, 90, small, and weak. Considerable tenderness over the abdomen, which is a little tympanitic; bowels have not acted since his admission. ℞ Spt ammon. aromat. ʒj, Magnes. ustæ, ʒj, Aq. menth. pip. ℥iv. ft. mist. capt dim. statim et rep., post. hor duas. To continue the beef-tea and arrowroot, with wine and brandy, when necessary. A bag filled with dry heated camomile flowers to be applied over his abdomen, and changed frequently. Evening: Somewhat better; less tenderness of abdomen; tympanitis has almost entirely disappeared; pulse fuller and firmer; tongue rather dry and furred. He has passed a large quantity of urine during the day. The extent of the effusion has certainly not increased, and above the pubes a red line of healthy inflammation appears.

June 1. Bowels have not been yet relieved. To have an enema of gruel and soap. Urine still discharges freely; abdomen a little tender; takes beef-tea with much relish. Pulse 90, fuller; tongue rather dry. Evening: His bowels have been relieved twice by the injection, and he has passed a good deal of flatus with much relief; appetite still good; pulse much the same as in the morning, tongue not so dry; no abdominal tenderness; a free discharge of urine takes place through the perinæum as well as from the incisions above the pubes.

2.—The patient's appearance is altogether more favourable; there is no tenderness over the abdomen nor tympanitis; tongue cleaner and moister; pulse 80, firmer; appetite continues good. There are, however, very large sloughs to separate, and the patient will certainly require great care, and the administration of as much support as possible.

The patient progressed favourably until June 6th, when his bowels were rather relaxed. This soon ceased on his taking a mixture, containing aromatic confection, chalk, and tincture of opium. Sloughs separating favourably; no urine passed by the urethra; appetite good, and he takes a pint of porter daily, with wine, beef-tea, and mutton.

12.—Is going on well; no urine has as yet passed by the urethra. The sloughs have mostly all separated, and a healthy granulating surface appears. The wound in the perinæum is rapidly filling up.

17.—The patient improved in strength. The wounds granulating, dressed with red wash; the urine no longer passes through the perinæum, but is voided by the incisions above the pubes. None has as yet been passed by the urethra. Evening: This evening the patient complains of much pain and tenderness over the abdomen. The pulse is quick and thready; the tongue dry, and covered with a whitish fur. Fifteen leeches, with fomentations to the abdomen, and mercury and chalk to be administered internally combined with opium.

18.—The patient is worse this morning; he has all the symptoms of acute peritonitis. Leeches to the abdomen to be repeated, and followed by fomentations constantly applied.

11 P.M.—Tympanitic state of the abdomen; extremities cold; pulse very rapid, small, and thready; tongue covered by a dry, brown fur. Mustard poultices to the abdomen.

19.—During the night there was constant delirium, and this morning the patient was insensible; and at eleven o'clock he died.

Post-mortem appearances twenty-six hours after death. Body a good deal emaciated; abdomen much distended, and as tense as a drum. The wounds in the perinæum, scrotum, and above the pubes are all apparently healthy, and going on rapidly towards cicatrisation. On opening the abdominal cavity the peritoneum was found covered by opake flakes of lymph, and in the lower parts of the cavity, towards the pelvis, a good deal of opake serum was found. On removing the bladder, it was found to be enormously hypertrophied; its walls being in some places upwards of an inch in thickness. At its fundus, a little to the right of the mesial line, a small abscess was found in the substance of the viscus, which had opened in two situations; one into the cavity of the organ, and the other by a very small opening into the cavity of the peritoneum, thus allowing a free escape for the urine into that cavity, and at once explaining the origin of the peritonitis as well as the utter futility of the attempts to relieve it. On dissecting the perinæum the sloughing consequent on the effusion of urine was found to be confined to the superficial cellular tissue; the urethra was almost closed near its membranous portion by a very narrow stricture (which would hardly admit a bristle), and behind this the canal was ruptured. The ureters of the pelves and kidneys were a good deal dilated.

Needle in the Gall-bladder.—Dr. Tebbetts, of Andover, N. H., has published in the *Boston Medical and Surgical Journal*, the case of a boy, two years of age, who had previously been remarkably healthy, but was attacked with abdominal disease, the exact character of which it is impossible to learn, so imperfectly is the case recorded, but which terminated fatally in about ten days. On examination after death, the stomach and small intestines showed appearances of congestion, with slight inflammation. The spleen, pancreas, kidneys, bladder, and large bowels, appeared perfectly normal. The liver was nearly twice as large as natural, highly congested, and also showed some appearances of inflammation. The gall-bladder was distended to more than twice its original size, with very dark-coloured bile, and contained a common sewing needle, highly polished, about one quarter part of its length (the pointed extremity) being gone. There was no appearance of the needle being corroded, the point merely showing signs of recent fracture. The inside coat of the gall-bladder was completely disorganised, from the inflammation which the needle had produced. The examination of the brain and thoracic organs was not made. When or how the needle got into the gall bladder is altogether unknown.

PROGRESS OF FRENCH SCIENCE.

(FROM OUR OWN CORRESPONDENT.)

Paris, July 13, 1845.

Power of motion of the upper and lower limbs of the left side paralysed; slight contraction of the muscles of the upper extremity; chalky transformation of the arteries of the brain.—The following case, which I owe to the kindness of Dr. Hillairet, occurred in the clinical wards of Professor Bouillaud, who, from the symptoms, diagnosticated *hemorrhage in the right thalamus nervorum opticorum and corpus striatum, as well as in the surrounding parts.* Case.—Susannah Rendilot, ætat. 69, born at Nancy, living in Paris for the last forty-five years, entered the Hospital de la Charité on the 23rd of February, 1844, and was placed in the Salle St. Madelaine, No. 13; of feeble constitution; lymphatico-nervous temperament; catamenia were always regular, but ceased about fifteen years ago; mother of three children; accouchements had taken place without any accident; at 22, was affected with rheumatism of the right arm, which was complicated with little or no fever, and, after two months' treatment, yielded to frictions with a camphorated ammoniacal liniment; with the exception of this disease, had never been ill. The day before her entry, on waking, she found that all power of motion was abolished in the left arm and leg, together with a considerable degree of numbness, and impossibility of moving out of bed. To these symptoms, intense cephalalgia, with slight giddiness when she sat up, and anorexia, were added the day after; neither nausea nor vomiting; sleep natural; no treatment had been prescribed, and she had taken nothing but broth since the disease commenced. No cause could be assigned for the attack.

State on Admission.—Face yellow, without any characteristic morbid expression; mouth considerably deformed, upper lip drawn to the right; tongue remains in its normal situation, and is mobile; speech somewhat difficult; pupils dilated, contracting by the influence of a vivid light; hearing normal; left upper and lower limbs completely paralysed; when raised from the bed, and let go, they fall like an inert mass; sensibility normal; forearm slightly bent on the arm; tongue rose coloured, clean, and moist; thirst; loss of appetite; difficult deglutition. Nothing remarkable in the abdomen; a natural stool was passed yesterday; micturition not so easy as in the normal state; pulse 88, full, regular; matity of the præcordial region does not extend beyond the usual limits; bruits natural, but somewhat harsher than usual; no bellows' sound; percussion and auscultation of the thorax indicated nothing wrong; cephalalgia limited to the upper and central portion of the right side of the head; no dazzling nor giddiness while lying down; *intelligence in its normal state;* no bellows' sound in the carotids.

Venesectio ad ʒx; ordinary tisanne.

24.—Paralysis continues; semi-flexion of the limbs, yielding to the slightest effort; mouth deviates slightly to the right; in the act of blowing, the lips contract as usual; pupils as before; motion of the lids free; pulse 88, regular, full; the clot of blood drawn from the arm very slightly cupped; no buffy coat; normal consistency; serosity somewhat opaline.

℞. Sod. sulphat. ℥j, statim sumend. ex cyath. decoct. herb. (bouillon and herbs, composed of leaves of sorrel, ʒxiij, lettuce, white beet, and chervil, of each ʒv, boiled in water, ℔jss, to which is added butter and salt, of each ʒss); Enema cum ol. oliv. ℥ij. Vespere: two cups of broth.

25.—Cephalalgia no longer exists; good night's rest; speech easier; pulse 88, not so feeble, and softer; limbs and mouth as before.

Repetant. medicam.

26.—Death took place at 5 A.M. without a struggle; her end might be compared to a fire, which goes out for want of fuel.

Autopsy, performed twenty-eight hours after death.—Brain covered with serosity; on removing it, the basillary artery and its divisions were found to be covered with a calcareous secretion; cerebral substance, when cut, offered numerous red spots; examined with the greatest care, no traces of hemorrhage nor any remarkable softening could be found, and it could hardly be said that the right thalamus nervorum opticorum, or corpus striatum, was firmer than its fellow; nothing abnormal in the ventricles, the pons varolii, or the medulla oblongata; all were firm; the only lesion which attracted attention was the *chalky condition of the arteries of the base of the brain.* Medulla spinalis and cerebellum in their normal condition. Heart considerably hypertrophied; the walls of the left ventricle, near its base, thicker than usual; the semilunar valves evidently thickened, cartilaginous, and presenting near their base several chalky spots; except this they were normal; mitral valves opaline and thickened; orifices of natural dimensions; right cavities rather larger than usual; tricuspid valves of an opaline tint, and a slight tumefaction on their free edges. Lungs slightly engorged. Spleen somewhat softened. Nothing remarkable in the other organs.

Remarks.—A microscopist having examined the cerebral substance with the microscope, the result of his investigations may here be given, although they do not explain why the paralysis affected one side only. "In the right corpus striatum and thalamus nervorum opticorum, a part of the cerebral substance was softened. The microscopical examination of this part shewed that the varicose tubes of the brain were broken, and that the capillaries were covered with a great number of granulations, which in some spots covered the whole length of the vessels, and in other parts formed round masses, placed between the tubes of the cerebral substance. The brain contained numerous globules of blood infiltrated into its tissue; the softened spots were very circumscribed, and, in the parts isolated from them, the tissue of the organ presented no granulations, but appeared in its normal condition."

On the Action of Veratrine in Diseases of the Eye; by F. Terrier (d'Angers), M.D.—The author prescribes this substance in an ointment, or dissolved in alcohol, as follows:—

No. 1.—℞. Veratr. gr. x, Adip. præp. ℥j, Alcohol. q. s. ut ft. unguentum.

2.—℞. Veratr. ℈j, Alcohol. q. s. Adip. præp. ʒj.

3.—℞. Veratr. ℈jss—℈ij, Alcohol. q. s. Adip. præp. ʒj.

The quantities are the same dissolved in ʒj of alcohol; they must, in both, be somewhat less for children, women, and persons with a very thin skin. Two frictions a day should be used, from five minutes to a quarter of an hour each, with ℈ij of the ointment or alcoholic solution; care must be taken not to let any get into the eye, as it produces a smarting pain which lasts several hours; after each friction the part must be carefully wiped; the frictions should be performed, alternately, for five days on the forehead and three days on the temples, and the parts must be washed once a day with a bit of linen moistened with the solution.

Topical Action.—During the friction, or in general immediately after, the patient experiences slight heat, prickings, and tremors, compared by him to an electric shock, or rather to numerous pricks with a needle; effects which vary according to the dose, the thinness of the skin, and the duration of the frictions, and which soon become less intense, so that at a later period, even with a stronger solution, they are not so marked; there was no appearance of eruption, vesication, tumefaction, nor of any symptom of intoxication, though the alkali evidently was absorbed in part.

Therapeutical Action.—These frictions seem to act in two ways: first, locally, by establishing near the eye a permanent counter-irritation, and, secondly, as an excitant of the nerves, especially of the fifth pair. The diseases in which it may be usefully applied are: photophobia; pain in the eye; loss of sight, produced by ophthalmia or other appreciable causes; amaurosis, at its commencement (amaurotic amblyopia); and sometimes in the accidents consecutive to the operation for cataract by couching.

Duration of the Treatment.—Photophobia produced by external ophthalmia generally yields to six or eight frictions; that caused by internal inflammations requires many more, the number of which it is impossible to state precisely; if, however, after employing the frictions for several days, there is no amelioration, they should be discontinued; in amaurosis the treatment must be persevered with much longer, though it is not infrequent to see, after eight days, a slight amendment, which may increase or remain stationary; finally, it may happen that a favourable change takes place after the cessation of the frictions, though they produced no amelioration during their employment. The same author recommends the following remedy in amaurosis complicated with or dependent on neuralgia facialis: ℞. Rad. aconit. napel. contus. ℥j, Alcohol. rectif. ℥ij; infuse for eight days and filter. This solution may be employed in frictions either pure or mixed with any fixed quantity of hog's lard. —*Gazette des Hopitaux.*

Academy of Sciences; Sitting of the 7th July.—M. E. de Beaumont in the chair.—The Academy proceeded to elect a member to occupy the place in the section of medicine and surgery vacant since the death of Breschet. Number of members present, 54. Dr. Lallemand obtained 33 votes; Professor Gerdy, 10; Dr. Bourgery, 7; Professor Berard, 2; Dr. Jobert de Lamballe and Professor Blandin, each 1. Dr. Lallemand was consequently declared duly elected. His nomination will be submitted to the approval of his Majesty.

On the Cephalo-rachidian Liquid.—Dr. Longet, M.A.M., addressed the following letter:—"In the last sitting a learned academician (Dr. Magendie) stated that fifteen years ago Dr. Pinel-Grandchamp gave an experimental demonstration of the facts described in the memoir entitled 'New Experiments relative to the Removal of the Cephalo-rachidian Liquid, and the influence exercised by the Posterior Cervical Muscles and the Ligamentum Nuchæ on Locomotion.' But in a work recently published (1842), and in which are resumed all Dr. Magendie's researches on the cephalo-rachidian liquid, the result stated to have been obtained previously by Dr. Pinel-Grandchamp is nowhere indicated; nay, more, this gentleman, after witnessing my experiments, affirmed positively that he had never published anything on this subject; on the contrary, until the present moment he partook the general opinion entertained concerning the influence of the cephalo-rachidian liquid on locomotion. If in 1823 Dr. P. saw a guinea-pig, after the section of the soft parts of the nape of the neck, stagger when put on its feet, still he declares that he had not the remotest idea as to the cause, nor did he repeat the experiment, which was *never published by him;* and finally, that he never thought of attributing to this division the accident which, from a series of experiments, I have proved to result, and which, in a future memoir, I shall have the honour of communicating to the Academy.

On Real and Spurious Anemia, by Dr. Beau.—The state of pallor and weakness presented by individuals who have suffered from profuse hæmorrhage, is supposed to be owing to the diminution in the quantity of blood, and is known under the denomination of anemia, characterised by small pulse and noise in the arteries. This state, however, is produced by two causes very different from, though succeeding, each other, and which may be described as follows:—1° *Real anemia* appears immediately after hæmorrhage; is accompanied by pallor, weakness, small pulse, considerable thirst; the quantity of water taken passes into the vascular system, renders the blood more liquid, and increases the quantity of the circulating fluid; no noise in the arteries. 2° *Spurious anemia* or *serous polyæmia* is consecutive to the preceding; comes on two or three days after the hæmorrhage, but is not very apparent before the fifth day; it may last for a considerable length of time. Characters: pallor, weakness, pulse more developed, and sometimes stronger than before the loss of blood; beating of the larger arteries visible at a distance, and accompanied with a bellows-sound; capacity of the arteries augmented; cavities of the heart dilated, and the walls hypertrophied. These distinctive characters, consecutive on profuse hæmorrhage, are founded on clinical facts and numerous experiments on animals.

On Secondary Cataract, by Dr. Tavignot.—The conclusions of the author relative to the pathogeny of this affection are: 1° when the anterior portion of the capsule is opaque at the same time as the lens, the development of secondary cataract is not much to be feared, because the posterior portion of the capsule very rarely becomes opaque; 2° when, the lens alone is opaque, and the capsule transparent

the latter may become inflamed, and produce secondary cataract, if it was spared by the needle, or not sufficiently torn. The author, in order to displace the opaque crystalline lens, and tear the still transparent capsule to a considerable extent, proposes employing an instrument formed of a small plate of the shape and size of the pupil, moderately dilated. This plate presents a pedicle about three quarters of an inch in length, fixed at right angles on a metallic handle, similar to that of the cataract needle. *Modus operandi.*—An incision of about three lines is made over the outer edge of the circumference of the cornea; the aqueous humour once evacuated, the instrument is introduced, the edge directed upwards until it reaches the pupil, previously dilated by belladonna; it is then pressed against the capsule, and by a rotatory movement from before backwards, and afterwards from above downwards, the lens and capsule are depressed; the instrument must then be withdrawn by a motion the reverse of that employed for its introduction. By this mode of operating, not only the lens, but likewise, as Dr. Frestal has observed on the dead body, the anterior, and even the posterior, portions of the capsule may be torn.

On the Microscopic Characters of Cancer. By Professor Sedillot, of Strasburgh. This memoir, containing several observations and drawings, is intended to demonstrate the utility of the microscope in the diagnosis of cancer; in one case the disease relapsed, though it was not cancerous, as a second operation proved since it was followed by a permanent cure: in another the author was enabled to diagnosticate cancer of the stomach from the patient having thrown up cancer cells mixed with pus.*

On the Action of Ergotine in Hemorrhage. By M. Bonjean, of Chambery.—From the experiments performed conjointly with Dr. Chevallay on a sheep, a rabbit, and a fowl, the authors conclude—1° That fifteen grains of ergotine in half an ounce of water is sufficient when small vessels are wounded. 2° That the solution must be more concentrated when the vessel is larger 3° That the lint on the wound must be moistened from time to time, so as to replace the ergotine removed by the flow of blood.

Experimental Researches on the Chemical Phenomena of Digestion. By MM. Bernard de Villefranche and Barreseuille.—The principal corollaries to be deduced from the facts contained in this memoir, are—1° The peculiar digestive action of the fluids poured into the gastro-intestinal tube may always be determined by their mode of reaction; thus the gastric juice dissolves only azotised substances, owing to its acidity, but if it is rendered alcaline, it becomes like the saliva and the pancreatic juice, only capable of assimilating amylaceous substances; on the other hand, these two last when acid, act solely on azotised alimentary principles. 2° The remarkable property possessed by these three fluids, of assimilating fecula when alcaline, and dissolving meat and gluten when acid, depends on the presence of an active organic principle, identical in the three; and what proves this is, that when this principle is precipitated by the action of caloric, they form nothing more than an acid or alcaline liquid as the case may be, without any action whatever on amylaceous or azotised principles. 3° The chemical modifications that food undergoes in the stomach and intestines are produced by an active principle, always the same, but which produces a different effect according as the liquid, in which it is contained, is acid or alcaline. 4° Not only gastric juice (as advanced in a previous memoir) contains two useful principles, its organic principle and its acid reaction, but likewise saliva and the pancreatic fluid present two essential elements, viz.:—their *organic principle and their alcaline reaction.* 5° Artificial gastric juice, obtained by infusing from twenty to twenty-five fresh pancreases, taken from fowls, in ℔j water, for one and a half or two hours, at a temperature of from 95° to 104° F., is of a slightly opaline or citrine colour; no peculiar odour; of a sweetish taste; analogous to the white of an egg dissolved in water; dissolves meat quicker than the normal gastric juice, owing to its acidity. 6° If this identity is established by subsequent observation, it will no longer be necessary to open the stomach in order to procure gastric juice.

* This mode of investigation is useful, as by it the physician may, as Professor Sedillot, form a positive diagnosis in cases, which otherwise would remain doubtful, and the surgeon may be enabled to ascertain the true nature of the affection, and say whether a relapse is to be feared or not.—G. de B.

Medico-Legal Researches on Arsenic; by M. Blondlot.—The author states that two modifications ought to be made in Marsh's apparatus: 1° In destroying the animal matter by sulphuric acid, as recommended by MM. Flandin and Danger, the operation should not be continued until a light friable charcoal is obtained, but should cease as soon as the mixture presents the consistency of paste; water must then be added, and a current of chlorine gas made to pass through the solution, so as to remove all the organic matters; finally it is this liquid which must be made to act upon zinc. 2° Marsh's apparatus should terminate in Woulf's tubes, in one of which the zinc, in a spiral form, should be placed so that merely by elevating or depressing it the current of hydrogen gas may be augmented or diminished, as by this means the liquid will act on more or less of the zinc plate.

On the Ioway Indians; by M. Jacquinot.—In a previous communication the author stated that the tribe presented all the characters of the American race, and remarked the analogy which existed between them and the inhabitants of the Polynesian Islands, and especially the New Zealanders. Dr. Serres, on the contrary, asserted that the men presented the Scandinavian type, whereas the females offered the Mongol. In the present memoir M. Jacquinot, founding his opinion on the zoological characters, that is to say, those drawn from the outward man, concludes that they are very different in the two races named; and he is convinced that both men and women are of the same race, the only difference being that the latter are inferior in a physical point of view, a fact recorded by numerous travellers as existing among uncivilised nations, and which the author himself had an opportunity of observing among the Polynesians, and especially the inhabitants of the Marquesas; that the identity between the Ioways and the tribes inhabiting the valley of the Mississippi is an allowed fact; finally, M. Jacquinot concludes by some considerations on the origin of the American tribes, by which he is led to admit what he hopes to be able to prove in a subsequent memoir, viz., that America existed as soon as the other parts of the world, that its population is primitive, and that it has undergone the greater part of the revolution noticed by history as having occurred in the old world. Dr. Serres still considers this opinion to be erroneous, from the author having founded it on the external characters, neglecting entirely those furnished by the study of the skeleton and the internal organs, by which alone an exact determination of human races can be obtained. Dr. Serres, at the same time, informed the Academy that he hoped in the next sitting to read a memoir on this subject.

M. A. de St. Hilaire, M.A.S., addressed from Montpellier an article relative to the antiquity of the American races, which contains opinions contrary to that announced by M. Serres, relative to the analogy between the Bolocudos and the Mongols. The author states that after studying attentively the natives near Rio Janeiro and the Chinese, he remarked, that the only difference between them is that the face of the latter is flatter and larger than that of the former.

On the Inhabitants of the Marquesas, by M. Le Batard, Surgeon in the Navy.—The author studies their physical characters, measures the different dimensions of their heads, and concludes that the form of the head is not so perfect as in the Caucasian race; that this difference, though only slight, coincides with a degree of intelligence somewhat inferior to the Europeans; that the inhabitants of the islands of the Pacific Ocean form, by their language and their general organisation, a primitive and a separate group, which may be denominated the "oceanic race."

Academy of Medicine; Sitting of the 6th July.—M. Caventou in the chair. Dr. Ferrus remarked, that he had attended Corvisart's Clinical Lectures in 1798, and that he was certain that if the intestines were not opened in every case, this was done whenever any symptoms of disease had existed in the digestive organs.

On Epizootics.—M. Dupuy read a memoir entitled "Mon dernier mot sur les Epizooties," in which he mentions the danger attendant on the use of bad meat, and considers that it is wrong, and productive of great loss, to destroy an animal in order to save the rest of the flock. M. Renault does not consider the destruction of the animal in the same light as M. Dupuy; numerous proofs may be given as to the utility of such a measure; the following, however, may be quoted as one of the most recent:—from 1828 to 1840 an epizootic of typhus declared itself in Southern Russia, and invaded Gallicia, Moravia, Austria, and Bohemia, where no preventive measures were had recourse to; on the contrary, in Prussia, Wurtemburg, and Baden, where the animals were killed, the disease was not propagated. M. Barthelemy inquired what measures M. Dupuy intended to substitute. M. Dupuy replied, that they would be given in another memoir. As to the epizootic mentioned by M. Renault, it was not typhus, as none of the characteristic lesions of that disease existed; but serious disturbance existed in the spinal marrow at the roots of the sensitive and motor nerves, where pustules similar to those of variola were discovered. M. Hamon mentioned the accidents which follow the use of bad meat, and the necessity of putting a stop to its sale.

Discussion on Typhoid Fever, arising out of Dr. Gaultier de Claubry's memoir, read at the sitting of the 24th June.

Dr. Rochoux: Before replying to the author, I will briefly answer Drs. Merat and Castil. The former is not altogether in the wrong, as my critical remarks on pathological anatomy ought not to have gone beyond 1804, at which epoch the work by Prost, so extraordinary and yet so seldom consulted, was published; however, I maintain, that before this nothing was printed in France, on the pathology of fevers, which may be considered of any real utility. The latter stated that all is relative in this world, and that medicine does not form an exception: I, on the contrary, say, all is absolute in the universe, in medicine as in every thing else. Are we not an absolute number of individuals within these walls? Has not each of us in his pocket an absolute number of pieces of money? and have we not an absolute number of organs? Has not each of these organs an absolute number of atoms? The consideration of objects in a relative sense indicates the weakness of our minds, since all is absolute here below; and while the former is productive of doubt and confusion, the latter, which is nothing more than the Epicurean system, leads to certainty in the natural sciences. With respect to the arguments presented by Dr. Gaultier de Claubry, he was right to establish generalities, since it is by them alone that we can form true principles. These generalities are founded on three important distinctions: the contagion of typhus, the nature of the eruption, and the duration of the disease, which are contrary to the identity of the two affections, as stated by Gaultier de Claubry. As to the facts quoted, they offer no weight, considered as a proof of contagion, for, if typhoid fever is contagious, why does it attack medical or law students during the first year of their studies? What a difference between this disease and the typhus which, in 1815, attacked indiscriminately individuals of both sexes and of all ages? Again, how very different from rubeola and variola! While speaking of variola, I cannot help saying, that I cannot imagine how any author could assimilate the lesions of Brunner's glands with varioloid pustules. Professor Chomel, whose opinions on scientific subjects are of such weight, shewed the groundlessness of this doctrine, founded on the fact that dothinenteritis, like typhoid fever, attacked an individual but once in his life. The reason of this is, the aptitude to contract typhoid fever diminishes with age, since, after 40 or 50, it is no longer seen; therefore, it is not astonishing that no relapse has been observed. This is not the case with variola, since it may take place at all ages, except when the person has been vaccinated, inoculated, or previously affected with the disease. To conclude, it may be asserted that facts, generalities, and reasoning, are contrary to the opinions

of Dr. Gaultier de Claubry; besides which, Aristotle, Seneca, and all ancient writers, consider the majority of but very little moment in scientific subjects; and if Dr. Gaultier de Claubry has for him Drs. Britonneau, Leuret, Gendron, Putegnat, Bricheteau, Huret de Tancrel, Lombard, Alison, Patris; in the opposite camp we met with Drogart, Gerhard, Bischopp, Schatenck, Tweedie, Grenet, Montault, Valleix, and a short memoir read by me in 1832. In short, truth cannot be put to the vote, and he who finds it is obliged to inquire if many others are of his opinion.

Dr. Dubois d'Amiens read a manuscript in which he endeavoured to prove the two following propositions:—Typhus and typhoid fever are identical, and differ only in intensity; the facts recorded are not sufficient to prove that typhoid fever is contagious.

GARLAND DE BEAUMONT, D.M.P., B.L. & S., &c.
Honorary Physician to the Spanish Embassy.

PROGRESS OF IRISH MEDICAL SCIENCE.

(FROM OUR OWN CORRESPONDENT.)

Dublin, July 19.

Case of Amputation, with Clinical Observations; by Mr. Ellis. The amputation case at Jervis Street Hospital, under the care of Mr. Ellis, of which I gave a short outline a couple of weeks ago, as far as the progress of the case then permitted, again presents itself for consideration, occurrences of an interesting and, at that period, entirely unexpected nature having since taken place. On the 6th of July, the day after the last report, the patient complained of heat in the outside of the knee, extending up the thigh in the same course; the pulse was quick and sharp; the tongue furred.

An anodyne draught produced a good night's sleep, but the sense of heat in the limb increased, and was followed by an erysipelatous blush up the outside of it and round the stump, the face of which now assumed a somewhat sloughy appearance; this continued to spread, large vesicles containing a dark ash-coloured fluid appeared round the stump, the bursting of some of which exhibited a gangrenous condition of the parts beneath. In a day or two after an abscess was discovered at the outside of the knee, which discharged itself along the tracks of the ligatures. The sloughing process progressed for some days, during which fermenting poultices were applied, and tonics, including quinine, and beef tea were administered, with an oil draught, which the state of the bowels rendered necessary. Some of the ligatures came away on the 11th, the sloughs still continuing to separate, and on the 13th these had all fallen off, leaving the stump with a clean granular surface, the pulse having lessened in frequency, and the patient looking better. The separation of the sloughs was necessarily followed by protrusion of the bone, a portion of which was removed on the 15th, since when the condition of the patient has been most satisfactory.

MR. ELLIS'S CLINICAL OBSERVATIONS.

Lecturing at this season, gentlemen, is not the usual custom; but from the degree of interest attached to this case there appears to be a sort of necessity for my offering a few observations. As the greater number of you are juniors, let me, in the first place, remind you of the division that has been made of fractures.

The lecturer having here briefly alluded to this portion of the subject, proceeded to say—Keeping this classification in view, if called to a case of compound fracture, and a question arises whether amputation is to be performed or an attempt made to save the limb, you are to consider not alone the amount of local injury, but also the age, circumstances, rank in life, &c., in which your patient is placed. In reference to age, as a general rule it may be decided that in a doubtful case occurring in a boy of eight or ten years old, for instance, you would not remove the limb, for though the case be a bad one as regards the amount of injury sustained, yet the powers of recovery at this age are considerable, exceeding very far indeed those of more advanced life. Well, then, we shall say, under circumstances of this kind, you would not operate on the child; you would have much hesitation in doing so in a young man; while in an old person you would at once have recourse to it. Let us for a moment consider the question in a mercantile point of view, if I may use the phrase, and see the amount of use available to the child of eight years by a saving of the limb. To him it might be estimated at a period of fifty or sixty years, while suppose your patient to be an old man, arrived at this latter age, his limb would not be worth ten years' purchase, so that his parting with it would be comparatively a trifling loss, while in attempting to retain it you expose his life to considerable risk.

Suppose again you have two patients of the same ages, the one a young nobleman, the other a slater, with an equal amount of injury in each, and so great that in attempting to save the limb you do so at the risk of life; you would amputate in the case of the young nobleman, because by so doing you would have, in the first place, almost a certainty of saving his life, and in the next, he can spend a pleasant life with one leg; besides, he can afford to get an artificial one of the most expensive kind; while to the slater his limb is of almost equal value with his life, and a wooden leg would be of comparatively no use to him as an organ of locomotion. Now let us take up an ordinary hospital case. If you amputate soon after the occurrence of the accident, you reduce the case to one of simple incised wound, while, if you do not interfere, there follows, after a species of injury such as we are discussing, a succession of dangers. In forty-eight hours from the occurrence of the accident, you frequently have gangrene established, and this occurring in lacerated structures is not likely to be limited. The attendant fever, too, at first of an inflammatory character, soon becomes typhoid; then, if your patient does not die in a few days from these causes, he is exposed to the risk of hæmorrhage on the separation of sloughs, to the consequences of extensive suppuration, and the tedious separation of fragments of bone, and most likely, if the leg be the subject of injury, to deep-seated abscesses. Thus he becomes ultimately run down. Again, in eight or nine days after the accident there is a great liability to the occurrence of tetanus, while if you amputate early your patient is pretty sure to escape it. I do not mean to say that there is no instance on record of tetanus occurring after the operation, but it rarely happens after a simple wound.

These dangers, then, are all arrested by early amputation, and a consideration of them should act powerfully on the mind of the surgeon in making his decision, and should oblige him to divide the responsibility by looking for a consultation.

Erysipelas, you are aware, occasionally comes on after operations, and if, as in the present case, after amputation, the stump is usually much disfigured from its partaking of a gangrenous character.

The soft parts you saw sloughed away, but the bone not partaking in the inflammation; a conical stump is the consequence, to avoid which we have removed a portion of the bone, and I think we may expect eventually to have a very good stump. Any sharp angles that remained after the saw, were removed with a rasp; but even had this been omitted, the absorbents would in a few days have removed them. Lymph will be shed on the smooth surface of the bone, and into this vessels will shoot, forming granulations, so that the entire surface will soon present the homogeneous appearance of an ulcer. The end of the bone, you have observed, comes over the surface, but the weight of the limb will not have to be borne by the extremity of the stump; it will be supported by the patella, so that there is no danger of ulceration of the new skin occurring hereafter from pressure.

Remember, that in choosing the time for operation, the first opportunity for the purpose is included in a period of thirty-six hours from the occurrence of the accident, previous to the occurrence of inflammation; that after this has supervened the operation is improper. All military surgeons agree in saying, that the patient generally dies if it be performed in this stage. Do not amputate, then, if you lose the first opportunity, until suppuration has been established; but remember the risk your patient is exposed to by being allowed to lie over for eight or nine days. I shall reserve any further observations, gentlemen, until the issue of the case has been decided.

PROGRESS OF GERMAN MEDICAL SCIENCE.

By SIGISMUND SUTRO, M.D.

On the Urine in Bright's Disease; by T. Schlossberger, M.D., late Assistant-Teacher at the Chemical Laboratory of Edinburgh, and Professor of Chemistry at the University of Tübingen.—Since the discovery that albuminuria is often combined with the so-called Bright's disease of the kidneys, the presence of albumen has been generally considered as an essential sign of this complaint, and this opinion has been apparently further confirmed by the action of the mineral acids. These delusions have now ended since the chemical analysis of urine has been so much improved and varied by the methods of Simon, Becquerel, Lecannu, Golding Bird, and others. The presence of albumen in the urine instead of being, as was usually supposed, an unusual occurrence, is now proved to be so common, that its absence is most deserving of notice. This fact has made it very improper to conclude, from the presence of albuminous urine alone, that any structural alteration of the kidneys has taken place.[1] In order to supply this deficiency in diagnosis, on the part of chemistry, recourse was had to its important auxiliary, the microscope. T. Voger, Scherer, Simon, and others, have lately discovered in the urine, during Bright's disease, pipe-like corpuscles, which appear, according to the latest representation by Henle, as group-like formations in the finest tubes of the cortical substance. Dr. Schlossberger found in the urine of persons labouring under Bright's disease, the same pipe-like cells in considerable quantity, and of various and very different sizes; they were mostly filled with Gluge's exudatory (inflammatory) globules, others were filled with molecules, perfectly identical with the single corpuscles from the aggregation of which Gluge's globules were formed. These isolated molecules probably give rise to larger globules by means of subsequent agglomerations, or perhaps the former arose from the dissolution of the latter. The diagnostic value of these plastic formations, as regards the renal degeneration in question, seems to the author to be very doubtful, since they may be equally found in the urine of persons suffering from primary or consecutive nephritis, if it occasions any group-like exudation. Lehman and Scherer have already discovered the same pipes in the urine of patients suffering from scarlatina. Thus the presence of albumen and pipes does not suffice to fix the characters of Bright's disease. Scherer mentions several analyses of Bright's urine in his chemico-microscopical researches (Heidelberg, 1843), according to which the sum total of solid constituents is considerably diminished, notwithstanding the presence of albumen; thus, he once obtained from 1000 parts of urine in Bright's disease only 12·4 solid parts; another time only 11·7, from which even two to three parts of albumen must be deducted. The normal urine of healthy persons exceeds that quantity two, three, and even four-fold. If this paucity of solid residue had been constant in Bright's disease, it might have been considered as pathognomonic, together with the presence of albumen and pipes; the more so, as the albuminuria generally only occurs in severe inflammations, or in violent, particularly exanthematous, fevers; in which diseases, the solid, and particularly the azotised constituents of the urine, exceed the normal average in consequence of the increased sanguineous metamorphosis. Becquerel's observations make the urine of Bright's disease appear to be anemic; but out of his seven analyses he once obtained urine with 24·5, and at another time with 35 parts of solid residue in 1000; the latter urine was in a case of acute disease, with fever. Simon, however, found, in several analyses of this urine, 33·51 to 66 as the sum total of solid constituents; even after deducting for the albumen which is often present in considerable quantity, the solid residue is very nearly normal. The above

[1] Bastow, who examined the urine of the first patients treated by Bright himself, even then mentioned that the healthy urine almost always contains albumen, which may be increased by many trivial causes.—*Bright's Clin. Reper.*

shows that the sum total of the solid constituents of the urine is very variable in Bright's disease, often approaching anemic, often normal, and occasionally the loaded state of urine in fever. The different casualties, and the stage and character of the disease, explain this variation. But another question is, whether the proportion of the normal urinary constituents does not undergo a material change in Bright's disease? Before, however, discussing this question, the author gives the analysis of some urine, which partly refers to the point in question, and partly excites interest on account of the state of the patient when it was excreted. The author begins by reporting the case, in order that the nature of the morbid product may be better appreciated.

Case.—The patient was a basket-maker, æt. 19, of scrofulous habit, and bloated appearance; both his parents died of general dropsy, caused by an organic affection of the liver in his mother. He was not aware of having suffered any previous disease. Last Easter he was suddenly seized, probably after taking cold, with colic, and subsequently with œdema of the legs, and he found the urinary excretion greatly diminished; four weeks afterwards dropsical swelling of the abdomen appeared, which extended slowly, but steadily. The urine continued scanty, but clear, till the middle of August. From that time it became high coloured. Anti-hydropics were administered to no purpose. The disease pursued a very chronic course, when suddenly, one evening in September, cerebral symptoms appeared, with maniacal paroxysms, and perfect unconsciousness. These paroxysms lasted about twelve hours, after which the patient regained his previous state.

The author analysed the urine, discharged immediately before the paroxysms, in Scherer's laboratory, and at the same time his friend, Dr. Menges, of Nassau, analysed the urine excreted in the first hour after the paroxysms, and has kindly permitted the publication of the result. 1° The urine discharged in the evening before the paroxysms, amounted to about ten ounces. It was pale yellow, weakly acid, rather dull, and contained distinctly the above described pipes, besides epithelium scales. After standing eight hours, a considerable sediment of uric acid was deposited. Spec. grav. 1011·6. It was evaporated in a water-bath, and dried at 100° C. without further loss of weight. Out of 1000 parts, 58·06 remained as solid matter. When this was incinerated, 9·77 of salts remained unaltered by fire. On coagulation by boiling (with the necessary precautions) the result was 17·9 albumen. After a deduction for the urea (fixed by nitric acid, and amounting to 7·6) the filtrate furnished 19·5 of matters soluble in alcohol, consisting of extractive matter with different salts; 12·7 of matters insoluble in alcohol, 2·6 of which were uric acid and mucus, so that 10·1 remained for the earthy phosphates and sulphates, and the insoluble extractive substances. 2° The urine excreted after the cerebral paroxysms, and analysed by Dr. Menges, displayed similar physical properties, as is shown by the following comparison:—

No. 1.—*Urine before the Paroxysms contains in 1000 parts.*

Water	942·0	Water . .	942
Albumen	17·9	Solid residue	58
Urea	7·6		——
Alcoholic extract with salts	19·5		1000
Uric acid with mucus . .	2·6		
Watery extract with earthy phosphates	10·1		

No. 2.—*Urine after the Paroxysms contains in 1000 parts*

Water	931·3	Water . .	931
Albumen	17·0	Solid residue	69
Urea	4·5		——
Alcoholic extract with salts	20·5		1000
Uric acid with much mucus	5·2		
Watery extract, with phosphates, &c.	20·9		

In both analyses, a high sum of solid constituents was thus obtained, even after making a deduction for the albumen. In Becquerel's, as well as in the above analyses, the quantity of urea is found diminished, for in healthy urine it generally amounts to half of the solid constituents. Berzelius and Lehman found 30 parts of urea in 60 parts of solid residue. Lecanu also fixed for normal urine, 30·27 parts of urea in 1,000. (But since he did not fix the total amount of solid residue, his results are of less comparative value.) In the analysis, as given above, the urea only amounts to about one-sixth, and in that excreted, 16 hours after, to one-eleventh of the whole solid residue (after a deduction has been made for the albumen). Becquerel also found the urine in all his analyses in cases of Bright's disease (with one exception), to amount only to one-third or less, of the whole solid residue. Thus, a relative and absolute diminution of urea seems to be pretty constant in Bright's disease. But the author does not yet draw any inferences, preferring to wait the results of further experiments. Only renewed researches can discover whether the chief source of diminished urea is to be sought in an alteration of the blood, in a morbid organic change of matter, or in a degeneration of the secreting organ itself. But in many cases, deficient metamorphosis does not seem to be the cause. Urea is produced, but not excreted in sufficient quantity, and thus the blood is charged with this remarkable excretion. The blood thus altered, seems to exert an intoxicating effect on the brain, which the author has observed in several cases of icterus, in which similar nervous symptoms occasionally appear. The existence of urea in the blood of those suffering from renal degeneration, is no longer doubtful after the experiments of Babington, Christison and Simon, though others have sought it in vain. But one positive assertion of a credible authority has more value in such questions than a host of negative results. Even in the serum, which easily exudes in the cerebral ventricles during Bright's disease, urea has several times been found. The author himself observed such a case, when assistant-physician to the Catharinen Hospital, at Stuttgardt, he distinctly found urea in the serum, which had been effused into the cerebral ventricles. The quantity of the other solid constituents seems to be also subject to irregularity. Thus the quantity of uric acid is greatly diminished, according to several chemists, whilst in the above analyses it considerably exceeds the average. In the present methods, however, several sources of error are concealed, and will probably be removed by future progress.

PROGRESS OF ENGLISH, ITALIAN, AND AMERICAN MEDICAL SCIENCE.

[The following are the principal articles of interest to our readers in three numbers of the "Medical Gazette."]

Hæmatemesis from swallowing a Copper Coin.—Mr. Dicken relates the case of a boy, ten years of age, who swallowed a copper coin while playing, which however produced little inconvenience for several days, the boy complaining occasionally only of a sense of weight and uneasiness in the epigastric region, rather towards the right side, and a sense of distension after meals, which generally subsided in the course of three or four hours. Nearly a month after the accident, while in bed, he was suddenly seized with sickness, and instantly vomited a large quantity (more than a quart) of fluid arterial blood. The hæmorrhage continued at intervals through the night, but was checked by giving large doses of tartrate of antimony, which considerably depressed the action of the heart. On the next day the bleeding again recurred to a great extent, and after throwing up a considerable quantity of dark fluid, he became sensible (as he described it at the time) of something passing the stomach, and thence into the bowels. A temporary relief was obtained, and sanguine hopes were entertained that the mischief was arrested, but the hæmorrhage again recurred, and he suddenly sank on the evening of the succeeding day in a state of collapse. The body, which was examined thirty-six hours after death, presented externally a complete state of paleness from draining of blood. On opening the stomach a circular ulceration of the mucous surface was observed, corresponding exactly in size to the halfpenny, but at a considerable distance from the pyloric orifice. The surrounding coats of the stomach did not exhibit any unusual vascular appearance, nor were any traces of inflammatory action observable in any other part of the organ. The coin had evidently escaped through the pylorus. On tracing carefully the track of the whole alimentary canal from the duodenum to the rectum, the halfpenny was discovered at the very termination of the colon, lying loose, and easily removable; in fact, its situation was such that it would in all probability have been voided by the next evacuation from the bowels. Not the slightest alteration of structure, nor any abrasion of any other part of the mucous surface of the alimentary canal, existed, nor any other morbid appearance.

Encysted Empyema.—Mr. Henry Lee details the post-mortem appearances in a case of this kind, which occurred in a man, 59 years of age, who had laboured under the disease for twelve years. The malady commenced in the form of inflammation of the right side (pleurisy?), which terminated in suppuration, and the formation of a fistulous opening which remained till death. Considerable quantities of pus were at different times discharged, but it occasionally happened that the opening became nearly closed, and great oppression of the breathing would then be experienced until a free discharge of pus took place. When the external opening was larger than usual, a quantity of air would sometimes enter, and this the patient could again expel at pleasure with considerable force. During a few weeks preceding his death, a very considerable quantity of blood was passed with the discharge from the side. On examining the body after death, the following appearances presented themselves:—The lower part of the right side of the chest was compressed, and from this point the upper part of the body was inclined towards the right side, presenting a similar appearance to that which would be produced by a lateral curvature of the spine. Between the anterior extremities of the fifth and sixth ribs, upon the same side, were two fistulous openings, with their edges inverted, and discharging a bloody fluid. The two layers of the right pleura were connected by numerous bands of adhesion. Between them, in the upper part of the chest, were contained about six ounces of transparent serum, while in the lower part a cavity presented itself, containing a dark gangrenous fluid, and circumscribed by extremely firm adhesions. This cavity was about six inches long, and four inches broad, and communicated freely with the exterior of the body by means of the sinuses above mentioned. The pleura, in this situation, was in some places three lines in thickness, and was lined upon its internal surface by a soft vascular layer, from which the bloody fluid in the cavity had apparently been secreted. The structure of the lung in contact with the diseased pleura was condensed to the depth of two or three lines only, but in other respects did not differ from the remainder of the pulmonary tissue. The lower surface of the right lung, and the upper surface of the right lobe of the liver, were firmly adherent to the diaphragm. The left lung presented soft adhesions over its whole surface. On both sides the lungs were greatly emphysematous, and their structure was everywhere loaded with serous effusion. In several situations small masses of calcareous matter presented themselves, but in no part could any tubercular deposit be discovered. The pericardium was universally adherent. The heart was healthy, with the exception of the tricuspid valve, the aperture of which was dilated.

Preparation of Phosphoric Acid from Bones.—Dr. Gregory recommends the following process for obtaining pure phosphoric acid from bones:—Having removed the whole lime by means of sulphuric acid, and evaporated the filtered liquid (filtering again if any sulphate of lime separates during the evaporation) to the consistence of syrup, a few drops of sulphuric acid are added, to make sure that no lime remains. Of course, if turbidity ensue, the lime has not been completely separated; and the addition of sulphuric acid, filtration after adding some water, and evaporation, must be repeated, till the syrupy liquid continues quite clear when sulphuric acid is added. The liquid then contains only the phosphoric acid, magnesia, and the excess of sulphuric acid. It is concentrated and heated in a covered platinum crucible, until the whole of the sulphuric acid has been expelled, and the residue has acquired a low red heat. On cooling it forms a glass, perfectly colourless and

transparent, which contains only phosphoric acid and the magnesia of the bones. This glass, when boiled with water, dissolves rather slowly, but completely. When the solution is again concentrated in a capsule of platinum, until most of the water is expelled, and the temperature rises to between 595° and 600° F., it suddenly, while hot, becomes turbid from the separation of a peculiar phosphate of magnesia. At the same moment the phosphoric acid begins to crystallise like the granular sugar deposited in honey, a form ascribed by Peligot to the bibasic or pyro-phosphoric acid. If the same temperature be kept up for fifteen minutes (and it can be ensured without a thermometer by heating to that point, and no further, at which the acid begins to vaporise with the water in the open capsule), the whole of the magnesia separates in the form of a powder, which is quite insoluble in water or acids. When cold, the mass is digested with water, which dissolves the phosphoric acid, leaving the phosphate of magnesia as a heavy, fine, snow-white powder, of a faint silky lustre. *The filtered liquid is free from every trace of magnesia*, and may be considered as pure phosphoric acid. Of course, however, if the bones contained chloride of sodium, a trace of phosphate of soda would remain. In that case the burnt and powdered bones ought to be boiled with water, to remove any soluble chloride. There is no difficulty in the execution of this process; it is only necessary to keep up the heat of about 600° for twelve or fifteen minutes, but not to go beyond that temperature, because a stronger heat would again, no doubt, produce the glass formed as the first fusion, which, as has been seen, is entirely soluble in water. The acid is easily tested for magnesia by diluting and super-saturating with ammonia, when, if magnesia be present, it very soon appears as ammoniaco-magnesian phosphate.

Poisoning by Prussic Acid.—Mr. Hicks narrates at some length, the particulars of a case of accidental poisoning by prussic acid. The patient, a female, twenty-two years of age, lived ten minutes after his arrival. When he saw her, she was lying on her back perfectly insensible, the teeth clenched, foaming at the mouth, and the face so greatly congested as to be almost purple; the breathing was slow, laborious, and at long intervals, the pulse gone, and the action of the heart but feebly to be felt; the eyelids were partly closed, and the eyes appeared as if pushed forward between them, while the pupils were dilated, and quite insensible to the stimulus of light; the whole body was under such strong spasmodic action, that the head seemed buried between the shoulders, and the arms nearly turned round by the action of the pronators. There was neither emprosthotonos nor opisthotonos. Stimuli, medicinal and dietetic, were administered, but it is doubtful whether any was swallowed on account of the spasmodic condition of the muscles of deglutition. Cold affusion was also used, but in vain: the breathing became gradually slower, and in less than ten minutes after his arrival the patient died—death appearing to be caused by the perfect inability of the sufferer to inspire, from the muscles of the chest, as of every other part of the body, being under strong tetanic spasm; the natural consequences being extreme congestion of the brain and lungs. No scream nor shriek was heard after the ingestion of the poison, but a loud gasping sound in lieu thereof. The principal appearances after death were congestion of the brain and lungs, the blood being fluid and very black. The odour of prussic acid, or rather its effects in producing a constriction of the fauces, was perceptible both in the chest and stomach, but not in the brain. Chemical analysis clearly demonstrated the presence of prussic acid in the contents of the stomach, and it was ascertained by computation, that she had taken about *nine-tenths* of a grain of the anhydrous acid.

Acute Hydrocephalus.—In the treatment of this disease, Dr. Blackmore advises general and local bleeding, practised according to the age and strength of the patient; arteriotomy he considers the most advisable plan; opening the jugular vein he says is not to be generally used. Blistering the head or neck he also recommends, and free purging. Diuretics, and mercury he regards as uncertain. The latter he says may be useful in the advanced stages of the disease.

Epilepsy.—When this disease is produced by the original constitution of the patient, it is incurable; when caused by plethora, or accompanied by symptoms of cerebral congestion, venesection, free purging with sulphate of magnesia, and aloes with colocynth, and the use of blisters in succession are advised by Dr. Blackmore. In addition, the diet should be cool and spare; the patient should not take a stronger liquor than small beer; distilled spirits and all fat meats should be strictly forbidden, and animal food should be used sparingly. The patient's diet should be milk and vegetables, and the quantity should be limited. The exciting causes should be avoided, and the passions of the mind kept under. Exposure to great heat, either from a fire or too much bedclothes is injurious. The patient must not sleep on a soft bed, but on a mattrass, with a hair pillow; when the disease is caused by inanition, the diet should be nutritious with animal food, and a little wine. There are not any specific tones for epilepsy; but—Exercise will increase the strength, promote the appetite and digestion, and a proper deposition of nutritious matter; it must be within the limit of fatigue. The action of the muscles of the arms is promoted by dumb-bells. Cool fresh air, the shower bath, and the cold bath strengthen; the patient should plunge in head foremost, and come out immediately. Washing the head with cold water thrice a day is good. A long sea-voyage has cured the habit that occasioned the disease. Superstitious remedies, influencing the mind with awe and reverence, have cured it; as eating the sacred birds among the Romans; and the *viscus quercinus*, misletoe, the oak being an object of great veneration in the time of the Druids. Bitters are employed; they possess efficacy, as is seen in intermittent fevers; but cinchona is scarcely ever successful in epilepsy. Iron in any quantity or form is not successful; it is thought a tonic. Dr. Blackmore has used half a drachm of the precipitated carbonate with valerian, without bad effects; when given freely it has carried off worms, and so has done good. Tonics are not to be trusted to. Arsenic has been given; it was thought to be a tonic by Cullen, but it is not. Argentum nitratum is also thought a tonic, and a cure for this disease; Dr. Blackmore has tried a quarter of a grain in a pill without success; it must be given with caution. One patient came to take a grain and half daily; then a violent diarrhœa came on; the fits were suspended for six months; yet there was organic disease in this case, which led to a subsequent loss of the mental faculties. The cuprum ammoniatum is praised; a large dose has induced violent vomiting and purging. Oxydum zinci produces no effect; sulphas zinci is a better astringent. Hydrargyrum, particularly calomel, purges, and does some good. In the cure of this disease no one remedy, nor all of them together, can be relied on. The fœtids as valerian, assafœtida, musk, castor, camphor, are thought to be antispasmodic. One patient took valerian, and the fits ceased; it was omitted, and they returned; it was given again with the same success. Dr. Fothergill thought these medicines acted, in epilepsy, by disordering the stomach and impairing the appetite. He was a man of genius and observation, and his theory is deserving of credit. Opium may do good in some cases of this disease; it is tried with success in asthma, which is a violent spasmodic disorder, and in hysteria.

Hysteria.—In the treatment of this *opprobrium medicinæ*, Dr. Blackmore trusts to well-managed diet and exercise, cold bathing, and the shower bath, and the patient being much in the open air, which he says strengthens the sufferer, and lessens irritability.

Latent Scarlatina.—Under the title, 'Record of Cases,' Dr. Mayo describes two cases of scarlatina, in which the exanthem remained as it were latent, and which terminated fatally soon after the disease commenced. The treatment consisted of free purgation, and the exhibition of stimulants. There was not any examination of the body made in the first case after death; the appearances in the second, that of a boy seven years of age, were those of cerebral congestion and effusion.

Dislocation of the Shoulder.—Mr. Collier describes two cases in which dislocation of the head of the humerus into the axilla took place from sudden and powerful muscular action.

Tetanus.—The following is the plan of treatment recommended by Mr. Stafford in this formidable disease:—If the patient be plethoric, one general bleeding from the arm may be had recourse to, according to the violence of the symptoms. Leeches may be applied along the whole course of the spine, and more particularly at those spots where the muscles are most spasmed. The extract of belladonna may be rubbed on each side of the spine, and more particularly at the spasmed portions, whereby the paroxysms may be prevented. Purgatives may be administered, and the contents of the alimentary canal evacuated gradually, as recommended by Mr. Abernethy, by giving doses of calomel and jalap every three hours, and if that should not be active enough, one drop of croton-oil. When the bowels have been sufficiently relieved, then calomel and opium may be prescribed as for iritis, and persevered in until the mouth becomes sore. Should the disease become chronic, counter-irritants may be employed, such as blisters on each side of the spine. Should the paroxysms of spasm be very violent, opium, the tincture of cannabis sativa, or the extract of belladonna, or any other antispasmodic, may be exhibited internally, according to the best judgment of the medical attendant. Soothing remedies may be employed to the wound, such as a strong solution of opium, hyoscyamus, poultices, &c. If there be tension of the nerves they may be divided, and should there be a peculiar state of the wound, causing more than ordinary irritation, or should it be impossible to save the limb, then amputation may be performed.

Serious Injuries unattended with much Constitutional Disturbance.—Mr. Meade has narrated four cases which are interesting on account of the slight degree of attendant constitutional irritation, the non-occurrence of which he thus explains. "It seems that in very extensive injuries, where several distinct parts of the body are hurt at the same time (when the shock is not so great as to destroy life before reaction takes place, and in which no internal and vital organs are seriously injured), the injury in one part acts as a check upon that in another, producing a sort of counter-irritation, which keeps down violent inflammatory action, and sympathetic fever." The first case is that of a robust powerful man, who had met with severe injuries while blasting a rock with gunpowder. When seen by Mr. Meade, both hands were completely shattered; the fractured extremities of the radius and ulna were exposed on one limb, and only remained attached to a few blackened fragments of the wrist and hand; while the mutilation of the opposite limb was not much less. The integuments of both arms, as high as the elbow, were much lacerated and burned; the skin, and in many places the cellular tissue beneath it, being infiltrated with dirt, fragments of stone, and gunpowder. The head and face were much injured. The features were so blackened and cut that it was difficult to recognise them. Sight appeared, at first, to be totally destroyed, the sclerotica and cornea of both eyes, as well as the lids, being extensively lacerated with fragments of stone, and blackened with gunpowder. On separating the lids the man could see light with the left eye, but the sight of the right was quite gone. Vision was probably destroyed at once by concussion of the retina, as the globe of the eye was not apparently penetrated by any of the wounds on its surface. There were several wounds in the scalp, and one deep cut on the front of the left leg. On recovering from the immediate shock, amputation of the arms was performed, and the other wounds cleansed and dressed. He recovered without a symptom of constitutional disturbance. The stumps united with rapidity; one was quite well in a fortnight, and both arms completely healed in three weeks. The chief sufferings arose from the injury to the eyes; considerable inflammation occurred in both of them, affecting all the external proper tunics, and being very protracted in its course. In the right eye, matter formed in the anterior chamber, and between the layers of the cornea, and complete disorganisation of the globe took place. In the left, very considerable inflammation of the cornea and sclerotica occurred, extending to the iris, which required for its removal the repeated local abstraction of blood, and the long-continued administration of mercury, so that

to keep up a slight affection of the mouth. He ultimately recovered the sight of this eye, though it still remains very imperfect in consequence of opacity of the cornea, owing, in a great measure, to the presence of particles of gunpowder which are imbedded in its substance. The next case is somewhat similar: amputation of the left arm and of the right thumb was required; one eye was destroyed, the scalp and face were extensively lacerated, and there was also a severe compound fracture of the left leg below the knee. This accident also happened by blasting rock with gunpowder. This man recovered without any febrile disturbance, or disorder of the general health. The stump rapidly healed, and the wounds on the head and leg soon closed. His chief sufferings (as in the former case) arose from the injured eye. Chronic inflammation of all the tunics occurred, which terminated in suppuration and collapse of the globe. His complete recovery was also retarded for some time by want of union between the bones of the fractured limb. The external wound soon healed, so that it became a simple fracture; but it was necessary to continue the use of splints for nearly three months before union became firm. It seemed a consequence of the complicated injuries under which the man was suffering, that there was not sufficient vigour in the constitution to effect union between the fractured bones. The third case was one of severe concussion with suspected fracture of the base of the cranium, from an accident with machinery. The man was treated, after the subsidence of the shock, by venesection, leeches, aperients, low diet, quietude, &c., and ultimately got quite well, and still continues so. The fourth case is entitled severe sprain of the sacro-iliac articulation, and is thus described. It occurred in the person of a young man who was working in a mill for the construction of machinery. A rack suspended from the roof or ceiling of the building in which he was working, and which was filled with a number of heavy bars of iron, gave way, and fell upon him. He was standing in a corner of the room, and was in a stooping position at the time, so that he received the weight, amounting to more than a ton, on the back of his head and shoulders, and was forcibly bent down into the corner with his legs doubled under him. When extricated, it was found that his head and back were unhurt, but he complained of the most excruciating pain in the right hip, and at the lower part of the back, which was increased by any attempt to move the right leg, or to bear any weight upon it. I saw him about two hours after the accident, and found him complaining of constant and dreadful agony, which he described as having the aching character peculiar to a severe sprain. On examining the part affected he referred the pain exactly to the point of junction of the sacrum with the right ilium. There was no bruise or sign of external injury over the part, except some swelling, and, in fact, he said that he had not been struck in that situation, but felt as if the injury had been caused by the weight which fell upon him forcibly doubling him up, and straining the lower part of his back. Mr. Meade could not detect any injury to the bones of the pelvis or thigh, nor to the hip-joint, and the man could move the affected limb, though it caused him an increase of pain to do so. There was great tenderness, and some swelling over the sacro-iliac articulation. The pain continued for several days, of the same constant aching character, but was unaccompanied by any constitutional disturbance. It gradually subsided, though for several weeks he could not bear to press the foot on the ground, and it was six or seven weeks before he attempted to walk. He ultimately quite recovered, and returned to work about two months after the accident: he was then still rather lame. The treatment consisted of perfect rest, with the application of leeches and fomentations in the first instance, subsequently gentle friction with soap liniment, and ultimately the application of a soap plaster spread on thick leather, supported by a bandage.

Hydrocele.—Mr. Burton has published the particulars of a case of hydrocele, in which the tumour was of very large size, and which was cured by an injection of a solution of sulphate of zinc.

The Matter of Contagion.—Berres in a paper published by the Imperial Medical Association of Vienna, and noticed in the British and Foreign Medical Review, says, contagion may consist of either dry or moist matter; the former may be in the shape of scales, scurf, or abrasions of the epidermis; and the latter a fluid, contained in vesicles or pustules; and, finally, contagion may be propagated by any secretion or excretion from the surface of the body. The essence of dry contagion exists in an aggregation of semitransparent greyish white globules, about 1-10,000th of a Vienna inch in diameter. These globules swell somewhat in water, but exhibit no further internal structure. In the moist form of contagious matter, we observe a vesicle filled with a clear fluid, which exhibits no traces of organisation; but should it become in the slightest degree discolored, then a number of greyish white, round molecules appear in the fluid. These are about 2-10,000th of an inch in diameter, and contain a small cavity, apparently filled with a delicate vapour. But should the contents of the vesicle or pustule become more turbid, then the large spherical pus-globules become visible. It is well known, that certain fluids are at one time contagious and at another totally inefficient; and the microscope has hitherto signally failed in discovering the cause of this remarkable variety of effect. From the result of his observations, M. Berres contends that all fixed contagions are, at their origin, alike in form, and that they consist of larger or smaller globules, which, in the moist variety, are surrounded by a clear fluid; moreover, that we have no data to explain the extreme variety in the effects and operations of contagion; and, lastly, that we must allow a specific life and separate existence to *contagion*, which combines itself with the globules above referred to, and employs them as the means of transport of its hidden power. He conceives contagion to be propagated in two different ways, the material and the dynamic or vital. In considering the first-named mode, our attention should be directed to the anatomical constituents of contagion, as before described, and also to the surface of the human body, as its destined recipient. He denies, or at least strongly doubts, the possibility of dry contagious matter acting through the epidermis; and even in the moist form it would require a large quantity for the necessary endosmose: We must, then, allow, that it is not the materies of contagion, but its specific life or vitality, which constitutes disease: and infection is then a dynamico-vital process, which takes place between living contagious matter, and the individuals predisposed to receive it. If this be true, it follows that contagion in all respects resembles the process of fecundation; where it is not the semen itself, but the aura seminalis, which operates on the germinal vesicle.

Cretinism.—According to Dr. Knolz, who resided for ten years among the cretins at Salzburg, in the Tyrol, the entire body of the cretin bears the marks of insufficient or irregular development. The average stature is far below that of the Caucasian race; the head is small in proportion to the size of the body, and, from its peculiar form, resembles rather that of the lower animals than of the perfect human being; as the lower portion of the face, containing the organs for the reception of food, are infinitely more developed than those allotted to the senses. The facial angle usually approaches more nearly to that of the orang outang than to that of man. The occiput is generally flat, and the back part of the skull runs parallel with the spine, as in ruminating animals. The occipital foramen, probably from deficiency of the cerebellum, lies very far back in the skull; and this, no doubt, is the cause of the head falling so far forward upon the chest. The face is usually broad and short, as are also all those features which give to the countenance its intellectual character. The eyes are sunk in the head, and widely separated; the eyelids heavy and overhanging; and the forehead retreating and low. The jaws are extremely prominent; the mouth wide, with thick sensual-looking lips, from which the saliva constantly flows over the scarcely perceptible chin. Dr. Knolz entirely denies that the dimensions of the thyroid gland afford any just measure of the amount of cretinism in individuals so affected. From the peculiar position of the spine, in relation to the thighs, the cretin's gait resembles not a little that of some of the monkey tribes when walking erect. Ipzhofen denies that the genital organs in cretins are unusually large; but Dr. Knolz confirms, in this respect, the statement of others, and asserts their excessive development to be an universal law. With respect to the physiological qualities, the digestive organs of cretins greatly preponderate in activity over the others; the whole occupation, the whole life of the cretin is centered in the enjoyment of eating, though Dr. Knolz does not think, with the Wenzels, that their digestive powers are necessarily in proportion to their enormous appetites. The liver in cretins, as in the lowest class of animals, is of great relative size. They undoubtedly possess muscular irritability, and also the faculties of thought, and of will, but in a very inferior degree. In the complete cretin, the power of speech is almost entirely, or is quite, extinct; nor does this result from deafness, for he is equally unable to learn the finger-language of the deaf and dumb. The true characteristics of the cretin are then to be sought for in the head, both in the skull and in the face; and to these may be added, the undue development of the liver, and of the sexual organs. Fœtal life in the cretin may be said never to be extinguished; he is never developed into the man, scarcely rising above the condition of the merest infant, save by the great activity of the digestive and sexual organs. In fact, they otherwise possess merely a vegetative life; and, were their appetites and power of locomotion taken away, they would be no more, observes Dr. Knolz, than warm-blooded plants. The disease of cretinism Dr. Knolz considers to arise from undue activity of the ganglionic or vegetative, with a deficiency of the cerebral, system; and not, as many have imagined, from any peculiar induration of the whole or of parts of the brain, or from rachitis, syphilis, &c.

Remarkable Case.—The following singular case of hernia cerebri, recorded by Professor Wagner of Lemberg, is published in the *British and Foreign Medical Review*. The patient, a girl of eight years of age, born of healthy parents, was observed at birth to have a small tumour on the right side of the nose, near its root. The tumour was then only the size of a hazel-nut, insensible to the touch, and covered with a skin similar to that of the neighbouring parts. Before the child was a year old, the growth had increased to the size of a pigeon's egg, and had become dark coloured and tender. Eight years elapsed before medical aid was sought. The child then appeared healthy, and all the functions were perfectly normal. The tumour extended from the inner canthus of the right eye over the cheek as far as the right ala nasi, and, passing across the mesial line, covered also a portion of the left side of the nose. It was seven inches in circumference at the base, two in diameter, and four in length; its consistence soft and pasty; and the colour brownish red, with several white cicatrices. The eyelids of the right eye were partially everted, and inflamed; while the ball itself was thrust outwards towards the external canthus. The patient complained of a dull pain, extending upwards to the brain, when the tumour was much pressed or handled. From the great apparent vascularity of the tumour, Dr. Wagner and his colleagues would not venture upon extirpation by the knife, but it was determined to make shallow incisions on the surface, and then to excite suppuration and the destruction of the whole by strong corrosives. This was done; but the application of the solid nitrate of silver gave rise to severe symptoms of cerebral reaction, and to erysipelatous inflammation. But the treatment was still persevered in for ten months and more, though, in spite of all their efforts, new growths were constantly put forth to supply the place of those that had been destroyed by the butter of antimony, and other caustic applications. About the beginning of April, ten months after the patient had first entered the hospital, a great increase of the constitutional symptoms took place, and masses resembling cerebral substance came away from the profusely suppurating surface. On the 10th, the patient was seized with violent general convulsions, which soon ceased; but there remained complete paralysis of the left side of the body. These convulsive attacks frequently returned, until the death of the patient on the 2d of May. The examination was commenced within five hours after dissolution. The right anterior lobe of the brain was found to have constituted the tumour observed externally during life;

a prolongation of its substance, to the extent of five inches in length and an inch and a half in diameter, passed out through the right orbital foramen into the face, having destroyed a portion of the frontal, the nasal, and ethmoid bones, to form a canal for its exit. The membranes of the brain exhibited a high state of inflammation.

NOTICES TO CORRESPONDENTS.

☞ *Subscribers who are in arrear since Midsummer, are requested obligingly to forward their remittances. By paying in advance for the year, a saving is effected to them, and much trouble about accounts spared to us. Our rule is to be paid in advance.*

A. M.—*We can give an Irish apothecary but small encouragement in reference to English assistantships. Already we have far more than can be decently placed.*

M.D., *who has sent us some suggestions of apparent importance, will oblige us by developing his views more at large. The step he advises is so important that the data on which he grounds his opinions should be very certain and conclusive.*

Dr. Jacobs' *letter is surely unworthy of the position he enjoys in Ireland, both as a gentleman and a man of science. To speak of one of our correspondents, whose name is unknown to him, as a "despicable individual," whom he "regards with* contempt;"—*to apply off-handedly the word "baseness" to his* "motives," *of which he can know equally little, and finally to hint, however obscurely, that we have held up Dr. J. to reprobation for "offered inducements," is to shew, not that Dr. Jacobs is better than he is thought, but quite another thing, viz., with what a smal amount of knowledge or truth Dr. Jacobs can constitute himself the accuser of men a thousandfold* more *we had almost said, but at least* as *conscientious and honourable—especially if this letter be taken as evidence—as himself. No correspondent has made in our columns any strictures on Dr. Jacobs as a* public *officer, who did not previously communicate to us his name as the test of his sincerity and worth, and if Dr. Jacobs felt that his merits, rich or poor, were misapprehended, he well knew that our columns were freely open to his explanation. Dr. Jacobs makes a great mistake if he supposes that he has in any way aroused a personal ill-feeling in our minds; much more if he fancy that he is too important a personage for us to afford to do him justice. There is not one of the million persons of whom we know nothing, about whom we are more indifferent. The critic Dennis, who was in daily fear that Louis the Fourteenth, to avenge a libel, might land an army in England for the critic's special arrest, was almost the type of Dr. Jacobs in his foolish fancies of the extensive antipathies of the* Medical Times. *A copy of Dr. J.'s note shall be sent, as desired, to our correspondent.*

Communications have been received from Mr. Allan of Epsom, and Mr. Thompson of Ripon.

We regret to be obliged to postpone a mass of correspondence till next week.

THE MEDICAL TIMES.

SATURDAY, JULY 26TH, 1843.

Fortem posce animum, et mortis terrore carentem,
Qui spatium vitæ extremum inter munera ponat
Naturæ, qui ferre queat quoscunque dolores,
Nesciat, irasci, cupiat nihil, &c.—JUVENAL.

THE session will almost inevitably close without anything being *done* in the House for Medical Reform. Sir James Graham will, in a day or two, probably re-introduce his Bill, and make that explanatory statement which is to serve, we fear, rather as the *elegy* of the Minister's past Medical labours, than the *genesis* of a successful Bill in the future. Yet we look forward with no discouragement, backward with no regret. The Profession never stood in a more promising condition than now. The great fact that meets the eye is that there is but one party among almost 30,000 practitioners, and that that party is influenced by one mind, and allows all its energies to be wielded directly or indirectly by a Council of its own choice. In the COMMITTEE of the National Association the Profession finds its Executive. Everything rests on that Committee! With a clear and sagacious view of an improved medical polity—with a fixed and, we are able to say, an *enthusiastic* resolve to exert every atom of their power to develop and encourage to the utmost all that is high and able in the Profession, they cannot continue in the high position in which the Profession has placed them without accomplishing that revolution in Medical government towards which every thoughtful mind wishing well to the progress of science is yearning. Perhaps the real matter for congratulation is, that Sir James Graham has been practically coerced by corporate influence to deny the Profession's Committee the limited concessions he had prepared for them. The new negotiating party had scarcely time to acquire the full sense of its own potency, and must have felt an almost irresistible tendency to compromise much that it had a right to, to secure the conquests that can no longer be denied it. To use Sir James Graham's words on another occasion, they were likely, by their position, to be urged to the very utmost "verge" of good-humoured concession. They were, in truth, in an obliging temper by feeling, an humble one by novelty of place, and by habit, interest, and love of peace (by every sort of circumstance, in fact) in that accommodating humour when, for an amicable solution of the problem of Medical Reform, they would have made the utmost sacrifice compatible with the retention of honour. The Corporations, in resisting too much, have let the favourable moment pass by, and their next negotiations will find the yielding party of this session the stubborn and exacting party of the next, with demands higher and more clearly defined, and from which no Corporation, no Minister, nothing but the universal voice of the Profession shall make them abate one jot. This, to us, in the review of the session, is matter for congratulation only second to the success of a good Bill itself, just as carefully and wisely to organise victory is the next thing to secure it.

From the College of Surgeons we have no *fears* for the future movement, and we have long ceased to nurture *hopes*. The Council know nothing of the age in which they *now* live. The progression of Medicine has been far more rapid than they have been able to allow for. They cannot keep up with the feeling of their brethren. They cannot be taught that the period for fostering, under the *name* of Colleges, dining clubs and sinecure emoluments for themselves and friends, professedly on behalf of *science*, has gone by; or, if they begin to fancy such "pretty things" a little shakey, imagine that a nominal concession—a greater or less partition of their future spoils—will set all to rights. Mistaken persons! When they find a National Faculty of Medicine springing up as by magic, and graced with all that is really illustrious in the Profession, and their own Institution a bankrupt and ruined pile, then will they awaken to the extent of their blindness!

We mistake the Profession vastly indeed, if any lures from that body of incapables, or any miserable attempts at dissension outside, will interfere with that imposing attitude which their union and mutual confidence now give them, or impair that confederated potency, which, continued, is the sure earnest of a complete and happy change in the affairs of Medicine.

Quanti emptæ? parvo. Quanti ergo? octo assibus. Eheu.
HORACE.
What doth it cost? Not much, upon my word.
How much, pray? Why, two-pence. Two-pence, O Lord!
CREECH.

——— Quis talia fando,
Temperet a lachrymis?—VIRGIL.

To call the Medical Profession "degraded" is to apply to it one of its most common and, in some respects, deserved epithets.

'Tis true, 'tis pity, and pity 'tis, 'tis true.

The stigma, however, is less applicable to the Profession on the continent than in England—the more their honour, and our shame! Abroad it has a fair chance in the great race for emolument and fame—at home it is disputed and denied the privilege of creditable competition. There, title and emolument are equally within its grasp—here, it is esteemed, and even made, inaccessible to either. Comprehending in its essence and import the accumulation of the loftiest of human knowledge, and the dispensation of the choicest of human good—a vehicle of heaven's bounty, and an opportunity of man's gratitude—it merits in itself little less than the divine honours which antiquity was pleased to award it. In their keeping, unchristianised though they were, it was a solemn means and a sacred emblem; respect was had to the purposes of its fulfilment, and its duty was, in some measure, the hand-maid of devotion. Far otherwise is it now. The fane is desecrated—corruption has despoiled it—the fair proportions have sunk into deformity, and what was once purity and strength, has become degeneracy and weakness.

Heu, quantum mutatus ab illo Hectore!

For this degradation, however, the Profession is, in a great measure, its own debtor. Had it paid to itself the respect due to its intrinsic importance, it would have exacted, in some sort, a worthy measure of respect from the world at large. Failing in this, society has taken advantage of its impoverishment, and has burdened it with humility, instead of blessing it with honour. The evil has increased until it has acquired a consequence little short of criminal, and now the members of this ancient and learned community are respected and recompensed like the veriest hirelings of drudgery. They are openly advertised for as common marketable commodities, and are offered the benefit and bounty of serfdom The instances of this insult are of constant occurrence, and seem daily to be growing in their grievance. As a type of the whole, and certainly, as a climax of most of them, we refer to an advertisement which has appeared upon the covers of our own Journal, and upon those of some of our contemporaries. Our *public* duty gave sanction to its insertion, but a sense of *professional* duty prompts us to expose and repudiate the contemptible conditions of its offer. The advertisement was for a "*professional* man of *gentlemanly* and cheerful man-

ners, and *good education*, to take care of a nervous invalid." He would be expected to "*shave and dress* his patient," to "join him at meals," and accompany him in his walking and riding exercise. For these several "light duties" the poor hireling was promised to be "*treated like a gentleman*," and to have a bonus of *fifty pounds a-year!* As the Kentuckian said, this is the "most tarnation staggerer" we have met with for many a-day. If it be come to this, "throw physic to the dogs," and "cry havoc" in all schools and colleges, say we. This premium-impoverishment was last week commented upon by a "Constant Reader," who wittily observed upon the disadvantages of abolishing barber-surgery. We are precisely of our author's opinion, for though it would be a maximum degradation for a surgeon to take upon himself the duties of a barber, it was the highest honour, in days gone by, for the latter to dabble in the mechanical delicacies of surgery; and they only want inviting to become the same reputable men as aforetime they were. Why did not the advertiser solicit the services of a knight of the shaving-brush at once, and say that he must hold himself responsible for the performance of sundry chirurgical arts? Such an announcement would have carried some weight with it, and no doubt plenty of *professional gentlemen* would have been found ready and willing to do the artistical and attentive, in all agreeableness and good humour. Every requisite, from a newsmonger to a nerve-doctor, would have been found centered in a single individual, had he been applied for in the right quarter. Possibly, a man might have been hit upon who would work in such magic combination the double duties, as to defy you to say which of the two had the preference. He is dead now, poor fellow, or else a "cracksman," of whom the following epigram was written, significant of his aptitude for *cutting his customers*, would have been just the man, and cheap at the bargain, to serve the purposes of the advertiser.

> Barbers in days of yore, we find,
> Shaving and surgery combin'd;
> Lancet or razor, at their will,
> They us'd alike with equal skill;
> But you surpass them far, my friend—
> Both trades you dexterously blend;
> And for a single penny, you
> Shave customers and bleed them too.

Fifty pounds a-year and *gentlemanly treatment* to a *professional man, well educated*, who will be expected to *shave* and *dress* his patient! Perhaps he would also be required to mend his patient's stockings and make his patient's clothes; to be *modo vir, modo fæmina*, now a man, now a woman—an *epicene*, or what you will. We are not told whether he would have to cut his patient's corns, and pick his patient's teeth and ears; but most likely he would, and we should be far from considering this extra "light duty" either an imposition or a degradation; on the contrary, we should say that there was something classical in it, for we find Tryphon, the barber, in "Herod and Antipater," speaking as affectionately of the instruments sacred to these operations as of any in his service—

> Toothpick, dear toothpick; earpick, both of you
> Have been my sweet companions.

There could be no objection, therefore, to the *professional superintendent*, when not otherwise engaged, attending to these little decencies. He would be expected, "so says the bond," to take his meals with his patient, which we apprehend to mean neither more nor less than having to tie the patient's bib and fill the patient's mouth before pretending to put a trifle into his own. In so far the duty would certainly be light. Also, he would have to accompany his patient in his walks and rides. Judging from what has gone before, we take it that his peregrinations would chiefly consist in his being his patient's walking-stick at one time, and his carriage horse, in a Bath chair, at another. There would be nothing amiss in this exercise, because it would breathe the doctor well, and give him plenty of fresh air, both of which we know to be very conducive to health. When the advertiser was about it, he might as well have suggested that if the professional attendant, along with the duties of a barber, could also couple those of a joiner and cabinet-maker, the extra accomplishment would render him additionally useful; and so it would, for he might then employ his leisure hours in making rocking horses and easy chairs for his charge. Considering the liberal salary and the "light duties," it strikes us as being an oversight not to insist upon further qualifications on the part of candidates. It would have probably brought more into the field, and multiplied the chances of favourable selection. We remember in familiar rhyme a distinguished name that would have done honour to the situation advertised, had its illustrious possessor been fortunate enough to have become the "chosen-one." His acquirements were numerous, and precisely to the point, as is testified when he says—

> "What with shaving and tooth-drawing,
> Bleeding, cabbaging, and sawing,
> Dickey Gossip, Dickey Gossip is your man,
> Match him if you can,
> Dickey Gossip, Dickey Gossip is your man!"

In our opinion, he would have been, of all men, *the* man to discharge the "light" and "gentlemanly" duties, and to pocket the premium and affront together.

But we must part with pleasantry now, and view the matter in a more serious light. We regret to have to do so, for we love a joke when it is harmless—*castigare ridendo mores* is the happiest mode of correction we know of, and we always adopt it when practicable. But in some cases it does not suffice singly, and the present is one of them. There is fun enough in the matter, *de se*, and we have really enjoyed it, but as most questions, like Janus, have two faces, we find that this also presents an aspect the reverse of mirthful. In itself it is nothing, but, as we have said, it is in some sort a type of an existing state of things, which is compromising the best interests of the profession. In what esteem must medico-chirurgy be held, when one of its "well educated" and "gentlemanly" disciples is advertised for, to take charge of a patient, and shave and dress him? Must not its disciples be considered little better, and no more deserving, than barbers and valets? Fifty pounds a year as the premium of intellectual prostitution! The wages of a decent footman, and a *salary* that a journeyman shoemaker would turn up his nose at! Is such a thing to be found in the world's history, as a lawyer, or a parson, or even a pedagogue, being required to shave his client, his parishioner, or his pupil? And why is the indignity levelled alone at physic? Simply because its visitation has been invited. The profession has forgotten the respect due to itself, and the world has rewarded it with a solicited insult. Is there anything in the preparatory study, and in the examination, to qualify a man to practice law, or preach the gospel, which gives to such man an intellectual or a worldly dignity above a physician or a surgeon? We deny that the pursuits of legal or clerical studentship are anything so various and comprehensive as those which are imposed upon the medical student; and we also deny that the examination for the pulpit or the law bears any comparison with that for physic and surgery. At least, then, both in the compass and the cost of study, the medical practitioner is quite on a level with members of other professions, and in his state in life, is a man of as much personal consequence. But here the relationship ends. The clergyman, or the lawyer, remembers the dignity of his calling, in all his dealings with the world, from which he never fails to exact the deference which is his due. When he serves society, it is to serve himself, and he is never prodigal of gratuitous labour. You neither find the one opening his house and his wisdom on certain days to all penniless comers, nor the other administering "even a cup of cold water," without "fee or reward," to the dying inmate of a hospital or a workhouse. Each knows that as a labourer he is "worthy of his hire," and, as becomes a man of the world, he makes professional service synonymous with payment; and so the world esteems him, and sets full value upon what he does for it. It is the opposite of these things which has degraded the medical man. He is ready with his advice for everybody, whether it be asked of him or not, and he squanders it with a profusion which suggests a belief that it is valueless. He serves public institutions for nothing, and private individuals also, if they ask his gratuity. Nay, rather than not be "up and doing," he will, upon the same terms, run any distance after patients, if they do not choose to run after him. In committing these follies, he lessens both his personal consequence and his income; for, whilst his services are esteemed insignificant, being *given away*, yet are there plenty who will receive them as *priceless*. But, whilst he affects this charity to those who *will not pay*, he is willing to be, to any amount, a stipendiary upon those who *will*. Herein consists his chief discredit. If he cannot get a legitimate fee, he will take its lowest representative. Hence has arisen the pauperising system of club attendance, the penny fee trap, and the other abominations which degrade and ruin the profession. Not the public only, but actually the legislature, has taken advantage of this servility and weakness, and they give to a union, or a parish surgeon, a stipend that will barely keep his horse. They look upon him as a mere drudge, and pay him the wages of a menial. There is something humiliating enough in being required to *shave* a patient, but this degrading office is scarcely more contemptible than doing the dirty work of clubs and parishes at such emoluments as are accepted by members of a learned profession. If we did not give the world to believe that we are corrupted and corruptible, it would not dare to throw the temptation to disgrace in our way. If we did ourselves more justice, society would be glad to contribute to the homage. If the evil is to be remedied—and God speed it—the reformation must begin amongst us, and with that class especially (alas! how numerous) who teach the world to believe that the duties and the pay of a medical practitioner are those of a servant of all work.

LETTER FROM DR. C. J. B. WILLIAMS.

We should have inserted the letter below last week, except for a charitable feeling, that a tolerable interval of time might suffice to give the writer that second, and better thought, which must have followed the first exercise of reflection. The result is other.

To the Editor of the Medical Times.

Sir,—As I find that many persons are under the impression that the reports of my lectures on the Practice of Medicine, which have for some time past appeared in your Journal are authorised by me, I think it due to myself publicly to state that they are not so,

I believe that they were taken by a short-hand writer who is ignorant of medicine and medical terms; and if they have been corrected at all, it has not been by myself, nor (except some of the early lectures), so far as I know, by any of my pupils.

I trust that you will publish this statement to account for numerous errors and omissions, which in many parts of these reports are such as to destroy or wholly pervert the sense; and for which it is not fair that I should be supposed to be responsible.

I am, Sir,
Your obedient servant,
C. J. B. Williams.

Our correspondent seems angry because it is supposed that he (Dr. W.) gave any "authority" to the publication of his lectures. We may possibly not form the same favourable estimate of the importance of his "authority" as the writer, who is understood to be well up in this part of science; and hence, perhaps, has it arisen that we have felt pleased to announce—as more than once or twice we have distinctly announced—that the lectures, after revision by a medical man, came to us through a short-hand writer. All we claimed was to have published them (with the amendments they necessitated under a medical revision) as Dr. W. delivered them to his class. So much for our thought of his "*authority?*"

But suppose, after all, the "authority," important or unimportant, *was* given, how, then, will our correspondent stand? And we ask him, was not a small portion of the course furnished us, to his own knowlege and privity, by a very distinguished pupil of his? Did he not *give* with his own hand *a ticket of admission* to the lecture-room to our reporter, for the special purpose of taking the rest of the course for us? And did he not, for seventy or eighty successive mornings, retail his lectures with the daily understanding, that they were being stenographed for our publication? Nay, that some of them then were undergoing publication? These are plain facts; things that have no nonsense, nor sham, nor pretence in them; no winding, nor hiding, nor artifice—neither a *suppressio veri* nor *suggestio falsi;* and they do make us wonder how Dr. C. J. B. Williams, F.R.S., can come before the public, giving some rude guesses as to the supposed way the lectures were procured, and generally disclaiming his "authority" (much more his facilitating aid) for their publication. Dr. W., no doubt, fancies he adheres strictly to his creed of veracity. With that we have nothing, or *will* have nothing, to do.

The reporter is incontestably one of the best *verbatim* short-hand writers of the day, and is employed in the most important *legal* cases, in which his really wonderful fidelity is relied on where property has been in question to the amount of hundreds of thousands; and where, without the most rigorous accuracy, his presumption would be ridiculous. Though, in literal reporting, as in the present case, a knowledge of the speaker's technical terms is anything but indispensable, he really has a large acquaintance with the medical vocabulary. He has reported at least three full courses of medical lectures—one on forensic medicine, for a legal journal of high standing, to which his reports added great credit; and we should not be ever the mark in saying that he has stenographed at least a dozen courses of lectures, all enjoying high repute as verbatim reports. Such was the reporter. To make surety doubly sure, however, each lecture, before publication, was submitted to the careful revision of a medical gentleman for years past in close connexion with all our medical literature. That under this revision the lectures underwent changes, we do not deny; but when we mention that there was scarcely a lecture without a multitude of repetitions of the same sentence, that no *additions* or interpolations in *matter* were *ever* allowed by us to be made to them, and finally, that they were delivered extemporaneously *and* by Dr. W., we think we may claim with confidence that the suppressions in some cases, and changes of literary style in others, were not made to the lecturer's injury. Some slight auditory mistakes may, of course, have occurred to the reporter, however perfect; some oversights, possibly, to the medical gentleman revising, however attentive; and typographical errors in a weekly work are things almost impossible to avoid. The reported—and the reported-for—know all these things, and we are the last to deny them, though to the benefit of a somewhat unkindly correspondent. But as a general *report* of the course we pledge ourselves to its accuracy. If Dr. W. at last would disown them himself, he avows his plight as a lecturer to be bad, indeed.

Of the profound, Graves-like qualities of the lectures we shall be silent: if they do not interest, the only consolation that remains for our readers and ourselves is, that involved in them by a supposition that fame was desert, three more numbers will rid us of them for ever! We have been dispatching them, as our readers have noticed, with all the quick, quiet celerity we could command, and when the conclusion does come, we shall feel as if the *Medical Times* were relieved from a night mare.

BOOKS RECEIVED.

A System of Surgery. By J. M. Chelius. Translated from the German, and accompanied with additional Notes and Observations, by John F. South, Surgeon to St. Thomas's Hospital. Parts 1, 2, 3, and 4. Renshaw.

In the German language this work has already run through six editions; in the English it will not reach less. Chelius brings a master mind to his work, and where at fault—as the best sometimes will be—Mr. South's notes come admirably to the rescue. The work is to be concluded in twelve parts, the four first of which have appeared with that rigid punctuality, which is at once so laudable to publisher and author, and so necessary now-a-days to win confidence from purchasers. We postpone Chelius, however, for a moment when we can with more extended data before us, give a more detailed notice.

The Elements of Morality, including Polity. By William Whewell, D.D., Master of Trinity College. 2 vols. Parker.

The celebrated author gives us here a clever book, pervaded by much brilliancy of error. He thinks moral philosophy can be founded on axioms, about as certain as those of physical science; and that we can proceed from one dogma of natural religion to another, *ad infinitum*, with all the certitude of geometric demonstration. He has some moral elements equivalent to axioms, viz.:—Humanity, Justice, Truth, Purity, Order, Earnestness, and Moral Ends, which appear to us, in great part, so far THE *natural* moral principles of man's nature, that they are rarely or never, or not prominently found in him, except under a high state of social teaching! Destruction is as much a natural principle as humanity, and where nature, as opposed to civilisation reigns most unpruned, where, in other words, the animal tendencies of *nature* are more indulged than the rational tendencies, there is precisely the region where the "inherent principle of good"—the "moral axiom" of nature is *not*. There really is no *human rule* of right and wrong, and its opposite is found. The only human one that can be by courtesy termed a *rule*, is that which general assent adopts, varying with every stage of civilisation, and with the qualities of the civilisation in each stage; differing in the same country in different centuries, and in the same century in different countries. It is absurd to suppose that differently organised tendencies of mind and body, acting under varied circumstances, should hit separately and of themselves on the same precise idea as the elements of a code of right. What would be right to one, would be as wrong to another.

A Dictionary of Terms employed by the French in Anatomy, Physiology, Pathology, Practical Medicine, Surgery, Midwifery, Pharmacy, Medical Zoology, Botany, and Chemistry, with their Derivations. In 2 Parts. Part II. A German-English-French Dictionary, comprehending the Scientific German Terms of the preceding Part. By Shirley Palmer, M.D., of Tamworth and Birmingham. London, 1845.

The profession will be rejoiced to learn that this work has at length been brought to a fortunate close. Considering either the judicious labour that must have been spent in its compilation—and it must have been gigantic—or the vast utility it must subserve to every inquiring mind in the profession, and that utility will be enormous, we are justified in considering Dr. Palmer's work as one of the greatest biblical boons for which medicine has, of late years, been indebted. Lexicography in our science is a vast want, which offers few temptations for supply. The toil reacts more than a Johnson so elaborately expatiated on in his celebrated preface, and the repayment either in fame or money is at least 99 per cent. less. We trust the profession, after our example, will do their "possible" to amend the state of things, and remunerate our author for the daring industry which, under such discouraging circumstances, he has placed at their service.

The complaint has been made that the French is made the leading language. But it would appear that the whole work sprung out of a design to meet the wants of students reading French and German literature; and considering, indeed, that it is during the perusal of foreign works that the reader is most likely to need Dr. Palmer's assistance, we think our author has done well to take the plan which, if it convey no idle national complaint, performs a very important national service. It may be added, too, that the work now, by a German appendix, is equally serviceable to readers in that language, and that the author proposes a supplement (very desirable by the way), in which he will furnish vocabularies, to meet the want of readers in the other languages, viz.:—English, Latin, and Italian.

WARNING AGAINST FALSE CAPERS.

(To the Editor of the "Medical Times")

Perhaps a short statement of the following case may not be thought unworthy of a corner in your publication, as exhibiting the violent effects sometimes produced in weak subjects by plants of the genus euphorbia. On Tuesday last two male children, of the ages of six and four, were seized with violent vomiting and purging when about to commence their dinner. Their mother, hearing that they had eaten some kind of seeds found in a field, sent for me. When I arrived, the elder child had recovered; but the younger, besides being sick and faint, had a very dilated, almost insensible pupil; pallid countenance; weak, unsteady pulse; and some degree of derangement of the senses. It appeared that this child had eaten by far the greatest number of the seeds. The pods were shown me, and I pronounced them to be those of euphorbia lathyris, or caper spurge. The matter vomited did not lead me to suppose that any portion of the seeds remained in the stomach; I did not, therefore, give an emetic; but administered, to each child, an active purgative; and to the younger, moderate doses of sal volatile, every hour, with tincture of cardamoms. About five o'clock, a boy of two years was seized with vomiting, from the same causes; but his symptoms were very mild, compared with those of the second boy. Before night came the symptoms had disappeared in all, and they were, this morning, quiet well. It appears to be a common practice to pickle these seeds, as the *true* caper; but we do not then hear of their

ill effects; no doubt, the acrid juices are much weakened by solution in vinegar. As this is the first instance I have met with in which they have been *proved* to do mischief, I thought a short record of the case might not be unacceptable to the profession at large.

WILLIAM ILOTT, Surgeon,

Bromley, Kent,
July, 23rd, 1845.

THE UNIVERSITY OF EDINBURGH AS A MEDICAL SCHOOL IN 1845.

To the Editor of the "Medical Times."

SIR,—There is scarcely any subject that can be discussed in a medical publication, more vitally important to the public, than that of the merits of medical schools, and there never was an epoch, in the history of our profession, when it could be more appropriately done, than at the present moment. It was with pleasure, therefore, that, in casting my eye over the table of contents of the last number of the *Medical Times*, I perceived the announcement, "The University of Edinburgh as a Medical School;" but surprised was I, indeed, at the sentiments of the writer of the article to which I refer, to say nothing of the spirit in which his remarks, generally, and his criticism of Professor Traill's translation of Schlegel's Essay on the Physiognomy of Serpents, are endited—

"Wit dwells not oft with wisdom, and, I fear,
'Tis possible to buy a joke too dear."

as said by Bishop Tenot. But, be that as it may you will, I doubt not, on the *partem alteram audi* principle allow me to reply to your correspondent, which I shall do in a temper befitting the occasion, and consistent with the important interests involved in the controversy, for such it must be, in consequence of the position assumed by the writer, against the sentiments and insinuations of whom I protest, and appeal to the judgment of the candid and enlightened readers of the *Medical Times*. Of you, Sir, I respectfully ask a fair field, and no favour; *that*, I am convinced, you will readily grant. I have the honour to be, &c.,

ROBERT LEWINS.

Tiverton, July 21, 1845.

REMARKS ON MEDICAL EDUCATION.

By ROBERT LEWINS, M.D., &c. &c.

"Now, Truth perform thine office; waft aside
The curtain drawn by prejudice."

The *Medical Times* of Saturday last contains an article headed, "The University of Edinburgh as a Medical School in 1845." "It seems," says the writer, "to be a fact pretty clearly admitted, that the Premier has taken up a strong *predilection* for the system of the present Scotch colleges, or, at least, for a modification of them, and that he intends giving to this system, be it good, or be it bad, the whole weight of his power. Nay, what is more, it is said that he intends extending the system to Ireland, and ultimately to England." "Thinking men might be disposed to say—had you not better first ascertain how the system has worked? how educational institutions have thriven, where the pedagogue and teacher occupied the position of the professor? Have any of them sunk to mere diploma shops not over respectable? Have men of genius and European reputation found a ready access to the chairs?"

Tried by these tests, I hesitate not to assert, and fear no contradiction from any candid man conversant with the facts of the case, that a "predilection" founded on a knowledge of the effects produced by the system long ago adopted, and still rigorously acted on by the medical faculty of the University of Edinburgh, is theoretically accurate, and, practically, will be found to realise the rational expectations of the Premier, and of every other intelligent man.

But let us appeal to facts bearing directly on the sentiments of the author of the communication on "The University of Edinburgh as a Medical School in 1845," manifested by his not over-courteous queries; and first, as to the appointment of professors, a proceeding to which his attention has evidently been particularly directed, and with which the doings of the patrons of the chairs have obviously not satisfied him. *Naso suspendere adunco* is an insult to which I imagine he supposes he has been subjected. I might reply to the sarcastic author's first query in one word, *circumspice*, in reference to those who *were* professors in the course of the last hundred years, and who *are* so at this moment. It were absurd in this place to advert to the works of the medical luminaries who have shed a lustre on medical science, and done honour to the chairs of the University of Edinburgh, since to the readers of the *Medical Times* the names of Whytt, Cullen, Munro, Black, Gregory, Duncan, Hamilton, Bell, &c., must be familiar as household words.

I proceed to respond to the second query. In the ordinary sense of the word, there is no one who fairly deserves the name of pedagogue in the University of Edinburgh; that a professor's attainments as a *teacher* should be considered objectionable is a new, and, to me, an extraordinary idea. I have, on the contrary, been accustomed to think that estimable men of first-rate genius have frequently failed as professors for want of the peculiar talent of imparting knowledge.

The appropriate answer to the third query is, that the medical diploma of the University of Edinburgh *has been* and *is* held in high and deserved estimation by all competent and impartial judges of medical testimonials. Have men of genius and European reputation found a ready access to the chairs, in bitterness of spirit evidently, asks the writer whose production on the medical system of teaching in the northern metropolis I now criticise.

Men of genius—and rarely, indeed, others—*have* found access, although not always a ready one, into the Edinburgh medical chairs, since it has generally happened, when vacancies occurred, that *several* "men of genius and European reputation" have appeared as candidates—keen contests have consequently taken place, rendering the "access" not "ready," but sure, to an unexceptionable, and, almost always, to the best qualified candidate.

The reflection intended to be conveyed by the query under consideration would have been more to the purpose, if it could be insinuated that too ready access was found to the chairs.

But let us advert to the history of the appointments of the present occupants, and to their professional characters as established by their *deeds* as professors—a kind of evidence quite conclusive in regard to the question at issue. Dr. Monro, the professor of anatomy, was placed in his chair when a very young man, and he has now filled it nearly half a century. It is understood that he owed his appointment in a great measure to the brilliant reputation of his father and grandfather, who contributed most materially to establish and extend the fame which Edinburgh has long fairly enjoyed as the first medical school in Europe.

Dr. Monro is, unquestionably, a man of genius, but as a teacher he has not realised the expectations entertained of his career. It is true, as acknowledged by himself, with a degree of candour highly creditable, that his powers as an anatomist and as an author are inferior to those of his progenitors; but it is a fact, nevertheless, consistent with my positive knowledge, that some of the best practical anatomists of the present day, and not a few of the first physicians, likewise, acquired their profound anatomical skill at Edinburgh under the auspices of the present professor, Dr. Monro.

Dr. Graham stands second, in point of seniority, on the list of Edinburgh professors; his chair, that of botany, is a *regius* one. Dr. Graham owed his appointment to his own excellent talents, aided, it is supposed, by the political influence of the late Duke of Montrose; the election proved equally creditable to the patron and professor. Dr. Graham's enemies, if he have any, must admit that he has done honour to his chair, and that he is a popular and successful professor of *clinical* medicine—there are few professors more esteemed and respected by students and professional inferiors, or equals, than Dr. Graham.

In next week's number of the *Medical Times*, I shall resume consideration of this subject as mentioned before—one at all times important to the medical profession, but imperatively more so at this precise period, and under existing circumstances.

To the Editor of the "Medical Times."

SIR,—I was not a little surprised at the strange temper, at the inaccurate statements, and at the sophistical rhetoric of an article accidentally admitted into the last number of your generally impartial and truly liberal periodical. It has been my privilege to be one of your constant readers for some time, and never until last night, on the reading of that article, did I meet with anything that has appeared to me unfair. I therefore conclude that it has fallen into "the tide of the times" by sheer accident; that its types have been huddled together on the plan of the "vestiges of creation," and that it has crept into your little world without either the sanction or the direction of its worthy architect.

I am sure, Mr. Editor, that the article entitled "The University of Edinburgh as a Medical School in 1845" is an *ex-parte* affair. The professors of that university are well known to be scientific men, and the clinical staff of the infirmary comprises as able men as any in the empire. Indeed, what is there in the locality of Edinburgh or Glasgow to make their scientific men inferior? Is not the Scot as quick to observe and remember—as penetrating to arrange and correlate—as judicious to decide—as energetic to act as any man? Are the people that gave birth to Watt and to Hunter incapable of acquiring and of teaching the sciences? Is the preliminary education of the Scot inferior? Is a course of logic, metaphysics, and mathematics, with classical study, compared with the Englishman's exclusively classical study at a grammar school, inferior as discipline to the mind in preparing it for the art of observation, and for a mastership of the difficulties of science? Are not anatomical inspections the same there as here? and is not the nature of disease there as here, cognisable by observation and reflection? These and other points would be very satisfactory bases for an explanation of what your correspondent strives to prove, that medicine cannot be studied in Scotland, as though science were limited to the odour of his own anatomical room. I had certainly thought, Mr. Editor, that although such exclusivism is the natural feeling of some minds, yet that men of genius and education were too well aware of the amount of knowledge current in medical science to allude to such ideas, still more to pretend to elucidate them, by the caricature of a review, by which they are followed. If we are to judge of men by their works, we must remember *that* review did not emanate from Dr. Traill, but from an enemy to Dr. Traill, and, strange in a scientific age, an enemy to a university!

The Scottish system of medical education is not, I will admit, superior to the English, because the two methods are much the same in nature and in extent, the English licensing bodies having, by the gradual substitution of hospital and lecture study for the more degrading period of an apprenticeship, gradually approximated to the method recommended by the Scottish universities. It is only this imitation that has extended the course of study in the English schools, and so made them what they are. I presume all thoroughly educated medical men who are able to practise, are also able to teach medicine, provided musea and apparatus, plates, dissecting rooms, hospitals, &c., are accessible; and I believe the reason that led to the celebrity of Glasgow and Edinburgh as medical schools was the obligation they imposed formerly of at least three years, and for the last twenty years of at least four years, on all who wished to prove their claims to an examination for degrees; whilst at the same æra a six months' course was the curriculum of the general practitioner in studying for the diploma of the licensing bodies of London. The consequence would generally be, superior proficiency on the part of the pupil who had gone through the longest course of study, and a proportionate meed of praise to the alma mater that had fostered and trained his mind to usefulness. This disparity has been done away with for the last few years, in consequence of the increase of study demanded by the licensing bodies in London, and the consequence is that the student from London and the student from Edinburgh having to go through about the same course of study, the value of these, and of most other medical schools, will be sustained by pupils in every sense equal to each other. If the Scottish curricu-

lum should be abbreviated, those schools would soon lose their reputation. To degrade an equal because he was once a superior is, to say the least of it, premature; it is most certainly ungenerous, and at the same time impracticable. The Scottish universities, and they alone can injure themselves —for what was a few days ago well said in Mr. Healey's defence in reference to an *individual* may as truly be said of corporate bodies—" no man can injure another's character but himself;" and as long as those universities exact a long course of study and a fair examination—as long as they possess such men as Christison, Ballingall, Lizars, and Syme of Edinburgh, Burns and Thomson of Glasgow, all men of European reputation—and as long as they send out some of the ablest practitioners in the empire, so long will no correspondent be able to write them down.

The misfortunes assigned to these institutions are two-fold: 1st. They are diploma shops; this I deny—diplomas are not sold at any of the Scotch universities; and are obtained only after a definite course of study, and an examination, the stringency of which is attested by the number of refusals; then, again, " when Gottingen is mentioned, we think of Haller; when Leyden, of Albinus." How fertile in great men must such places have been, when we have to go back 70 years to read of the death of one, and 100 years to record the conclusion of the career of another! Your correspondent might have had the honourable feeling to have remembered that contemporaneous with Haller, " there were giants in those days" educated in Glasgow and in Edinburgh, who, great as Haller was, were greater—the Hunters, William and John, the counterparts in the healing art, of Lord Bacon in the art of reasoning—men, precisely of whom it may be said as a parallel to your correspondent's statement, " when surgery is mentioned we think of Hunter."

I cannot help naming what seems to be another objection—" two general practitioners occupy the chairs of surgery." This remark shows that your correspondent knows nothing of Scotland, and therefore has no right to judge the question: all the medical men there, with very few exceptions, practise medicine, or the healing art in all its branches; one does not attend a woman in her accouchement, another bleed her, and another prescribe a diaphoretic, three gentlemen at once, like another Cerberus, to perplex and torment. The bearing of this error, however, comes to this, that such men as Burns, of Glasgow, and Syme, of Edinburgh, are not able to teach surgery."

The last crying evil is, that Scotchmen are, like other people, partial to their nation, families, and to their friends. Does not local influence chiefly settle an election at Guy's and St. Thomas's, at St. Bartholomews, at our own universities—every where—limited only by this principle, that the men elected shall be capable, in the fullest sense, to perform the duties of their respective offices? Local influence will undoubtedly in Scotland, as it does elsewhere, place men in eminent stations; who that knows any thing personally of their professors will pronounce any of them unworthy?

Taking this subject, Mr. Editor, in its most favourable light, I must think that " Homer has once nodded"—that you have for once been incautious in admitting an article loose in its veracity, inaccurate in every sense, and alien from the truly catholic feeling with which you usually regard the science of every land. If it was written seriously, it can claim paternity from only one class of persons, the proprietors of some London " diploma shop"—of some anatomical back settlement, who might imagine that an indiscriminate attack on the Scotch universities might lead some raw youth to " pull the other way," and stray by chance into their own portals.

I shall be happy to see this letter, or some other on this subject, inserted in your next number, so that the stain may be effaced which such misstatements are calculated to leave on the unsullied and honourable character of the *Medical Times*, and that the charge may be removed from myself, and I am sure from many of your readers, of believing such puerilities.

I am Sir, yours very truly,
J. DEANE.

Chatteris, July 19th, 1845.

[The article here criticised was sent by a gentleman of eminent scientific attainments, who communicated to us his name.—Ed.]

GRATUITOUS PROFESSIONAL SERVICES.

(To the Editor of the Medical Times.)

Sir,—In a recent number of your periodical, I read a statement that the registrar-general intended to make every licensed medical practitioner a present of a case-book, in which might be recorded, under certain heads, the history of each case treated in his practice. The object of this is to facilitate the registration of births and deaths, so as to render our statistical information on these important points more extensive and correct than it has hitherto been. This would obviously be a great national benefit, and it is highly desirable it should be obtained.

But, Mr. Editor, I want to know *who is to give us our* FEE, *for keeping the registrars' books and for writing out certificates of the causes of death among our patients?* Why should *we*, of all men, be expected to do anything for nothing? Do the clergy, or the shopkeepers, or the artizan, or the " navigator," or does anybody else whatever, *work for nothing?* Are we not sufficiently ground down already by every conceivable injustice? And whom have we to thank for all this?—Truly, *ourselves*; for we have been so eager, in our fatal rivalry, to get a decent living, that our tenders to the public, have been gradually becoming less and less, and the fact is that a man entering the profession, without private means, must make up his mind to attend and furnish medicines, by night and day, for years, not only without adequate remuneration, but absolutely without even thanks. People consider the medical man's time and skill as public property, which everybody can insist upon having, but nobody has any occasion to pay for. Witness the very modest proposal of our friend the registrar-general. Of course he *pays* the under registrars and clerks for their trouble and time in collecting reports, &c. &c., and is *paid* himself for his own labours; but when something is wanted which can only be given by medical men, he considers it quite enough to give *them* a paltry book, to be kept for *his* interest and convenience, *not theirs*; and even seems to think he confers a favour in providing the book, and not compelling the poor creatures to find it out of their own pockets! Not a word about the *fee* for writing out each certificate, and for keeping records of cases!

I do hope, however, Mr. Editor, that the profession will, for this once, insist on being *paid* for their services; to which they are quite as much entitled as the surgeons employed under the New Poor Law, and the Factory Act. Let us calmly, but firmly, refuse to write certificates for any government purpose, unless we are to receive proper remuneration. I have done this, and if it only become general, the event must be, that we shall obtain our just due.

I am, yours respectfully,
GEORGE WILSON,
Surgeon.

3, St. Peter's Square Leeds,
July 21st, 1845.

[There is certainly a small hardship in doing a government service for nothing, albeit done for the public good and under no compulsion. But if Mr. W. reflect on the whole subject, he will find a difficulty on the other side even greater. How could any Government have 30,000 medical men in constant pay as their annual stipendiaries, for a service which should not cost a *successful* practitioner half an hour's toil per annum. We have too many *real* griefs against Government, Assurance Offices &c., to make " *much ado*" about this somewhat *filmy* wrong.—Ed.]

THE MEDICAL TIMES TESTIMONIAL.

Dear Sir,—I beg your acceptance of the accompanying mite (£1 1s.) as a small contribution towards the object you intend to accomplish with the money, which the members of our profession, with their hearts " in the right place," remit to you, as a proof of their approbation of your manly deportment on a late memorable occasion.

You did well, I think, to give a place in your columns to the *Standard's* article on the " Law of Libel." It is, as I said before, one most pertinent to your case; and I may add, specially condemnatory of the notorious personage, who had the matchless assurance to appeal to a jury on such an occasion the " world " seems to appreciate very accurately the position of the " *honourable gentleman.*" (!)

You hit him hard with a quotation from the immortal Scotch poet—what say you to the following from the best moral writer in verse that England ever saw:—

" But let eternal infamy pursue
The wretch to naught but his ambition true:
His aim was mischief, and his zeal pretence,
His speech rebellion against common sense;
A knave, when tried on honesty's plain rule,
And when on that of reason, a mere fool;
The world's best comfort is, his doom is pass'd—
Die when he may, &c."

Cowper.

Yours truly,
Lucius.

July 19, 1845.

[Our respected correspondent seems to form a truer estimation of the public worth of *the* medical representative than even ourselves.—Ed.]

THE SETON CASE.

To the Editor of the " Medical Times."

Sir,—I addressed you a line yesterday on a subject or two, and my attention having been directed to an article in the *Medical Times* of July 5th, written by " An old Army Surgeon," I feel impelled, by a sense of justice towards the three surgeons who had the management of the unfortunate case of the late Mr. Seton, to tell him who and what those gentlemen are.

First, then, of Mr. Jenkins. He is a highly respectable general practitioner of Gosport, in very extensive practice, and of long professional standing.

Secondly, of Mr. Stewart. This gentleman is a navy surgeon, on the retired list, who has been the greater portion of his life employed in actual service. He has been for some time practising as a surgeon at Portsmouth, where, I hear from a friend of mine, an admiral in the service, with whom he has sailed, it is his good fortune to enjoy by far the best practice in the town.

Lastly, of Mr. Mortimer. He was lately the senior surgeon to Haslar Hospital, an appointment which he held for many years. He was universally esteemed by his brother medical officers, and by the public generally, during his long probation at that far-famed institution, and has always been accredited as a man of great surgical experience and judgment.

Without offering any opinion on the propriety of Mr. Liston's treatment of Mr. Seton, or saying a word either in defence or disparagement of the highly respectable gentlemen I have just referred to, I will take upon me to say, that I think the old Army Surgeon should have " doffed his cap of darkness," before he adventured to make such severe strictures on the professional treatment of poor Seton's case by Mr. Liston and his coadjutors.

I have the honour to be, Sir,
(With every apology for this intrusion),
Your very obedient servant,
WILLIAM TUCKER.

Mount Lavington, July 19, 1845.

WAKLEY'S OPINION OF AN OPERATING SURGEON.

Sir,—Much credit is due to you for exciting public attention to the melancholy system of performing unnecessary, and too often, fatal operations; and the lamentable death of Mr. Seton seems to have created a universal horror of the surgeon's

knife. To me it is unaccountable how such practices should still prevail in a civilised country, notwithstanding the efforts that have been made to discountenance operations, of which you gave an interesting example from the works of that eminent surgeon, Mr. John Bell.

Without by any means wishing to detract from the powerful arguments which you have brought forward to throw discredit on those who are base enough to pursue this pure surgical system, it is but justice to state that the enlightened Editor of the Lancet has ably promulgated the same humane principles; and as far back as 1834, when the governors of the University College Hospital were openly and undisguisedly in search of a surgeon who could exhibit like a mountebank in their public theatre, and thus bring a set of young men, for the sake of their pelf, to enter as students at their institution, Mr. Wakley manfully exposed the iniquity of the proceeding in the following powerful, energetic, and impressive language. "Is it true, as reported, that the Council or the Senate, are in search of an operator for this hospital—a mere mechanical cutter—a person who delights in blood? It cannot be; for such has been the progress of medical science within the last few years, that the power of operating is now deemed the most insignificant part of a scientific surgeon's capabilities. Once obtain for this hospital a reputation for its being a cutting and slaughtering establishment, and the directors of it will search in vain for cases of disease wherewith to instruct the students." —(Lancet, 1834-35, vol. 1, p. 73.)

THE APPROACHING ELECTION OF COUNCILLORS AT THE COLLEGE OF SURGEONS.

(To the Editor of the "Medical Times.")

SIR—As the 30th of July, the day appointed for the election of Councillors, approaches, "the plot thickens." Rows and rumours of rows on the day of election are rife among the Fellows. It is even hinted that one *honourable* Member of the Council Board will have the lie direct given him by a fellow Member; and that his blandest expressions and most caressing exclamations of "My dear soul!" "God bless you!" will hardly save him from having the hardest possible names coupled with his. This, perhaps, is the more likely, as from his clumsy intrigues other Members of the Council Board have suffered even more than he has himself, and are of course correspondingly incensed. At all events, report says there will be no want of gentlemen to draw out the secrets of the Board by pertinent questions, scarcely safe to answer, but equally dangerous to allow to go unanswered. These questions, it is said, cannot fail of setting the Council at loggerheads with each other. This possibly may be attended with good effect, for it is an old though somewhat coarse adage to apply to them, that when certain kinds of people fall out, honest men come by their own. It is perhaps a most fortunate thing for these gentlemen that the Council, with a prescience of the exigencies to which they would be reduced truly remarkable, provided by a bye-law that nothing save what is immediately connected with the business of the day shall be allowed, otherwise unpleasant truths might be broached by various of the Fellows who have been cajoled, deceived, and betrayed by their Council. The questions, however, as to whether the Council takes any part in the proceedings by voting or proposing Members, and whether any such resolution was agreed to last year, are clearly within the provisions of the bye-law, and must be answered. I need hardly say that some of the Fellows are more particularly incensed at having been cajoled by the shallow individual above hinted at—a man who has got on in his profession by underselling the General Practitioner, but who has never done anything either to merit the extent of his practice or his seat at the Council Board.

However, my business is not with him, but to warn the Fellows against being again taken in by the flying rumours of the liberal intentions of the Council. Already they begin to fear that they do not stand on quite so firm ground as they once believed, and have these rumours—

"Hinc spargere voces
In vulgum ambiguas."

The barometers of public opinion are anxiously watched and eagerly consulted as they weekly appear. They chuckle, however, in having succeeded so far as to oust all save one of those who were candidates last year. The *eminent gentleman* of the Council pronounces the bye-law, which requires a Fellow once rejected to give a month's notice of his intention to offer himself a second time, whereas the notice of the day of election is given only a fortnight before, "to be a masterstroke of policy;" and which, but for the tenacious memory of Mr Gosset's friends, would have succeeded to their entire satisfaction; for I perceive with much regret that Mr. Gosset is the only one of those rejected last year for whom the required notice, signed by more than six of the Fellows, has been sent in. This is great mismanagement on the part of the Fellows It is an apathy on the part of the friends of Sir Stephen Hammick, Mr. Lloyd, Mr. Macilwain, and Mr. Kingdon hard to be accounted for, since now, unless Mr. Gosset be elected, it for ever shuts out these gentlemen from the honours of the Council

It is, then, of the highest importance that the Fellows should be unanimous in their support of Mr. Gosset. Independently of his own merits and fitness, independently of his high professional acquirements and unsullied integrity (I believe that I can scarcely speak in too high terms of this gentleman, as admitted not only by the Fellows, but even by the Council themselves); for the sake of giving Sir Stephen Hammick, Mr. Lloyd, Mr. Macilwain, and Mr. Kingdon the second chance, which, by their inertness, they have lost this time, and, if passed over, for ever. I say, for the sake of securing these gentlemen a second chance, their friends should exert themselves to the utmost to secure the return of Mr. Gosset.

To return, however, for the second time to the object of my writing; "the flying rumours of the liberal intentions of the Council," published (1) by the "Medical Gazette" of last week. Is it possible that the Fellows can be deceived by one of the weakest, flimsiest, and most common-place contrivances of the day, worthy indeed of the source whence it had its origin? Is it possible that the Fellows will place any reliance on what is so obviously a bait to mitigate their hostility? Can we get honesty out of corruption, truth out of falsehood? This is strong language, I admit it; but I appeal to you, Sir—I appeal to the profession, deceived and betrayed as they have been—to the Fellows deceived and betrayed as they were last year, and as they will be again this, unless they are "up and doing,"—whether it is stronger than the justice of the case imperatively demands, should be used.

If the Fellows want any further confirmation of the idleness of this rumour, let them for a moment think on the instability of the Council's resolves, and of those who are interested in their snug little hospital concern, known to the uninitiated as the "Medical Gazette." Know they not that it is held by a clique of Surgeons and Physicians belonging to a hospital not a hundred miles from the Borough? Know they not that the Council of the College are ASSISTED by one belonging to this hospital, and, I can't say, assisted by another, for he is no *assistant*, and seldom troubles them with his presence? Know they not that it is a colleague of these same who is the protégé of the Council, and for whose election they are moving heaven and earth? Not only canvassing as I said in my last, but they are now (it is a new manœuvre evidently shewing their weakness) abusing and depreciating the gentlemen whom they have before, I confess, admitted to be every way qualified for, and worthy of, a seat at the Board. Know not the Fellows these facts, or do they shut their ears as well as remain apathetic as regards their friends and the honour of the profession?

They cannot now at all events plead ignorance as an excuse, for your Journal is indeed ubiquitous; finding its way not only into the Surgeries and Consulting Rooms of the Fellows and profession generally, but to a corner of the Council Board itself. My earnest wish is that the honest, manly, and straightforward sentiments so universally enforced in your ably written journal, may tend to correct the somewhat extraordinary ideas which the gentlemen of this immaculate body have of what is "honest and manly, and straightforward."

I am, Sir, your obedient servant,
AN ODD "FELLOW."

Monday, July 21, 1845.

(1) Our humble friend merely served up a hash made out of information given by us two or three weeks since.—ED.

THE PULSE IN INFANTS.—The following are the conclusions drawn by M. Valleix from a series of observations made by him on the pulse in infants. 1st. In newly-born infants, the pulse is less frequent than at the age of six months; the mean frequency while sleeping was 87; but sleep itself being a cause of diminished frequency of the pulse, it is necessary to select a somewhat higher figure as that of the normal pulse. Everything warrants the supposition that this varies in frequency from 90 to 100. 2d. Increase of temperature, even when not so considerable as to be sensible to the subject of the observation, causes an appreciable acceleration of the pulse for each degree of temperature. Further observation alone can teach us what is the exact relation between increase of temperature and acceleration of the pulse. 3d. Although the pulse constantly diminished the frequency in proportion as the day advanced, yet it would be premature to conclude that these facts support those which have been published by Dr. Guy. This author indeed states that the pulse progressively diminishes in frequency from morning to evening. Now all Dr. Valleix' observations on children were made in the morning, and as the children were always fed before they commenced, the acceleration of the pulse in the early hours of the day, and its subsequent diminution in frequency must doubtless be in great measure attributed to this cause. 4th. The least movement is sufficient to occasion a considerably increased frequency of the pulse in children, and the same result follows from any emotion or from mere fretfulness. Those authors who have examined the pulse without bearing in mind these circumstances have thus been unavoidably led to erroneous conclusions. 5th. The influence of sex is very considerable even in young children. The pulse of little girls is in a marked degree more frequent than that of little boys. 6th. The frequency of the pulse diminishes sensibly during sleep. 7th. The frequency of the pulse does not undergo any very marked variations from the age of seven to twenty-seven months; its mean being about 126; or, distinguishing the two sexes, 121 in male children, 128 in female. These numbers express the frequency of the pulse under ordinary circumstances; but assuming the children to be in a state of perfect rest, the numbers would then be 119 in males, 124 in females. 8th. Judging from some observations too few in number to be considered decisive, the pulse would appear to continue a little above 100 up to the age of six years. 9th. The average frequency of inspiration in children between seven months and two and a half years old is 30 or 32; and is to the frequency of the osmp as 1·4.

RETENTION OF URINE.—Dr. Moj'sisovics recommends the following plan for the relief of retention of urine. A smooth and large straight catheter, with an eye at the end, is to be introduced down to the stricture, against which it is to be firmly pressed, and the prepuce is to be held by an assistant against the instrument, so as to prevent the entrance of any air; the surgeon then, by means of a large syringe, which can be accurately adapted to the top of the catheter, injects with a moderate degree of force an ounce of oil, which gradually finds its way through the strictured part and into the bladder. As soon as it reaches the bladder a violent effect to expel the urine is made; when the surgeon draws back the piston of the syringe the oil flows back, and is followed by from three to five ounces of urine. This is sufficient to relieve the patient for the time, and the operation may be repeated after the lapse of half an hour. He adds, that after the use of this plan for a few days, the urine begins to flow of itself, rendering the application more seldom necessary. The syringe should be capable of containing six ounces.

GOSSIP.

ROYAL COLLEGE OF SURGEONS.—Gentlemen admitted Members on Friday, July 11, 1845:—R. G. Brown, W. B. Sealy, J. Le Gros, J. Parkin, C. B. Wood, W. D. Emmett, E. Cousins, R. W. Davies, G. Cheesman, B. Hamilton, F. Nicholle, J. Murphy. July 18:—D. Greaven, M. Hinchliffe, M. E. Rogers, J. Marsh, T. Prytherch, E. T. Watkins, W. E. Browne, R. P. Sparrow.

Mr. S. Cooper is the new President of the Council of the College of Surgeons. The Vice-Presidents are Messrs. Lawrence and Travers; but in reference to the former, it is said yet to be a moot point whether, after the betrayal of his authorship of a "Bat-Club" paper against a personal friend, &c., it will be becoming in the Council to place him in the College's foremost Chair. Mr. Lawrence, it is true, made a becomingly abject apology, but apologies are not a public man's qualifications for high official dignity. But this is a matter for the Council themselves. The National Association, we imagine, would rather prefer the appointment of Mr. Lawrence as a *favourable* specimen.

John Welch, a chemist and druggist, of Stourbridge, Worcestershire, has lately been tried for manslaughter under the following circumstances: It appears that two of the children of a labouring man being affected with ringworm, were taken to Mr. Welch to be cured; he prescribed an ointment to be applied to the scalp, and some powders to be taken internally. On the second visit to his shop he stated, "that the disease was killed,—"but that to make sure, he would give some spirits for one dressing." He then gave an application evidently containing corrosive sublimate. In the evening after this lotion was applied the children were sick and complained of pain in the stomach which continued for two days. On the day after the application vesicles appeared all over the scalp. A medical man was then called, who found the patients in a profuse state of salvation, which which continued until their death. The *post-mortem* appearances were—sloughing of the mouth and gums, and inflammation of the stomach and intestines. The prisoner was acquitted.

A letter from Rio Janeiro, of the 24th of March, states that Dr. Lund, the celebrated Danish naturalist and geologist, to whom we are already indebted for many interesting discoveries in Brazil, has found, in the province of Minas Geræs, a quantity of human bones, including some skeletons complete, in the fossil state. There are many skulls; and nearly all have the principal characters of those of the existing indigenous tribes of Brazil, excepting that in many of them the incisive and molar teeth are exactly alike—a circumstance observed in some of the Egyptian mummies. The writer argues, that as hitherto no human bones have been discovered, in the fossil state, in any other portion of the globe, those found in Brazil would seem to indicate that America, or its southern part, had been peopled before any of the other quarters of the world.

No. 306. SUMMARY. Aug. 2.

CLINICAL LECTURES ON MEDICINE.

Delivered at the Meath Hospital.

By Robert J. Graves, M.D., M.R.I.A., &c.

Allow me to refer briefly to the case of Michael Carey, who lies in the chronic ward, and who has within the last week exhibited symptoms of rather a suspicious character. The account which he gives of himself is, that his illness commenced on the 3rd of March, with rigors, thirst, loss of appetite, and prostration of strength. When admitted, on the 7th, he had thirst, fever, and restlessness, with slight cough, unaccompanied by expectoration. He was treated with aperient enemata, effervescing draughts, and the other remedies which we are in the habit of employing where the fever is not violent, and where there is no inflammatory affection of any internal organ to subdue. Under this treatment his fever began to decline in the course of five or six days, and, with the exception of his cough, which had been gradually increasing and was now very troublesome, he seemed to be fast approaching a state of convalescence. On the tenth day his skin was cool, his pulse reduced nearly to the natural standard, and his tongue cleaning; but the cough had increased in severity, and he complained that it kept him awake at night. Hitherto I had looked on it as merely an instance of that bronchial affection which is so frequently combined in this country with fever of a gastric type, and which generally disappears as soon as a favourable change occurs in the febrile symptoms. The persistence of the pulmonary symptoms, however, in spite of ordinary treatment, induced me to think that there might be something more than mere bronchitis; I accordingly proceeded to make an accurate stethoscopic examination. Over the left side of the chest respiration was pure, and the sound on percussion natural. On the right side, immediately below the clavicle, the chest sounded dull on percussion, and, on applying the stethoscope, the respiration was found to be comparatively feeble over this spot, and mixed with crepitus and bronchial râles. Now the question to decide here was, could this be commencing tubercular deposition, or was it mere bronchitis with effusion into a circumscribed portion of the minute bronchial tubes and air vesicles? It is not very easy to decide this question in many cases. The patient was a young man of good constitution, and apparently not of the scrofulous diathesis; but his cough had resisted ordinary treatment, it was growing daily worse, and he had dulness under the right clavicle, with feeble respiration and bronchial râles. Weighing these circumstances carefully, and recollecting that phthisis frequently comes on after fever in a very unexpected manner, and with great rapidity, I determined to choose the safer side, and treat it as if it were a case of commencing tubercular deposition. I immediately ordered leeches to be applied under the clavicle, to be repeated as the exigency of the case might require, and prescribed the hydrocyanic acid in the form recommended by M. Magendie. He recommends a drachm of the cyanuret of potash to be dissolved in an ounce of distilled water. This solution is stated by him to be equal in efficacy, and capable of producing all the advantageous effects of hydrocyanic acid, at the same time that it is less volatile, less liable to undergo change, and can be always prescribed of the same strength. He says that it possesses all the beneficial properties of hydrocyanic acid, in relieving the irritative cough of phthisis, or the excitement which accompanies gastric derangement. Of this solution I ordered the patient to take one drop in half an ounce of water every fourth hour, to be increased in the course of three or four days to double the quantity. On making an examination this morning, I find that his symptoms are improved; there is less dulness on percussion, respiration is clearer, and the crepitus is diminished. On the whole, his condition authorises us to entertain hopes of being able to bring about a cure. If phthisis be curable, or if tubercular deposition admit of being resolved, it is only at the very commencement of the disease, and before that state of constitution is established in which there is a tendency to the formation of tubercular productions. If we happen to be so fortunate as to detect phthisis at this early period, I think that it is possible not only to palliate, but also to remove it. By free and repeated leeching, the use of blisters, a mild diet, and the insertion of one or two setons over the part dull on percussion, you will often be able to remove any threatening symptoms, and perhaps save the patient's life.

The case of Owen Doyle requires a passing observation, not so much with respect to the pathology of the disease, as to some points connected with its treatment. This man is advanced in life, and of a constitution which has been debilitated by constant hard labour, with insufficient food and want of proper clothing. When admitted on the 1st of March, he stated that his illness occurred eight weeks before, and that within the last three weeks his symptoms had been greatly aggravated. His complaint was constant inclination to go to stool, flatulence, griping, and frequent discharges of fluid matter, unmixed (as he states) with blood. Now what is the nature of his complaint?—is it diarrhœa or is it dysentery? Formerly the distinction between these affections was a matter of great moment; at present, the diagnosis is not looked upon as really important, and in a practical point of view seems to possess but little value. The subject for inquiry in bowel complaint is, not whether it is to be called dysentery or diarrhœa, but what is its source and origin; whether it is the result of congestion, or inflammation, or a relaxed condition of the intestinal mucous membrane, or the presence of irritating matter or worms, or any of the numerous causes which give rise to fluxes from the bowels, accompanied by more or less pain and tenesmus.

In the present case we find that the patient was attacked about eight weeks ago with bowel complaint, and had an exacerbation of his symptoms three weeks before admission; that he has been losing flesh and strength, and, though he has no fever, that he does not sleep at night, and has lost all relish for food. On examining him the day after he came in, two circumstances struck me as indicating the existence of subacute inflammation of the digestive tube. He complained of griping long before the passing of an alvine discharge (on this point, however, I do not lay much stress), and had considerable tenderness all over the epigastric and right iliac regions. The fact, then, of griping before the stools, tenderness on pressure, and frequently recurring alvine discharges, always worse at night, showed that his complaint depended on chronic inflammation. Why do I say worse at night? Because almost every disease connected with inflammation—whether it be fever, or syphilis, or rheumatism, or bronchitis, or pneumonia—is always worse at night. Every one is aware of the evening exacerbation in fever—every one knows that a cough is always more troublesome at night, and that the aggravation of rheumatic or arthritic pains commences with the close of day. Hence, from the griping, abdominal tenderness, and nightly exacerbation of the diarrhœa, I concluded that the man's symptoms depended on inflammation, and that this inflammation was seated in the small intestine.

Having settled this point, our next consideration was as to the treatment. The plan we adopted was simple, and though there were some unfavourable circumstances connected with the case, as, for instance, the advanced age and debility of the patient, it has proved eminently successful. He has been now only ten days under treatment, and yet his bowel complaint is nearly gone, his appetite is greatly improved, and he is gaining flesh and strength. The plan we pursued was this: first, we leeched the belly freely, and ordered repeated fomentations, with the view of removing the tenderness, and, having accomplished this, we proceeded to the exhibition of mild purgatives alternately, with opiates and astringents. We gave a draught consisting of a scruple of rhubarb, two drachms of sulphate of magnesia, and an ounce of cinnamon-water. We did not prescribe this with the impression that there was any collection of fecal matter in the small intestine. Fecal matter collects generally in the large, and very seldom in the small intestine; in the former situation it will sometimes give rise to dysenteric symptoms; and here the use of purgatives affords the best and most expeditious mode of cure. But in the present instance we did not give them with this view, or with the view of relieving the griping and tenesmus of the large intestine, by acting on the upper part of the digestive tube, but merely with the intention of changing the action of the mucous membrane. After the operation of the purgative we prescribed chalk mixture, with a small quantity of tincture of kino and laudanum. After having followed up this plan of alternately purging and binding up the bowels for ten days, with great benefit to the patient, we commenced yesterday with the use of sulphate of copper in minute doses. This remedy is extremely useful towards the termination of chronic affections of this description; it acts as a tonic and astringent, strengthens the tone of the intestinal mucous membrane, and tends to prevent the occurrence of a relapse.

COURSE OF LECTURES ON THE THEORY AND PRACTICE OF MEDICINE.

Delivered by C. J. B. WILLIAMS, M.D., F.R.S., Professor of the Practice of Medicine, and of Clinical Medicine, at University College.

Fever, complicated with local affections, is to be treated with reference as well to the type of the fever as to the complication. Complicated fever may be of the inflammatory kind, with hard, full pulse and hot skin, and where there is a local affection combined with it, there can be no doubt about the propriety of blood-letting; but even in such a case, when the fever is of a specific kind, the blood-letting is less easily borne than in simple inflammations, and it is therefore not advisable to carry it far. Local blood-letting is perhaps the chief remedy after one general bleeding. There are very few cases of the typhoid kind that will bear general blood-letting. In the early stage it may be practised, but attention must be paid to the general strength. Even in those complications where low inflammation exists, it is preferable to use general stimulants at the same time. Where inflammatory affections of the brain occur in the course of fever, depletion is better borne than in any other complication. The other measures that may be useful in meningitis, particularly in its early stages, are purgatives and cold to the head, according to the amount of the strength. Every one of these agents is depressing, and must be watched. I have known the ice bladder in many instances produce very alarming depression; under similar circumstances often a pediluvium is useful; and where there is affection of the brain, the application of scalding water to the feet may be used.

We may say much the same with regard to the chest complications. There are a few cases in which blood-letting is borne early; this is to be combined with antimonial treatment, and carried out as fully as the patient will bear it. If the pulse is low, mercurial treatment is a better substitute. In the low congestive form where the lung has not unfrequently become loaded with blood, and there is dyspnœa and dulness on percussion, or dulness on both sides, combined with great weakness of the pulse, it is sometimes useful to abstract a little blood by cupping, but dry cupping is of more service. Rubrifacients, sinapisms, or turpentine fomentations, are sometimes of use in these cases, and they may be combined with wine and stimulants to support the system under the depression caused by drawing blood. Where the powers are sinking, and expectoration appears difficult, there is great danger of chest complication, and carbonate of ammonia should be used, as in other chest diseases. The same thing may be said of adynamic cases combined with flux into the bronchial tubes. With regard to the chest, the patient should change posture from time to time, on account of the hypostatic congestions that are so apt to occur, and which are so mischievous in their results. There is not merely a temporary mischief arising from the temporary oppression to the function, but likewise a tendency to tubercular productions, which occur from time to time.

The abdominal complications may often be moderated and considerably prevented by keeping the secretions of the abdomen free in the early stage, not by drastic or active purgatives, but by using mild and alterative aperients; but in many instances there is such an amount of complication even at first, that it is necessary to treat these complications. In the early stage, there is an undue proportion of heat and tenderness in the abdomen, a peculiar redness of the tongue, and more thirst than in uncomplicated cases. It is often useful in the early stage to apply leeches to the abdomen, followed by fomentations or poultices; they are the means of relieving the abdomen without interfering with the strength. The measures useful in gastro-enteritic inflammations of the slighter kinds are hot water dressings applied over the whole of the abdomen, or flannels wrung out of hot water and covered over with Mackintosh cloth. This constitutes a sort of warm bath. The general treatment is to be mercurial; hydrarg. cum creta in small doses, and calomel and blue pill. If the bowels are not opened without additional assistance, small doses of castor oil answer better than any other aperient; or injections from time to time are useful. When the patient is very low, fomentations, or blisters, or sinapisms, are of considerable service. If there is diarrhœa, it is not to be hastily stopped, unless the patient is exhausted by it. Moderate diarrhœa is a favourable symptom in fever, and appears to be connected with an attempt to get rid of the morbid matter. When the diarrhœa is such as to cause considerable irritation, the bowels are opened three or four times a day, and the quantity is so considerable that faintness ensues, then it should be moderated; and this may be commonly done by the exhibition of hydrarg. cum creta and Dover's powder, and by administering opiates and opiate enemata, with fomentations and sinapisms.

The diarrhœa continues sometimes in the latter stages of the fever, and the evacuations from the intestinal canal are often remarkable; ulcers are formed, and you see traces of them in the evacuations, and the secretions are discoloured. This exists without tenderness of the abdomen, and the indication in these cases is to try to heal the ulcers. We are quite justified in concluding that these ulcerated intestines may be healed. It becomes an indication to promote the cicatrization of these ulcers, to keep the secretions moderate, and allay the irritations arising from the feculent matter by sugar of lead, sulphate of lime, or sulphate of copper, combined with opium. It is necessary here to evacuate the intestines, and the sulphate of potash answers best.

In these cases tonics are borne badly. Quinine, which is a good remedy in some fevers, in these cases is not borne; it causes griping, and so do the mineral acids; but in the diluted form, combined with mucilaginous liquids, they are sometimes borne.

In all cases the occurrence of convulsions is very important, and they require careful management. Relapses are very common, for all the bodily powers are reduced to a very low standard, and are easily upset. The whole system is terribly shattered and weakened by the influence of the cause of the fever, and the stomach is very liable to be disordered by various influences, both external and internal; time is the best restorative, provided all the *hurtful* influences are avoided, and the chief part of the treatment is to avoid them. The patients should avoid too early exertion, or exposure to cold, or excessive heat; the diet should be very carefully regulated, and should return to animal food in the adynamic cases, but not too much at a time, and even for a long time small quantities of the lighter foods are best. The patients have enormous appetites, and it is necessary to guard against a too free use of animal food, for relapses are more frequent from this cause than any other, and the result very often is visceral disorder. It is more necessary to be careful as to the diet, in case of gastric complications. Mental excitement, or mental exertion of any kind, should be avoided for some time, particularly in the cerebral complications. The most effectual of all tonics is quinine, and it is remarkable how, under the influence of this remedy, slight remains of fever and local affections will disappear.

There is another fever of a slighter kind, but really almost a serious disease from its frequency, that is, influenza, or catarrhal fever; or *la grippe*, as it is called by the French. This appears to be essentially a febrile disease, of the same class as the last one I have been describing. It occurs especially as an epidemic, and is remarkable, when it is severe, for its rapid turn to inflammation. In various instances, three-fourths and nine-tenths of a whole population have been affected with this disease; hence, it is important to be acquainted with it, although in many instances it is slight, and the mortality very low, not more than 2 per cent, yet, from the great number affected, it becomes important, and likewise from its ulterior effects; for though the influenza may be severe at the time of the disease, it is not immediately fatal in its consequences; yet it is quite certain that in many instances it does do mischief; it gives the constitution a shock, and frequently sets up affections in particular viscera.

The symptoms that occur are, shivering, pains in the back and limbs, and in the forehead and nose, smarting in the eyes, loss of appetite, furred state of the tongue, disordered bowels, urine scanty and high-coloured, pulse very various, frequently changing very much in the day; in some instances in the severe form, it changes from 140 down to 80 sometimes there is profuse sweating, which is one of the essential characteristic symptoms in the severe form, and extreme prostration and weakness of body and mind, with depression of spirits. The fever lasts from two to six days, and usually terminates by profuse perspiration, and copious deposit in the urine, leaving the patient very much weakened. Still, in a great number of cases, although this happens, and the patient will not take to bed, he still complains loudly of exhaustion and suffering. One of the most characteristic parts of influenza is, that it is usually accompanied by local symptoms which, in many instances, predominate over the febrile affection; in most cases this affection is catarrhal; a sort of bronchitis occurs; coryza afterwards affecting the air tubes. Sometimes the effect is cephalic, with vertigo, headache, delirium, and even coma, with a dilated pupil. Another complication of the local affections is the gastro-hepatic evidenced by vomiting, pain and tenderness in the epigastrium and the right hypochondrium, and occasional jaundice; or sometimes the complication is intestinal, and then there are colicky pains and diarrhœa. Sometimes the external parts are affected, and the lymphatic glands in various parts become swelled. In many instances eruptions appear on the surface, being those of herpes, &c. There is also a rheumatic and neuralgic form. All these different varieties are produced apparently, partly by simultaneously acting causes, as cold, and so forth, and partly by predisposition of the individual. During the prevalence of influenza in different individuals these different forms are presented; but the occurrence of the disease among so many, simultaneously, is enough to prove its tendency.

Of the causes we must obviously refer to epidemic influence as one, but this may prevail in various seasons. The severe influenza of nine or ten years ago began in the winter, and returned again and again in varied forms until the summer. There can be no doubt that it is produced by some morbid influence. It is less fatal than fever, because the period of its duration is shorter, but the complications arising out of it are not free from danger, especially in the pulmonary complication; it lays the foundation of disease by the low congestions and inflammations it produces in the organs, particularly in the lungs. Many cases of pulmonary consumption are referable to an attack of influenza.

The treatment in simple cases is merely slight febrifuge medicine; an emetic and mercurial aperients are followed by immediate relief; they cut short the disease. Antimonial salines will do. They must be followed by tonic remedies. The patient should be confined to the house, at least. The complications may require local antiphlogistic treatment in a moderate degree, varying according to circumstances. Coryza and the humid catarrhal variety may be cured under dry diet. Afterwards the chest affections may be treated with slight doses of tartar emetic, and with squills and acetate of ammonia. Blisters in cases where the expectoration is profuse are useful, and sugar of lead has been found beneficial. In cases of gastro-hepatic complication, mercurial medicines with saline purgatives should be used.

We now come to the exanthematous and eruptive variety of diseases, which are of a very distinct kind, arising chiefly from infection, and essentially febrile in their character, the fever being more of the idiopathic variety than the symptomatic type; more like the continued fever I have been just adverting to than the inflammatory. Still this eruptive fever is something more. There are inflammations almost universally affecting the skin, but most of these eruptive fevers of the skin are accompanied by inflammations of other parts, more particularly of the mucous membranes. From the constancy of the local inflammations and their specific character, we are led to refer them to the operation of specific poisons; and these poisons seem to operate both on the whole system, producing an influence very much like that produced by the cause of continued fever: its reducing effect first and its reaction afterwards; but in addition to this the local inflammations appear to be a direct effect of the poison it excites inflammations in particular parts or organs The skin is usually the seat of this peculiar affection, but other parts are also affected. There is in scar-

latina a throat affection besides that of the skin. There is also a catarrhal affection of the bronchial mucous membrane, and sometimes the air tubes and the intestinal canal are the seat of pustular inflammation. In the case of the plague, the cellular tissue and the glands became the seat of the peculiar inflammation of the poison. This poison is not merely sedative in its action, but it has the properties of a local irritant, and we find the same thing with regard to other palpable poisons: arsenic, corrosive sublimate, mercury, the rattlesnake, and some other animal poisons.

There is something in eruptive fevers that we cannot find any analogy for; after they have occurred once in the body, there is no recurrence of them; they affect the system but once in the life of the individual. This is the common and universal rule. It is quite a mistaken assumption of Liebig and others, that the cause of the disease is a kind of ferment, something that produces decomposition in some matters in the body. This is entirely gratuitous, and before such an opinion is assumed, something substantial must be pointed out as the substance on which this fermentation is produced. There is no evidence whatever that there is such a difference in the composition of the soft parts before and after the eruptive fever. To the rule I have mentioned there are some exceptions; generally speaking the affection occurs only once, but even in all diseases, measles and small-pox, there are instances in which it does occur again, although they are very rare. Erysipelas, instead of protecting the individual from a future attack, seems to predispose to its recurrence. It is doubtful whether the plague may not occur again and again in one individual. Now, assuming the cause of eruptive fever to be a poison, like all the continued fevers, it is obviously of a very different strength in different cases. The eruptive fevers vary from other fevers in their different ratio of mortality, showing a difference in their violence. The eruptive fevers exhibit remarkable changes of type and complications, and in many instances these types and complications may be traced to the same causes as in continued fever. In all these cases the eruptive fever is distinct; there are symptoms of fever before the eruption occurs, and therefore it is obvious that the disorder does not depend on the inflammation. The peculiar character of the eruption also shows the irritant nature of the poison. The inflammations in the skin are not common inflammations; they exhibit peculiar characteristics. Eruptive fevers differ from common fevers in their tendency to run a more distinct and definite course than continued fever, and this varies very much, sometimes being prolonged very considerably, and sometimes being of much shorter duration. The dangers accompanying these eruptive fevers do not arise from the cutaneous inflammations, but chiefly from the depressing influence of the poison, or from the local inflammations. The eruptive fevers are often the cause of much mortality, and from their affecting almost all individuals once in their life, they become universal diseases, and demand great attention both in regard to their diagnosis and their treatment.

First, I must advert to scarlatina, or scarlet fever. This disease is obviously of a dangerous kind, but many persons entirely escape it. That contagion is the cause of it is generally admitted; now, the contagion has been known to be carried in the clothes of a third person. The infection is apt to adhere to the clothes, and to rooms and apartments, where fever patients have remained long. There are three varieties generally distinguished: first, the *simplex*, where the disease is mild; secondly, the *scarlatina anginosa*, the disease being inflammatory, and chiefly combining throughout with other complications; and thirdly, the *scarlatina maligna*, or the typhoid form of scarlatina, in which the eruption is more evident, and there is the greatest amount of disease, commonly of the congestive kind, and often complicated. *Scarlatina simplex* is a slight disease; three or four days after exposure to the infection, febrile symptoms occur for a day or two—not a long period—with shivering, heat, and so forth; slight swelling or redness, slight red spots occurring first of all on the face, neck, or front part of the chest; on the third day they spread to the whole surface, and affect the trunk and the extremities. The colour of the eruption is a bright crimson—scarle is not a proper term for it. It is more scarlet a great deal than many eruptions, but scarlet does not distinctly convey to the mind the right colour; it is a bright, florid, red colour, more of the character of arterial blood. It reaches to its greatest redness at the bends of the joints, the chest, the pit of the stomach. Some parts of the skin are more affected than others. There are interstices left between the patches of redness, and these are often very irregular in their shape. In this respect there is a difference between it and roseola and rubeola. The redness is most apparent in the evening, about the evening of the third or fourth day; on the fifth it declines and becomes less, and the interstices increase. The eyelids and the nostrils, but rarely the mouth and fauces, exhibit redness; the tongue is white, with enlarged crimson papillæ peeling off it, and it often becomes denuded. Sore throat is usually present to a slight degree, but it is not much complained of. All these symptoms disappear about the sixth or seventh day, and exfoliation of the cuticle takes place in a very remarkable manner.

REPORTS ON DISEASES OF FEMALES.
By EDWARD RIGBY, M.D.

Fellow of the Royal College of Physicians, Senior Physician to the General Lying-in Hospital, Lecturer on Midwifery at St. Bartholomew's Hospital, Examiner on Midwifery to the University of London, &c.

(Continued from page 312.)

S. B., ætat. 41, mother of four children.

June 21, 1836.—Complains of much bearing down, with frequent lancinating pains; has had a leucorrhœal discharge for many years of variable character, being sometimes albuminous, at others creamy or purulent.

Examinatio per vaginam.—Os and cervix uteri in the natural position, but hot and painful on pressure; os uteri nearly closed; the catamenia are present, which relieve her considerably, but previous to their appearance she does not feel so well.

℞. Extr. gentianæ, Extr. hyosc. āā gr. v. o. n.

℞. Magnes. sulph. ℥ ss, Magnes. carb. gr. xv, Aq. menth. pip. ℥ iss, o. m.

℞. Lotio plumbi.

28.—Has had lancinating pains for the last two or three days; the discharge is less in quantity, but creamy; the bowels have not been properly relieved for the last two or three days; complains much of pain in the back.

℞. Pulv. jalapæ co. omni alterno mane. Rep. alia.

July 8.—No lancinating pains since last report; all her other symptoms have improved; the discharge is more like simple leucorrhœa. Pergat.

15.—No lancinating pain; complains of much dull and occasional throbbing of the right groin, which is not painful on pressure; bowels are open, and she feels generally better. Pergat. Hirud. x. inguini dextro.

Aug. 5.—Has gone a week without medicine, and is not so well; the discharge is white and increased in quantity; has had no lancinating pains; the leeches relieved the pain of right groin only for a day or two. Pergat.

Sept. 2.—Has absented herself since last report; lancinating pains have returned, with white creamy discharge; has pain on sitting down suddenly on a hard seat, and during the passage of costive evacuation; in other respects the health is pretty good. Pergat.

9.—Lancinating pain has only been felt once; the discharge is thinner, and she feels better. Omitt. pil. et lotio.

℞. Pil. ferri. co. gr. x. o. n.

℞. Ferri. sulph. ℈iv, Aquæ distillatæ ℥viij, solve. ft. lotio.

16.—No lancinating pain at all; the discharge is less; it is thin and white, like simple leucorrhœa; general health better.

Oct. 7.—Much better in every respect Pergat.

14.—The same.

The case, at its commencement, was evidently one of inflammation of the os and cervix uteri, and which, having been allowed to run on, had gradually assumed the chronic form, becoming every now and then more active, as seen by the occasional increase of darting pains, and return of the discharge to its former white creamy appearance.

The symptoms of inflammation of the os and cervix became very distinct (Sept. 2) after her ceasing to attend for some time, and it is interesting to observe, as her symptoms improved, how the discharge began to assume more and more the character of simple leucorrhœa.

Mild saline laxatives and Goulard lotion are generally the best in such cases, and it was not until some time afterwards that I ventured to use any decided form of tonic, or any other topical application.

In cases of local congestion without much general functional derangement, preparations of iron seem preferable to most other tonics; by giving strength to the system they appear to give tone to the vessels, and to equalise the circulation. Feeling assured that all inflammatory action about the os and cervix uteri was removed, and that if any congestion remained it was of passive character, I used the lotion of sulphate of iron with a similar object, and evidently with good effect.

Although the above case affords an example of but one of the very numerous sources from which chronic leucorrhœa may have its origin, I do not propose to make this a subject of special consideration. To illustrate the numerous varieties of chronic leucorrhœa with cases, as if it were a specific and primary disease, and not the result of other affections, would be obviously unpractical and also needless, as its characters will frequently come under observation, whilst treating of those diseases, among the symptoms and effects of which it hold a prominent position.

Where chronic leucorrhœa has a purulent or muco-purulent appearance, it is generally the result of local irritation, as from a slight degree of prolapsus uteri, to which I have already alluded; from retroversion, or, more properly speaking, retroflection, of the unimpregnated uterus; from the presence of polypus; from ovarian disorder or disease; from irritation in the rectum, as from scybala, hæmorrhoidal congestion, stricture, or other disease of that bowel; or from disorder or disease of the bladder, urethra, or kidneys. A similar muco-purulent form of chronic leucorrhœa is seen after the acute species, whether in consequence of an attack of gonorrhœa or acute vaginal catarrh. I have already stated that it may result from that rheumatic gouty condition of the uterine system, connected with mal-assimilation, which I have alluded to when speaking of dysmenorrhœa.

Where it has a watery character, more or less mixed with mucous and purulent matter, where it is of a dirty brown, yellow, or greenish colour, and above all, fetid and very profuse, coming in gushes with every movement, from its rapid accumulation in the vagina, and evidently attended with considerable failing of the health and strength, there will be great reason to fear organic disease of the uterus.

There are, it is true, exceptions to this rule; thus we occasionally meet with chronic leucorrhœa of some standing, where the discharge has become excessively offensive, where there is no reason to suspect organic disease, and where by treatment it has entirely disappeared. The discharge also will be subject to constant varieties, even in the same individual, being either more watery, slimy, purulent, &c., according to the degree of congestion or vascular excitement which may happen to be present; thus in every form of chronic leucorrhœa, whether or not the result of organic disease, we find that whenever inflammatory action shows itself, the discharge becomes more or less watery. This is also seen at the commencement of acute vaginal inflammation; the discharge is at first serous or aqueous; it gradually assumes more and more a purulent form as the disease advances, becoming muco-purulent, and ultimately mucous, as the inflamed lining membrane of the vagina gradually returns to a healthy state. In no case are these transitions in the secretions of an inflamed mucous membrane better or more familiarly seen than in a common severe cold.

There are two other conditions in which aqueous discharge may take place, the one depending on the presence of an hydatid mole, and produced by the occasional rupture of a cyst; the other in connection with the vascular tumour which has been called by Sir C. M. Clarke the cauliflower excrescence of the os uteri. Neither of these discharges can be con-

sidered as having any connection with leucorrhœa. Another species of aqueous discharge must also be mentioned, which appears to be a secretion from the lining membrane of the uterus, and is, as far as I know, unconnected with inflammatory action or organic disease. Of this affection I will give an instance, not that it belongs to the subject of leucorrhœa, but simply because I have alluded to it, and have no other head under which I can conveniently bring it.

E. G., ætat. 37; rather stout; twice married; no children; two miscarriages.

Feb. 23, 1836.—Much gastric derangement; the abdomen is considerably swolled, and she has passed several catamenial periods without any discharge. The abdomen is doughy to the feel, except in the umbilical region and right hypochondrium, where it is hard.

Was seized with mental derangement nine months ago, which lasted for four months, at the beginning of which time she believed herself pregnant. Has been tolerably well in health until the last three weeks, when, after some pains in the back and loins, a large quantity of watery fluid (she says nearly half a pailful) suddenly gushed from the vagina, and the abdomen immediately diminished considerably in size.

Examinatio per vaginam.—Os uteri low down in the pelvis, nearly closed, not round; cervix uteri long, hard, and slightly painful; vagina relaxed.

R. Acidi nitrici dil. m. xv, ex infus. gentianæ co ter. die.

R. Mist. potassæ citratis effervescens o. m.

March 1.—Feels much better in health; has some difficulty in passing water, which she does not do more than twice a-day. Abdomen and head is large, but there is nothing defined; has not had much watery discharge since last report, although it still comes in splashes. Pergat.

8.—Complains of much pain in the back; has had two or three discharges of water during the last week.

Examinatio per vaginam.—Cervix uteri thick, less tender; os uteri forms a transverse fissure, and is nearly closed. I passed a catheter through it without much difficulty, but no fluid came away

R. Pil. hydrarg., Extr. coloc. co., āā gr. v, o. n. Rep. alia.

15.—Has had eight or nine discharges of watery fluid since last report; the abdomen is smaller and softer; feels well in health. Pergat.

22.—Has had several discharges of the same fluid, but less in quantity.

Omitt. mist. potassæ citratis. Rep. alia.

R. Quinæ disulph. gr. ij, o. m.

29.—Better in health; very little water has come away; feels much easier when the bowels are briskly moved.

Omitt. quinæ disulph. et pilulæ. Rep. alia.

R. Pil. ol. crotonis, j, o. m.

April 19.—Little or no watery discharge since last report; complains that she cannot hold her water long. Omitt. haust. gentianæ.

R. Sp. ætheris nitr. ʒiss, Sp. ammon. arom., Tinct. hyosc. āā m. xv, Aquæ menthæ pip. ℥iss—M. ft. haust. bis die sumend.

Rep. mist. potassæ citratis o. m.

28.—Much the same; complains that the mixture does not agree with her. Pergat.

May 3.—Has had a slight return of the catamenia; much fulness of head, and mental excitement. Pergat.

10.—Not so well; much pain of abdomen, and general dyspepsia.

Omitt. pil. ol. crotonis. Rep. alia.

R. Pil. hydrarg., Extr. coloc. co. āā gr. v, o. n.

17.—Complains of much pain in the back, with bearing down; has had a slight discharge of clear water; rest much disturbed.

R. Confect. sennæ, om mane.

R. Pil. Saponis c. opio, Extr. gentianæ, āā gr. v, o. n.

Rep. mist. potassæ citratis.

31.—Has been unwell twice in the month (on the 2d and 22d); during the latter of these periods she discharged upwards of a pint of water from the uterus; the catamenial discharge came also in the same gushing manner. General health not so good.

R. Pil. cambogiæ co., Extr. hyosc. āā gr. v, o. n.

Rep. haust. gentianæ c. acido nitrico.

June 7.—Has had frequent vomiting since last report, which she attributes to the pills.

Rep. haust. gentianæ et mist. potassæ citratis, Omitt. pil.

R. Pulv. jalapæ co. ℈j, p. r. n.

14.—Much better; bowels well opened; appetite good; no sickness; sleeps well. Pergat.

The source of this watery discharge can only be referred to the uterus. The gradual enlargement of the abdomen, the pain in the back and loins, like labour pains, followed by a sudden profuse discharge of watery fluid from the vagina, and consequent diminution of size, the absence of abdominal fluctuation, and the catamenia coming in the same gushing manner as the discharge had done, are the symptoms which favour this view of the case. On the other hand it may be stated that the enlarged uterus was not distinctly felt through the abdominal parietes, and that no peculiar enlargement of the inferior segment of the uterus had been detected on vaginal examination beyond what might be attributed to the presence of slight prolapsus.

From the irregular manner in which the catamenia appeared, and the circumstance of a considerable quantity of watery fluid being discharged during one of these periods, I am inclined to the opinion that the discharge was furnished by the vessels of the membrane which lines the cavity of the uterus. I suspect that it is much of the same nature with the watery discharge which has been sometimes observed during pregnancy, and which has been termed "*hydrorrhœa uteri gravidarum.*" In the cases of this affection which have been recorded, the patients have mostly suffered from vomiting during the first months of pregnancy to a greater extent than ordinary, and from severe rheumatic pains in different parts of the body, which they attributed to having caught cold. The abdomen has been observed to swell rapidly at about the fourth month; in other cases, the size of the patient has not excited attention. The discharge has commenced without any assignable exciting cause, and has continued at intervals to a very considerable extent. Thus, in one case, the entire quantity was estimated at upwards of 60 pints. The discharge has also been attended with uterine pain. In spite of all these apparently unfavourable circumstances, the pregnancy has generally gone on to the full term, and a living child has been born. In almost every instance where the membranes have been carefully examined, the chorion and amnion have been found closely adherent to each other over their whole extent, and in many cases the cord has been of unusual thickness, and distended with a gelatinous fluid.

Antiphlogistic and tonic treatment have both proved successful, according to the nature of the individual case; but in either, when complicated with rheumatic symptoms, the use of Dover's powder has been attended with much advantage.

The pale cachectic appearance of the patient whose case I have just recorded, although by no means emaciated, induced me to give tonics, and to regulate the bowels with laxative medicines. The relief which these latter afforded when sufficiently active, and her own testimony as to feeling better when smartly purged, encouraged me to give more powerful aperients, and with good effect. I cannot say that the diuretic appeared to give any relief at all.

PATHOLOGY OF EXPECTORATION.

By S. Wright, M.D., Edin., F.S.A.

Physician to the Birmingham General Dispensary, formerly Senior President of the Royal Medical and Royal Physical Societies of Edinburgh, &c. &c.

Pathology.—The secretion of pus by a mucous membrane is usually connected with a state of irritation or inflammation, which is very self-evident and demonstrable. Whilst, however, this perverted secretion may be consequent upon the severest forms of irritant or inflammatory action, it may also be dependent upon a similar action of so feeble intensity as to be neither recognisable in its progress nor at its termination. Pus will sometimes be discharged profusely by the bronchial membrane, without the patient complaining of the least pain or uneasiness,[1] and the instances are numerous enough of purulent expectoration up to the period of death, and yet no morbid appearances in the bronchi or lungs being detectable. But it is not to be inferred that there is *no* lesion, because our senses do not enable us to discover any; there is probably never an altered function without more or less change of structure—evident or inappreciable. Still it is a curious fact in pathology that whilst an action, most laboured and energetic, and inevitably leading to structural alteration, will give rise to the formation of pus, this secretion will also be the issue of an action which in no particular, except that of produce, can be shown to be abnormal. Whenever pus is secreted by a mucous membrane, in large or small quantity, it is always an indication of deranged function, which has its origin either in local nervous excitement, or in undue vascular action.

Though the *post mortem* appearances after purulent expectoration are often not appreciably morbid, yet are they more frequently very characteristic and definite. The lining membrane of the trachea and bronchi is sometimes found thickened and indurated, at other times tumid, semi-transparent, and œdematous; again, it will exhibit patches of vascularity, of every degree of intensity and extent, or marks of ulceration as variable in severity as in size. In other cases the mischief is found extending to the lungs, which may be œdematous, congested, hepatised, or infiltrated with pus.[2] In others, again, we have tuberculisation of all grades, from the primitive miliary deposit to softening and the formation of cavities. When these are lined by a substantial membrane, it is the latter chiefly which furnishes the pus of expectoration; but when the parietes of vomicæ consist of unprotected pulmonary tissue, the purulent sputum is mainly secreted by the bronchial membrane.

Treatment.—Of course remedial treatment can be only prescribed with any fair chance of success when the air-tubes and lungs are free from structural injury. Under opposite circumstances our services can at best be only palliative. The general remedies which I have found most effective are tonics. I prefer the lighter preparations of iron, as the muriate and potassio-tartrate; quinine often does good, especially in mixture, acidulated with sulphuric acid. In the chronic affections of old people, copaiba is sometimes of the greatest benefit. The inhalation of watery vapour, or of iodine, or chlorine, is an excellent auxiliary. I have seen cases cored by these means alone. Counter-irritation is generally useful. When the weather is favourable for exercise in the open air, it should never be neglected.

Tuberculous Sputum.—By this term is to be understood the expectoration of tubercular substance, either alone or accompanied by other matters. The tubercle coughed up is always in a crude (matured) or softened state. Cabanis, in his Treatise on Catarrhal Affections, speaks of having observed in the sputa small concretions, sometimes globular, sometimes angular, and transparent as crystal. These would seem to have been miliary tubercles. I have never seen them expectorated myself, detached from the pulmonary tissue, nor have I ever heard or read of a case sufficiently authenticated. Portions of lung that have been detached by the inroad of cavities have been expectorated, and found to contain in their substance tubercular deposit, both miliary

[1] Dr. Stern had a patient who "expectorated near two ounces of pus at a time," yet without suffering any ultimate injury.—(Medical Advice to the Consumptive and Asthmatic, 1768, p. 289.) Recovery from purulent expectoration was familiar enough to the older authors, who thought that the spitting of pus always indicated "ulcers of the lungs." Hence their frequent allusion to these morbid states.

[2] A remarkable instance is mentioned by Van Swieten, occurring in a subject who was asphyxiated after having expectorated an enormous quantity of pus. "Mirabatur utique pus exire, dum cultello secaretur pulmonis substantia: non autem exibat pus magna copia simul, sed gutta una vel altera tantum, ex dissectis nempe asperæ arteriæ propaginibus."—Comment. in Boerh. Aph., tom. iv. p. 60.

and matured; but miliary tubercles are never expectorated alone.

Appearance and Qualities.—The nature and properties of crude and softened tubercle we have already described, and have given ample tests for the recognition of these substances. Now tuberculous sputum, in its simplest and purest form, is merely crude or softened tubercle, without the admixture of any extraneous matter. In the *crude* form, it, of course, looks yellow and cheesy, and crumbles more or less readily under the fingers. It is rarely complained of as tasting or smelling disagreeably—often it is utterly inodorous and insipid, but sometimes the reverse happens. It is discharged (usually with severe coughing) in masses varying from the size of a pin's head to that of a horse bean or a common nut. *Softened* tubercle, at the time of its discharge, looks like cheese or curd, irregularly broken up, with a little thin mucus or serum. Sometimes the particles are granular and of uniform dimensions, but more frequently large and small fragments are found intermixed. This sputum is generally either acid or alkaline; chiefly the latter, owing to the presence of ammonia or its hydrosulphuret. Its taste is usually disagreeable, and its odour offensive.[3] These, of course, vary with the length of time the matter has been detained, and the amount of decomposition it may have undergone.

More commonly, however, tubercular matter is expectorated along with different fluid substances, such as mucus, pus, serum, and blood.[4] According as these are coloured, or dense, or diluted, will the appearance of the mass vary. This sputum, indeed, is so diversified, owing to these accidental circumstances, that it is unnecessary to bestow upon it any further description.

In testing this sputum, it is advisable to separate the tubercular-looking particles and examine them singly: afterwards, the fluid matter may be diluted with two or three times its volume of distilled water, passed through a coarse filter, and tested for albumen. I have before observed that the amount of albumen in sputum is a measure of inflammatory action, either general or local, in the respiratory organs. The softening of tubercles always produces more or less irritation and inflammation in the contiguous pulmonary tissue: this action is often not detected until it has assumed a serious, and even a fatal character; but in milder cases, when its progress is less rapidly destructive, it does not fail to hasten the fate of its victim. For this reason it is desirable to examine the sputa of consumptive patients from time to time, that any increase or variation of morbid function may be met by corresponding treatment.[5]

Pathognomonic Relations.—Tuberculous sputum is always connected with a scrofulous diathesis, and generally, but not invariably, with a tuberculous degenerescence, more or less extensive, of the lungs. In a great majority of cases the expectoration of this sputum is an indication of the softening and breaking up of tuberculous deposits in the lungs, and the consequent formation of cavities. After the complete formation of a cavity or cavities, the discharge of tubercle by cough is as likely as not to cease, unless the disintegration of fresh masses give rise to fresh occasions of expectoration. Though, as a rule, this sputum is an evidence that tubercles have softened or are softening in the lungs, and is therefore, in some sort, a measure of the local mischief in progress, yet it sometimes happens that there is no such relation of circumstances.[6] I am at this time attending a patient who frequently expectorates crude tubercle, and yet I am satisfied that the tubercular deposit, which is sufficiently manifest at the apex of each lung, has not yet passed into the matured state. The symptoms and signs, both general and local, are exclusively those which indicate the presence of miliary tubercles. The patient is an athletic man, with some stamina to aid him, and he has so much improved under local counter-irritation with iodine, and the use of tonics and iodine internally, that I am not without hope the disease may be either completely suspended for a time, or at least that its fatal progress may be very materially retarded. Several cases of this kind I have met with in the course of my practice, and I have generally found that when tuberculous matter is expectorated without the previous condition of the lungs altering, or the matter deposited in them softening, the patient's condition either improves for a time, or the ravages of his malady are for a while, or for ever, arrested. Two years ago I attended a man in the first stage of consumption; the progress of tubercular deposition was carefully but easily traced in the left lung from time to time, until the entire of its summit became loaded with tubercle; for a while the mischief appeared to be stationary, and then the patient, with an aggravation of cough, began to expectorate tubercular matter. But with all this, there was no evidence whatever that the deposit in his left lung was changed—certainly it had in no degree softened. For months he coughed up at intervals matured tubercle, and slightly improved both in strength and weight. He at length began to suffer from scrofulous degenerescence of a remote organ, of which he died. On examination, the right lung was found healthy and entire throughout; the summit of the left lung was a mass of miliary tubercles, but not one was found in a state of cheesiness or softening, nor was there a cavity, or a trace of one, throughout the organ. In another case, after an extensive deposition of tubercular matter in the summit of the left lung, the patient began to expectorate pus and crude tubercle, yet without any alteration in the state of his lung; the expectoration continued for three months, the patient rather improving during that time. He was then sent into the south of Devon, where he sojourned for half a year, and came home entirely free from cough and spitting, but with the summit of his lung just in the state it was previously. He has thus continued during the last two years, and I think is likely to continue for many years to come, if he persist in a careful management of himself. But though to all external appearance and purpose he may be said to be in good health, his life is precarious enough. The tubercles that are now quiescent, and may possibly long remain so, are yet liable at any moment to be roused to their further action (maturation) by any disordered or excessive function in the contiguous pulmonary tissue. Directly that these tubercles have matured, of course they lose the low vitality they had, are no longer influenced by the vitality of the parts they touch, and left to the exclusive play of chemical affinities, they render the patient's life not worth a week's purchase. In a third example, after the commencement of a not extensive tubercular deposit at the apex of each lung, the patient became attacked with diarrhœa, and with a copious occasional discharge of mucus and crude tubercle *per anum*. It was a complete diversion from the lungs, for the cough and expectoration, that had previously been somewhat troublesome, entirely ceased, and never returned again. The diarrhœa lasted for upwards of two months, and then slowly subsided, leaving the patient stationary. Twelve months afterwards he had not altered.

Cases like these, with which I have no doubt every man's practice is more or less familiar, give us at least some hope and encouragement in treating the commencement of that formidable disease—consumption. They tell us that our patient is not necessarily to be sacrificed so long as the tubercles remain in their primitive state, and urge us to the application of such remedies as may locally divert the morbid action, and contribute to the general health and strength of our charge. The indications of tubercles passing to their matured stage will be given, as far as they are known, under the next head.

Not only may tuberculous matter be expectorated when only primitive or miliary tubercles exist in the lungs, but also when the lungs are utterly free from tubercular deposition. I once examined the lungs of a female, who, during the latter years of her life, frequently expectorated both tubercle and pus, and though no evidence of pulmonary disease was furnished by the stethoscope, yet the case was declared to be consumption. *There was neither a tubercle nor a cavity to be met with in the lungs.* Other like cases have been recorded. In instances of this kind, it is plainly evident that the tubercular matter has been discharged by the lining membrane of the trachea, or bronchi, or both. The formation of this matter has been commenced, as is perhaps generally the case, in the blood, and instead of the aggregated granules being deposited in some tissue therein, as in a nidus, to develop themselves into a miliary tubercle, which, sooner or later, by its own inherent action, aided by external circumstances, may pass on to an imperfect further development (crudity)—all these changes occur in the blood-vessels, and the matter so formed, like pus similarly originated, finds an exit by the most convenient outlet—and none is so convenient as the mucous membrane of the bronchi or bowels. The formation of tubercular matter is always referrible to a constitutional peculiarity, the great representative of which is the blood. In this fluid is commenced the formation and function of particles that are hereafter, in their aggregate, to represent healthy or diseased structure. Tubercle is one of these things. Primitively there is the merest shade of difference between an incipient tubercle and the radicle of a normal cell—but there *is* a difference, and it increases with the development of each, until the one becomes matured into healthy tissue, and the other degenerates into a mass of rottenness. When this matter, instead of being commenced and completed in the blood, and discharged therefrom as any other foreign or offensive matter usually is, is scattered or infiltrated through the tissue of an organ essential to life, its subsequent decomposition and discharge necessarily involve the fate of such organ, and hence, for the most part, the reason of the deadliness of consumption. The matter of tubercle, on the other hand, may be generated in the blood with the same impunity as pus, nay, with more, provided that always a ready escape can be found for it. I am satisfied that the instances of tubercular formation in the system, that is, in the blood, and its escape by one outlet or another, are far more numerous than people generally suppose. The obvious good effects of continued mild action upon the bowels, in cases of incipient phthisis, may be owing not so much to counter action, as to the diversion of a morbific matter which otherwise might find its way into the lungs.

OBSERVATIONS ON THE EFFECTS OF HUMIDITY IN TUBERCULAR CONSUMPTION.

By E. B. SHERIFFS, F.R.C.S.E., Professor of Anatomy, King's College, Aberdeen.

The idea that a moist atmosphere is injurious to consumptive invalids is very generally entertained by physicians, and universally so by the public. The consequence is, that those who possess the means, remove to the driest districts of Great Britain, or repair to some sunny, arid clime, as soon as afflicted by this malady. So anxious have some professional gentlemen been to discover a climate the most free from humidity, that they have collected with the greatest care and accuracy the quantity of rain that falls in various counties and

[3] Baglivi gives the following as certain signs of a vomica in the lungs:—"Si quis tussiendo, alba quædam veluti granula excreverit, et granula illa compressa digitis, summopere fœtcant, vomicam pectoris latentem certo denunciant." This definition, as we shall shortly see, is not absolutely correct.

[4] It may also be accompanied by shreds of membrane, portions of blood-vessels, and even detachments of lung.

[5] It has been said that a plant allied to the *penicillum glaucum*, was found by Dr. Bennett in the sputa of a phthisical patient, and Dr. John Hastings affirms that this vegetable invariably accompanies the expectoration of softened tubercle. (See Transactions of Provincial Medical and Surgical Association, vol. xii. p. 109.) I am not able myself to confirm the above statement, but, should it prove to be true, it will certainly furnish us with a very desirable means of recognising tubercle.

[6] It was a notion of the older authors that the expectoration of tubercle always indicated the existence of a vomica in the lung. "Si quis tussiendo, alba quædam veluti granula excreverit, et granula illa compressa digitis, summopere fœteant, vomicam pectoris latentem certo denunciant, præsertim si alia quaque aderint signa, hi rupta vomica utplurimum de repente moriuntur."—Baglivi.

districts, during the year, and from their hygrometrical observations have no doubt furnished us with much valuable information.

My opinion is that there never was a more erroneous nor more injurious idea entertained, than that humidity is injurious to consumptive invalids. I am fully convinced that a moist or damp atmosphere tends very materially to the relief of the phthisical, and that the disease is comparatively rare under such circumstances. I have not come to this conclusion from mere theory or supposition, but from repeated observations made in localities differing the most widely. For instance, on the west coast of Scotland and the adjacent islands, an immense quantity of rain falls throughout the whole year, and the atmosphere is at all times highly charged with aqueous vapour. But among the inhabitants consumption is a disease comparatively little known. Again, in many of the driest counties and districts in England, where the inhabitants would possess the advantage resulting from humidity, we find phthisis very prevalent.

I am much pleased to find similar opinions entertained by a few medical gentlemen, whose talents and experience merit consideration. And as the subject is one involving very materially the interests of the public health, it may be excusable to illustrate it at greater length, particularly as an opinion directly contrary to that offered is so universally entertained. My object is only to elicit truth. I have no favourite whim to indulge and gratify, but feeling as I have ever done the sad results that may follow false views of disease, I am anxious to promulgate that which is likely to serve the interests of humanity.

Dr. Harrison, in "An Address delivered to the Medical Society of Horncastle, on the Endemic Causes of Disease," has offered some valuable remarks on the subject here treated of. He says, "I had not resided long in this division of Lincolnshire, before I was strongly impressed with an idea that the inhabitants upon the wolds were a great deal exposed to idiopathic consumptions, and peculiarly liable to calculous complaints. In the division of Holland, and the extensive marshes of our county, these disorders are probably less known than in most other situations in England. Multiplied experience and numerous inquiries have tended to confirm these opinions."[1] Again, he observes, "The situation of this town has afforded me numerous opportunities to investigate more particularly pulmonary complaints, and I can truly assert that *they are much less frequent in the fens and marshes than in the upper parts of my circuit.* The difference with respect to idiopathic consumption is very great indeed. In some parts where I practise, it is a very common complaint, and in others it is scarcely known to the faculty. Pulmonary consumptions are certainly to be met with every where; but when I have been consulted upon such cases in our marshes or the division of Holland, I could either trace them to other situations, to neglected cold, or some irregularity in the suffering person."

Mr. Weekes, of Hurstpierpoint, in Sussex, has asserted, that in his neighbourhood consumption became more frequent as draining was extended. So long back as the year 1779, the learned Dr. Wells[2] found out that consumptive patients in Flanders removed to the marshy parts of the country for relief, a circumstance that attracted his attention and elicited much valuable information from this gifted physician.

Dr. Speer, of Dublin, has remarked that, "how far humidity, accompanied with severe cold or heat, contributes to the production of disease or health, is as yet a point not clearly settled; the latter would with us seem rather to be the case. Dr. Rutty thought our moist seasons the healthiest, at least much freer from epidemics, and his various observations go decidedly to confirm this opinion; this has also been the opinion of other observers since his time, who think that, unless with great variations of temperature, severe cold, and easterly winds, our humid seasons are in general our healthiest. A single proof of this seems to have been furnished in the year 1816, which was remarkably healthy and remarkably wet. Dr. Franklin, and Dr. Percival, of Manchester, conceived that moist seasons are healthier than dry ones, *cæteris paribus*—Sir John Pringle seems to have been of a similar opinion. It is only, therefore, in its combination with extremes and varieties of temperature, &c., that we can consider humidity in its promotion of disease, and even here we know not how far to go."[3]

It is evident from the statement of Dr. Speer that so far from humidity tending to induce consumption, it is favourable to health—a circumstance which, in my opinion, does not admit of doubt.

Mr. Thackrah, in a most interesting work, gives a mass of information on the effects of humidity. He observes, that "whether we examine the agency of moisture on men in the open air, or those under cover, we find it much less than common opinion would expect. In this country almost all our maladies are ascribed to the agency of wet, or to 'taking cold.' Medical men adopt this notion. It is consequently heard in their expressions; it constantly appears in their writings. The people, of course, have gradually adopted the medical doctrine, and carry it even further than its founders. 'A reference, however," continues he, "to the history of cases attributed to wet and cold, and an examination of the reasoning of the patients, are enough to expose the insufficiency of the evidence and the incorrectness of the inference."[4]

Some years ago I entertained myself by perusing Madden's Travels, and find among my notes an extract bearing on the present subject. In vol. i. p. 221, commences the following passage:—"Indeed Alexandria at all times is excessively damp; the atmosphere is saturated with a saline vapour, which condenses on the walls and furniture of the houses, in small crystals of nitre, muriate of soda, and muriate of ammonia; the soil is everwhere coated with the saline particles, and although it is quite impossible to keep any articles made of iron free from rust, yet the constant breathing of this saline atmosphere does not appear to be prejudicial to health. *Diseases of the lungs are unknown. I have not seen one case of pulmonary consumption among the Arabs.*"[5]

I think, on the whole, that the evidence I have selected in support of my opinion, which has no claim to originality, and is therefore the more likely to be correct, is very conclusive. But still, before leaving the subject, I must refer to the observations of Dr. Lombard, of Geneva, "On the Influence of Professions on Pulmonary Consumption." The following tables, extracted from his paper now referred to, tend still further to confirm the opinion I have ventured to express.

They show, from among a number of deaths that took place among trades surrounded with watery emanations, the relative proportion that was the result of pulmonary consumption.

Occupation.	Total No. of Deaths.	Deaths from Consumption
Weavers	41	2
Dyers	25	0
Tanners	43	4
Watermen	46	3
Bleachers	11	1
Bleaching-women	39	1
Washerwomen	21	1
	226	12

From this it appears that pulmonary consumption is a very rare complaint among those exposed to watery vapour. Let us contrast with these the relative proportion of consumptive deaths among persons whose employment requires them to inhale a dry air. The following table will give us this opportunity, as it shows the total number of deaths occurring among persons surrounded with a dry atmosphere, and the number from among the whole that were the result of phthisis.

Occupation.	Total No. of Deaths.	Deaths from Consumption
Tool-makers	22	6
Enamellers	75	13
File-smiths	37	4
Founders (54)	47	0
Blacksmiths	63	8
	244	31

Dr. Lombard observes that "the result of this table is, that workmen surrounded by a hot dry atmosphere yield more readily than other workmen in the proportion of 127 to 114, from which it may be inferred that if a moist atmosphere is a preservative against consumption, so hot, dry air may be considered as a cause of the disease;" and he afterwards remarks that "it is probable that the frequency of consumption among certain workmen, as clockmakers, jewellers, watch-case mounters, goldsmiths, &c., depends partly on the high temperature of their chafing-dishes, which dries and rarefies the air of their workshops."

I might extend the evidence to any length, did a paper of this sort permit, in order to prove that humidity is favourable to the consumptive patient. It appears singular to me why medical practitioners can so generally entertain a contrary opinion. They have all seen that ague and consumption rarely occupy the same district, but still they are fearful, as it were, of inquiring into the cause, lest it should alter an old-established, popular, and favourite opinion. Ague is the daughter of humidity, and to use the words of Dr. Marshall, of Lynn, she "will bear no brother near the throne," but over consumption she rides rough-shod. In proof of this I could bring forward hundreds of witnesses. In Minorca, for instance, Cleghorn says ague is considered as endemic, and there consumption is rare. In Egypt consumption seldom occurs—there intermittents are common. Volney tells us that consumptive patients are frequently sent to the sea coast, where intermittents prevail. In Bengal, an aguish country, consumption is rare.

PROGRESS OF FRENCH SCIENCE.

(FROM OUR OWN CORRESPONDENT.)

Paris, July 17, 1845.

On Accidental Retraction of the Limbs, by Dr. Morel Lavallée (continued)—*Treatment.*—The therapeutical measures employed in this disease may be classed under two heads: 1. Those which act on the primary affection, of which retraction is the symptom or consequence; 2. Those which act on the retraction itself.

1. *Remedies which act on the Disease, causing the Retraction.*—They are in general prophylactic, and are (*a*) *medical*, and therefore foreign to our subject, for who would think, while describing accidental retractions of the limbs, of enumerating the best means of cure for meningitis, myelitis, nervous convulsions, &c.; (*b*) *surgical*—these consist in preventing the parts surrounding the diseased articulation from contracting a false position, and in preventing, from its very commencement, the retraction which sometimes follows fractures, white swellings, &c. In coxalgia a permanent extension of the affected limb offers two advantages—the one of alleviating pain, the other of combating the muscular retraction which the luxation consequent on disease of the hip may produce. In chronic arthritis, by keeping the leg extended, the retraction of the flexor muscles, and the displacement of the tibia backwards on the femur, are prevented. This method Dr. Jobert de Lamballe, at my request, has had the kindness to try on a patient affected with synovitis of the elbow-joint, complicated with retraction of the biceps.

Case.—Alexander Guyot, ætat. 19, of lymphatic constitution; has never suffered from glandular swellings or rheumatism, though his employment (a baker) subjected him to frequent transitions from heat to cold. About a year ago, a dull pain in the bend of the arm, on the right side, first appeared, noticed only when the arm was considerably extended. A month after this, the patient became affected with chancres, for which he entered Dr. Ricord's ward (Hôpital du Midi); whilst there the pain in the elbow increased, and was accompanied by retraction of the biceps, but both yielded to an active antiphlogistic treatment, and Guyot returned home six weeks after quite well. This amelioration was but temporary, for the pain and the retraction soon returned, and increased gradually, until the limb presented the following state:—fore-arm bent at an obtuse angle; tendon of the biceps not only easily felt, but likewise very apparent; when touched it appeared to be formed of strong parallel cords, and when forcible extension was made, it formed a considerable projection, and produced near its inferior extremity at the bend of the arm a hollow space, deeper than on the opposite side. Sometimes the fore-arm remains motionless at a right angle, and when the patient endeavours to stretch the limb, a sharp noise is heard in the joint. This noise is at times produced by pronation and supination, and is easily obtained by the least external force, being somewhat similar to that caused when the articulations of the fingers are stretched. The brachialis anticus does not participate in the retraction, as it remains uncontracted under the cord presented by the biceps; the fold of the arm is painful on pressure, especially inside the tendon of the biceps; the two furrows which exist on each side of the olecranon in the normal state are replaced by two elongated, soft, semi-fluctuating tumours—the inner one the most apparent; in other respects, the articulation appears neither tumefied nor disfigured. Is not this affection (synovitis) complicated with retraction of the biceps? The cause of this contraction is worthy of notice. Is it not remarkable that the biceps should be affected so as to limit a movement—extension—which, when carried to its utmost extent, causes pain? May it not be concluded, that instinct produces this contraction in the muscles before it becomes organic, and that far oftener than is generally supposed? Dr. Jobert de Lamballe ordered gradual extension to be performed by means of an apparatus, but in so doing, what was the end in view? In the first place, doubtless, to keep the articulation motionless, facilitating thus the resolution of the arthritis, and to restore gradually and insensibly the biceps to its normal length. In the retraction produced by syphilis, the cause must be combated, and it is the only form which yields, when once established, to indirect means. The iodide of potassium may be prescribed, at the dose of ℈ijss per diem, in a quart of tisane of decoct. saponar. offic. or infus. humul. lupul., the quantity being gradually increased to ʒiss, and even ʒij, or ℈vij. It may likewise be administered as follows:—℞. Potass. iodid. ℥ij, Syrup. simpl. ℔ij, Cochl. magn. i, ter in die sumend., sensim augeatur dosis ad cochl. magn. quatuor ter. in die.[1] This mode of treatment has constantly succeeded with Dr. Ricord, who, among other cures, quotes one of an actor at the Italian Opera, who, while singing, was obliged to keep his hand constantly on his hip, the disease being seated in the articulation of the elbow—a part which it ordinarily, if not exclusively, affects. Should secondary symptoms of syphilis exist, the proto-iodurct of mercury must be given at the same time.

2. *Remedies which act directly on the Retraction.*—These are curative or palliative, the simple mention of the latter, applicable only to the lower limbs, is sufficient; as to the former they are mechanical or operative, that is to say, they consist in elongating the shortened tissues by appropriate apparatus, or dividing them with an instrument. Though in reality both are applicable to retractions of the muscles, and normal or accidental fibrous tissues, still when employed in cicatrices their mode of action is so different that they deserve a special paragraph; the curative means of the two former will therefore first be considered.

A. *Mechanical Means.*—In general all the muscular and normal fibrous retractions may in every stage be successfully treated by mechanical means, which should always be had recourse to in recently and slightly developed cases. In these, by gradual traction the part must be brought into its normal position, and kept thus by a bandage and splint, and the cure may be effected as in the following case, where the retraction was seated in the biceps brachialis. Charles Edward Seliza, aged fifteen, upholsterer, of good constitution, and perfect health, having a small column to remove, seized it with both hands, and strove to pull it down by shaking it violently and drawing it towards him; while exerting himself thus he felt in the anterior portion and bend of the right arm a violent pain, which forced him to leave off work for several days; the day after extension became impossible, and the retraction persisted, though the pain disappeared. The lad resumed his labour, but finding that his arm did not regain its normal position, he entered the wards of Dr. Jobert de Lamballe on the 11th of February, 1845, three weeks after the accident. The arm could not be extended beyond an obtuse angle of 110°; neither the arm nor the elbow was swollen; no pain when quiet, but it was developed with considerable intensity at the bend of the arm and in the direction of the biceps as soon as the limb was forcibly extended, and at the same time the fleshy part of the biceps and its tendon presented a considerable projection, indicating evidently that it was the sole cause of the retraction. A splint properly padded was placed on the inside of the arm, and a bandage over it, which was tightened, so that on the third day extension was complete: the apparatus was kept *in situ* for five days, and the patient did not leave the hospital until it was certain that the retraction would not re-appear, and that the cure was perfect. This case, communicated to me by M. Bidault, interne of Dr. Jobert de Lamballe, is interesting not only on account of the rapid success of the treatment (completed in eight days), but likewise owing to the retraction having been produced by a cause which hitherto was supposed to act only on the fibrous tissues. In fact, as the disease appeared after a powerful effort made by the muscle, it cannot be doubted that some injury to this was the cause of the affection.

If the disease manifest itself under the influence of a local affection of which traces are still present, in order to obtain a cure, topical emollient, or other appropriate remedies, must be had recourse to. It is thus that in retractions which originate in hysterical affections Dr. Recamier employs as a secondary or even as a principal remedy, shampooing, or percussion in cadence, repeated as often as the irritation produced by the previous operation has subsided, until the cure is complete. But it is not in recent retractions only that bandages effect a cure, but even in some cases of club-foot itself, as may be seen in a case which occurred in the wards of Professor Gerdy. The starch bandage may here be of great use, because it does not change its position, or become slack to any considerable extent, and because the hollow spaces formed by compression between it may easily be filled up, in addition to which it permits the patient to move about. It must not however be forgotten that the part must be kept in its normal position until the apparatus is quite dry. These bandages often suffice, and therefore ought to be employed, yet it must be confessed that orthopedic apparatus, indispensable in serious cases, is in all of more easy application, and the extension being gradual, spares the patient much pain; moreover, they leave bare a considerable portion of the limb, which is useful, inasmuch as it enables the surgeon to judge of the state of hidden parts. Besides which—and this is very essential—as extension may be performed by the simple turn of a screw, very slight exertion is requisite, and greater effect is produced with less pain. It is here that we may say with Dr. Malgaigne, "Simple means are preferable to complicated, only when they are equally efficacious." It is unnecessary to describe the various machines as they may be seen; but the principles which ought to be followed in making and in applying them must be indicated. As far as concerns the adjustment and mechanism of the various parts of the apparatus it is the province of the manufacturer; the surgeon has only to examine the conditions they should present, so as not to injure the organs, and so as to produce the least possible disturbance during their application: it is this that will be examined under the head, "Rules for exercising *pressure*," after which the different modes of employing them, the time they ought to be kept on, the accidents which they may produce, and the means of combating these accidents, will be studied.

Adhesion of the Pericardium to the Heart.—A curious case of this affection, which was studied in 1844 by Dr. Aran in a Memoir (*Recherches sur les adherences générales du péricarde, nouveau moyen de reconnaître cette affection,*) inserted in the *Archives de Medecine*, has just been observed in the wards of Professor Laveran, at the hospital of Val de Grace. In this memoir are examined, 1. The *causes*; acute, terminating in chronic pericarditis when neglected, badly treated, or developed under unfavourable circumstances; *pericarditis chronic* from the commencement. 2. *Mode of formation*: after acute pericarditis an exudation of plastic lymph takes place, and forms a pseudo-membrane, which is absorbed very slowly; now, if an exacerbation comes on ere this is obtained, a fresh quantity of lymph is exuded, rendering the previous portion still more difficult of absorption; finally, if these relapses are frequently repeated, the pseudo-membranes, instead of disappearing, are organised, and the visceral and parietal portions of the pericardium unite to a greater or less extent. The adhesions present in these cases two aspects: (*a*) by continuance of the phlegmasia they are infiltrated here and there with pus, or rather with a sero-sanguinolent liquid; (*b*) they are formed of delicate and compact whitish cellular tissue. 3. *Symptoms*: Laennec and Professor Bouillaud state that it may exist without producing any notable disturbance; on the other hand, Lancisi, Vieussens, Meckel, Haller, Senac, Corvisart, and especially Morgagni, say that its presence is incompatible with health. Dr. Aran accounts for this difference of opinion by a difference of the lesions, the adhesion in some being cases *cellular*, whereas in others there were *traces of inflammation, and the heart itself was diseased*, and that it is only in the last, that is to say, in cardo-pericarditis, that symptoms and pathological lesions of the heart are observed; of the former, generally complicated with hypertrophy of the walls and enlargement of the cavities, caused, according to Dr. Beau, by the traction exercised on the heart by false membranes, and by the efforts the organ is obliged to make to overcome this difficulty; and, according to Haller (opinion adopted by Dr. Aran), because the heart is incapable of emptying itself entirely. The symptoms are palpitations from time to time, tendency to plethora and congestion, dyspnœa on performing any active exercise. The symptoms of cardo-pericarditis are excessive dyspnœa, palpitations on the slightest movement, considerable uneasiness in the precordial region; weak, tremulous, often irregular pulse, frequent fatiguing cough, accompanied by sanguinolent sputa; œdema, and death in the greatest agony. But other symptoms have been described as characteristic; thus, according to Sanders, there is a sort of hollow spot in the epigastric region, immediately under the left false ribs, produced during the ventricular systole, which he attributes to the retraction of the diaphragm each time the heart ascends; Dr. Hope says that the heart beats higher, a fact which, though at variance with the hypertrophied condition of the organ, is produced by the adhesions, which allow it little motion; the existence of a species of shock or agitation communicated to the thoracic parietes by the efforts made by the heart to overcome the obstacle; the previous existence of pericarditis, especially of a rheumatic nature; the cessation of the friction sound; the non-augmentation of the matity; the violent rebounding movements, sometimes simple, sometimes double, of the heart. Dr. Aran, in addition to the foregoing symptoms, states that the cessation of the friction sound takes place rapidly, in twenty-four or thirty-six hours after it has been heard at its maximum of intensity. But, as this judicious observer remarks, these are not the symptoms of the disease when established, but of

[1] *Bulletin de Therapeutique*, vol. xxii. p. 65; *Gazette Medicale*, 1842, pp. 395 and 544; *Gazette des Hopitaux*, 1842, loc. cit.

the affection about to be formed. The following, according to this author, is pathognomonic; viz., the weakening or the more or less complete extinction of the beating of the heart; the first, or dull sound (bruit de tic) is short, the interval long; the second, or clear sound (bruit de tac) is very feeble, or absent altogether. These last have been said to arise from insufficiency of the semilunar valves, but in such cases the sound is heard when the stethoscope is placed a few lines from the precordial region, and it is always replaced by a very long and sometimes musical bellows sound.

Case.—M. Soldier, ætat. 41, in February, 1843, had been affected with pains in the lower extremities, for which he was bled freely; when received at Val de Grace on the 24th July, 1844, he was inscribed on the list of patients suffering from an affection of the valves: the pulse was irregular; bellows-sound inferiorly during the first beat of the heart. After remaining some time in the hospital he at length left it, but returned on the 11th March, 1845, and stated that he had been constantly ailing, that his breath was short, and he was subject to palpitations, and that his lower limbs swelled on the least exertion. On examination he was found to be in the following condition: vinous tint of the face; œdema around the malleoli; abdomen tumefied; decubitus on the right side; 20 inspirations in the minute; pulse small, irregular, 60; *lower part of the precordial region is the seat of an elevation of the skin every time the apex of the heart is raised*; matity to the extent of about three or four inches; impulsion of the heart powerful; beating irregular; what was more extraordinary was the mixture of the two sounds, which could not be distinguished separately, or, to speak more correctly, the second was wanting; the first appeared to some to be accompanied by a bellows-sound; matity on the right side; ægophony; dull sound in the lower parts of the abdomen; urine scanty and high coloured. Diagnosis. —General adhesion of the pericardium to the heart; hypertrophy of that organ; lesion of the valves; effusion in the pleura and peritoneum. The patient was bled several times, temporary blisters were applied on the region of the heart, but without any beneficial result; the symptoms became more and more intense; nocturnal dyspnœa; considerable anasarca; anorexia; constipation, and the patient became sad and discouraged. On the 12th paracentesis was performed to relieve the oppression, but the relief was but momentary, for soon after rigors occurred which lasted until death took place on the 13th. Autopsy.—Right pleura red, thick, and covered with pseudo-membrane, and containing about ten ounces of serosity; a small quantity was likewise found in the right pleura; venous congestion of the lungs. Heart of considerable size; from six to six and a quarter inches in length, and of equal breadth; cavity of the pericardium no longer existed, the two surfaces being closely united. It was only after a very careful dissection that they could be separated. 1. The parietal layer covered with uneven pseudo-membranes, the whole being about two lines thick. 2. A layer, equally thick, fibrinous, red, uneven, and almost muscular in its aspect. 3. The visceral layer also thickened, and covered with a few remains of the fleshy pseudo-membrane which separated it from the former. Deprived of this treble envelope, the heart was not more than four inches and a half in size; the left auricle alone was enlarged, its cavity being two inches in length and as much in breadth; substance of the heart of a rose colour, somewhat firmer than in its normal state; nothing remarkable on the right side of the heart, on the contrary, the left offered— 1. An eccentric hypertrophy of the auricle, the walls of which were about a line thick. 2. Simple hypertrophy of the ventricle, the walls of which in their central portion were about nine lines in thickness. 3. A double lesion of the valves; (*a*) mitral valve with its fleshy columns was fibro-cartilaginous, and formed towards the interior of the ventricle a sort of retracted funnel, but still performed its functions; (*b*) aortic orifice diminished by the fibrous induration of the semilunar valves, which were insufficient in width. Liver hypertrophied, surface uneven and mammillated; interior of a granular aspect; soft. Stomach presented numerous superficial ulcerations. *Gazette des Hopitaux.*

Academy of Sciences; Sitting of the 14th July. M. Elie de Beaumont in the chair.

On vesico-vaginal Fistula, by Dr. Jobert de Lamballe, M. A. M., &c.—The permanent and perfect cure of this disease is not sufficiently frequent by the present means to prevent a new treatment being worthy the attention of the Academy. All surgeons are aware how difficult is the reunion of the divided parts in this affection; so much so, that any method by which this result may be facilitated will not fail to be attended to. A woman was received at St. Louis with a vesico-vaginal fistula, caused by parturition; the urethra was completely destroyed, and the loss of substance, which was seated in the septum vesico-vaginalis, extended inwards, on the mesial line, to about half an inch from the cervix uteri; there existed, consequently, a large cloaca, into which the urine fell ere it escaped from the vulva. Several modes of treatment were employed; among others, the autoplastic method, which was communicated to the Academy some years ago, but without success; and the patient left the hospital very little better than when she entered. A year after she came back, and, on the 9th of June, 1845, the following operation was performed (which the author denominates *reunion autoplastic par glissement*):—a transversal, semi-circular incision was made on the anterior portion of the neck of the uterus, where it joins the vagina; the flap thus obtained was dissected from below upwards, the edge of the bistoury being constantly directed towards the uterus, to avoid wounding the bladder; immediately after this incision and dissection, by which the fundus of the bladder was isolated, the anterior portion of the vagina was drawn inwards, and a change of position of the posterior region of the bladder, by which the edges of the part could be placed in contact and kept united, and the loss of substance repaired with great facility, even when considerable, as in the present instance, thus effected. The patient, whose case has been just related, is at present in the following condition:—1. There is at the upper extremity of the vagina a thick and solid cicatrix, which supports the bladder. 2. In front of the cervix uteri there is a swelling caused by the bladder and the upper part of the vagina, which are detached from the cervix. 3. There is a furrow directed from before backwards, indicating the spot in which the two edges of the fistula were united. 4. Before this furrow, and at the spot corresponding to the neck of the bladder in the normal state, there is a small opening into which a catheter can be passed. 5. The urethra no longer exists, but the newly-formed vesical orifice seems to perform its functions perfectly. 6. The urine can be retained several hours, the patient feels the desire of evacuating it, and effects this at will. 7. When the patient moves about, the urine is not so easily or perfectly retained. The author concludes by stating, that this case will form the subject of a memoir which is shortly to be presented to the Academy.

On the Endemic Diseases developed periodically under the Influence of Marsh Miasmata. By C. A. Ancelon, M.D.—The author in this memoir studies the pathological conditions which return at stated periods, and which present constantly the same mode of development, the same symptoms, and the same characters, and which are endemic in the neighbourhood of the immense pond, or rather lake, of *Indre Basse*, emptied and cultivated every third year. These diseases are—1. *Typhoid fever*, present during the second year; observed as an epidemic in 1830-33-36-39-42. Its *causes* are—decomposition of vegetable substances during the hot weather; filthy state of the villages; badly built cottages, the floors being lower than the ground outside, the doors and windows not sufficient for free ventilation; crowding many individuals in too small a space; action of the sun's rays on the peasants while at work in the fields; use of brackish water; insufficient food. It is not contagious, and its frequency is in direct ratio with age—childhood excepted. It appears towards the end of June, in July, and August, and disappears, if the temperature decreases, during these months; when prevalent, it gives its stamp to every other disease, and even puerperal fever itself is converted into dothinenteritis. In addition to the usual signs there is tremor of the limbs, which in some patients goes so far as to imitate epilepsy; a parchment-like skin; pain in the muscles, with an affection of the ganglionic nervous system. Treatment—tonics internally and externally, decoction of polygala, Seltzer water; no abstinence from food is requisite. 2. *Intermittent fever* occurs during the first year; observed in 1829-32-35-38-41. During the spring it is at first quotidian, soon followed by tertian, and disappears during the hot months, to begin again in the autumn, when it sometimes assumes the quartan type. If the summer is hot and moist, during autumn, the double tertian is observed, and is with difficulty got rid of; damp, foggy weather makes it assume the catarrhal character, and too much heat, the typhoid. The cold stage of the quotidian is not very marked, that of the tertian lasts sometimes several hours; it is very long in the quartan, and death often takes place on the second attack of the pernicious form. In the variety denominated neuralgic, the shivering fit is replaced by a violent pain in the limbs, or in other parts of the body; the catarrhal form presents no sweating stage, is seldom fatal; relapses are frequent; visceral congestions have diminished considerably in number since the peasantry have been induced to take the sulphate of quinine. The treatment consists in the application of a few leeches, and the administration of quinine, steel, opium, and indigenous bitters; against tumefaction of the spleen, quinine; of other viscera, iodine. 3. *Carbuncular affections* reign the third year; observed in 1831-34-37-40-43; caused by the same emanations, and appear during the months of July, August, and sometimes September. From what precedes, it may be concluded that there is a striking analogy between the three affections just described; that they are produced by the same causes, *marsh miasmata*, which act continually, and give rise to one or the other, according to their intensity, the season of the year, and the hygrometric condition of the atmosphere. It must be added, however, that the periodicity of these diseases is in a great measure, if not altogether, owing to the mode adopted in working the pond.

Academy of Medicine; Sitting of the 15th July. M. Caventou in the chair.

On Fibrous Tumours.—Dr. Londe, M.A.M., re , in the name of Professor Le Sauvage, of Caen, a memoir on Albumino-Gelatinous Tumours. In the opinion of the author, individuals who have made pathological anatomy the object of their studies, do not pay sufficient attention to the distinction between two species of tumours; the one species produced, in most organs, by intussusception, never extends beyond these organs; the other results from the transformation of the normal tissues; and it is for this reason pathologists are not aware of the practical applications these divisions lead to, nor have they any precise ideas on fibrous tumours. The diagnosis may notwithstanding be easily established: 1. by the size they attain; 2. by the equality of their surfaces; 3. by their mobility; 4. by the absence of pain in their structure; 5. by an apparent fluctuation; 6. by the integrity of the skin covering them; 7. by the normal state of the lymphatic glands; finally, the author explains why tumours offering but an apparent analogy with those described in the memoir, were supposed to be fibrous, and states that albumino-gelatinous tumours may be removed without any danger of relapse.

Nomination of Foreign Associates.—The Academy proceeded, by ballot, to name eight foreign associates; 78 votes—majority 39. The following gentlemen having obtained the majority, were declared elected: Messrs. Burdach, Kœnigsburgh, 70; Muller, Berlin, 63; Liebig, Giessen, 60; Brodie, London, 50; Lawrence, London, 43. The nomination of the three others was postponed until the next Sitting.

On Typhoid Fever.—Dr. Louis read a report on a memoir presented by Dr. Jacques, of Lure (Haute Saone) on several epidemics of typhoid fever observed in the arrondissement of Luri. This memoir is of considerable length, carefully elaborate, and worthy of the attention of the Academy. It is divided into three parts: in the first, the description of twenty-five cases of sporadic typhoid fever is given; the second contains that of the epidemics of typhoid fever observed in several villages; and in the third, by means of facts observed by himself or communicated by others, the causes, the diagnosis, the prognosis, and the treatment are examined.

Among the predisposing causes are: Age.—From a statistical table by the author it would appear, that before ten the predisposition is less than from fifty to sixty. Several cases are recorded of persons upwards of sixty, and one upwards of seventy. The learned reporter expresses his doubts as to the correctness of these facts, which are so different from what is daily seen at Paris; he is led to believe that as all the cases analysed did not fall under the author's immediate observation, there was an error of diagnosis; for it can hardly be admitted that so many old persons could have escaped so long, and if on the contrary, it was supposed that they had been previously attacked, it would be allowing that typhoid fever frequently occurs twice, which is more than doubtful. Sex, intemperance, change of diet and habit, seemed to have no effect. Determining causes; seasons, barometrical changes, and localities, possess no positive influence. Habitation.—From the facts recorded it would appear, that unhealthy, badly-ventilated rooms, and especially when too small for the number of persons, may give rise to it. Marshes do not possess the preservative qualities of late attributed to them; on the contrary, in general the villages in which intermittent fever reigns present more patients than others. Burial-grounds, contrary to the opinion of many writers, seem to have no effects. Contagion.—The opinion of Dr. Britonneau and other practitioners is confirmed by the fact, recorded by Dr. Jacques, that almost always when typhoid fever invades a locality, it is communicated by the patients to those who take care of them, and come to see them, and when once it enters a house it does not leave it until it has attacked all who are susceptible of its influence, and it was very uncommon to see the inhabitants of the same house affected at periods separated by an interval of fifteen or twenty days. Assuredly the disease is contagious, but not to such a degree as to be propagated by simple contact, besides which the contagious principle is not so active in slight as in serious cases, nor in those persons by whom the rules of hygenic are attended to, as in those by whom they are neglected. Moreover, more individuals than is usually supposed are incapable of contracting the disease; many have been previously affected without being aware of it, and if in large towns contagion is less evident than in small localities, it is because hygienic rules are better known, and the communication between the healthy and the sick is not so frequent. It may, however, be affirmed, said the reporter, that authentic cases leave no doubt of the propagation of the disease in large towns, by contagion, and among the most conclusive may be placed those quoted by Dr. Gaultier de Claubry at a previous meeting. Again, how is it possible that a disease should be contagious at Tours and not in Paris? Relapses.—According to the author they are not infrequent, but the facts on which this opinion is founded are far from conclusive; they are sometimes observed, the proof of which is the following case: a young man, aged fifteen, tall, general health good; was affected in January, 1812, with typhoid fever, which yielded only after twenty days; in April, 1843, he experienced a second attack, which lasted as long as the first, and was just as severe. No doubt can be raised as to the reality of the latter, as it occurred while the disease reigned as an epidemic in Paris. Treatment—Prophylactic—consists in isolating the sick in large and well ventilated rooms. Remedial. Here the author passes in review venesection, purgatives, and emetics, preferring the two last; opium is useful when ataxic symptoms exist, but he only mentions the remedies without stating how and when they ought specially to be employed. He is, however, more explicit while speaking of the application of cold to the skin, for he examines the question minutely, points out the indications and counter-indications, studies its action in fatal cases and on several symptoms of the disease, and concludes, that cold lotions are not very energetic; that affusions and baths present difficulties; that the best mode is the application of a towel dipped in water at about 45° or 50° F., on the abdomen and forehead, renewed every quarter, or every half-hour; that it may be applied to other parts of the surface of the body; that it is preferable to ice, which is painful, supported with difficulty, and increases the delirium it is meant to combat; that with the exception of a notable diminution in the temperature (very uncommon in typhoid fever) no symptoms, no complications counter-indicate cold applications or cold drinks—that even the lesions of the respiratory organs are not aggravated by them. Dr. Louis, after examining this method and the facts recorded in its favour, terminates thus: "If the committee pay such attention to this subject, it is because the members forming it are desirous of forming a positive opinion, and of convincing the Academy of its correctness; the more so, as the talent of the author renders his assertions worthy of attention. This examination did not lead them to adopt the conclusion of the author, for the cold applications were not made regularly, and when thus applied, it was only for a few days; the future will perhaps confirm the author's assertions, but more facts are necessary ere they can be received as truths, for it is difficult to determine the efficacy of an incomplete treatment, or of one employed but for a short time. The committee, notwithstanding, persist in the opinion announced in the commencement of the report, and consider the author to be a learned and clever practitioner, whose advice may be useful to the authorities and the inhabitants of the country in which he practises, and, consequently, propose—1. To address a letter of thanks to the author for his memoirs. 2. To advise his continuing his researches in the way hitherto adopted. 3. To add his name to the list of future national correspondents, of which he will be one of the most enlightened and most worthy. Dr. Rochoux considered the memoir to be founded on an erroneous diagnosis, and could not admit a disease to be sometimes contagious and sometimes not. Dr. Louis: Though there may be some errors of diagnosis, still that is no reason why the whole memoir should be erroneous; as to contagion, Drs. Bretonneau, Gaudron, and many others, had recorded facts, and he himself had witnessed four undoubted cases. Dr. Honoré accepts as correct the case recorded on contagion, but considers the fact as far from being proved in Paris, and therefore says it ought not to be given as a maxim. Professor Piorry considers it not so easy to diagnosticate typhoid fever as supposed; that to accomplish this with any certainty, the practitioner must attend not to the fever, but to the pathological state of the organs, the degree of gravity, and the complications; and that as long as the generic term of typhoid fever is employed, statistical tables will be useless. Dr. Louis thinks that from the third to the seventh day typhoid fever may be diagnosticated as easily as any other affection. Professor Gerdy: Two conditions are necessary in order that a disease may be communicated—a contagious property, and a peculiar individual susceptibility—which explains why sometimes it is propagated, sometimes not. After some further remarks from Drs. Castel and Rochoux, the conclusions were adopted.

Garland de Beaumont, D.M.P., B.L., & S., &c.,
Honorary Physician to the Spanish Embassy.

PROGRESS OF GERMAN MEDICAL SCIENCE.

By Sigismund Sutro, M.D.

Recovery from apparent death by cold; remarkable effect of birch-tar.—The body of a man, ætat. 45, was discovered, perfectly stiff and cold, but not entirely frozen; his mouth could not be opened by any means; no sign of respiration or arterial action could be detected. After the body had been softened by frictions with snow, rags dipped in cold water, and woollen cloths, the lungs were inflated, and clysters of tobacco were administered without effect; as a last resort, the author placed the body on a straw mattress, with the head raised, and ordered the sexual organs, particularly the scrotum and perinæum, to be well rubbed with birch-oil, when very soon a sound like bleating was heard; and after the frictions had been extended to the abdomen and upper parts of the vertebral column, further signs of life appeared. He was then laid in a warm bed, where he soon recovered his senses, and fell into a sound, healthy sleep. The birch-oil is very much used in Russia as a domestic remedy, both to sober drunken people and to cause them to dislike spirituous liquors. In both cases the sexual organs are rubbed with it, and a violent headache is said to arise, which lasts for a day or two. It is also taken internally, as a popular remedy for dropsy and rheumatism.—*Dr. Kostroff in Medic. Zeitung Russlands.*

On the use of some artificial mineral waters.—Soda water, containing in twenty-four ounces—

Carbonate of soda . .	90 grains
Chloride of soda . .	30 „
Carbonic acid gas . .	23·35 cub. inches

was used with great success by the author in acidity of the secreting organs and in uric acid concretions; also, in scrofula, particularly mesenteric tabes; in gout and venous congestion; in hemorrhoids with abdominal congestion; in hypochondriasis and hysteria. The dose is from twelve to twenty-four ounces.

Iodide of sodium mineral water, containing in twenty-four ounces—

Carbonate of soda . .	23·10 grains
Sulphate of soda . .	·84 „
Muriate . . .	24·42 „
Phosphate . . .	1·08 „
Carbonate of magnesia .	2·38 „
Carbonate of lime . .	2·78 „
Carbonate of protoxide of iron	·22 „
Silica	·42 „
Iodide of sodium . .	1· „
Carbonic acid gas . .	23·35 cub. inches

The author has used it with great advantage in old and obstinate cases of struma, and has found it even act beneficially on the digestive process; in herpetic exanthemata, in fluor albus, in dropsy from abdominal atony, or hepatic obstruction, it may also be used with good effects.

Iodide of iron mineral water, containing, in twenty-four ounces—

Carbonate of soda . .	27·90 grains
Sulphate of soda . .	0·84 „
Muriate of soda . .	32·10 „
Phosphate of soda . .	1·08 „
Carbonate of lime . .	2·78 „
Carbonate of magnesia .	2·38 „
Carbonate of protoxide of iron	0·50 „
Iodide of sodium . .	0·10 „
Carbonic acid gas . .	23·57 cub. inches

particularly recommended in atonic scrofula, torpid gout, pituitous catarrh, atonic hemorrhoids, chlorosis with deficient menstruation, leucorrhœa, and atonic urinary diseases.

The simple carbonic bitter water of Saidschütz, containing, in twenty-four ounces—

Sulphate of magnesia .	62·37 grains
Nitrate of magnesia .	5·92 „
Muriate of magnesia .	11·22 „
Carbonate of magnesia .	0·82 „
Sulphate of potash . .	2·40 „
Sulphate of soda . .	17·62 „
Sulphate of lime . .	1·13 „
Carbonate of lime . .	5·10 „
Silica	96·67 „
Carbonic acid gas . .	15 cubic inches

The double carbonic bitter water of Saidschütz, containing, in twenty-four ounces—

Sulphate of magnesia .	124·75 grains
Nitrate of magnesia . .	11·65 „
Muriate of magnesia .	2·43 „
Carbonate of magnesia .	1·63 „
Sulphate of potash . .	4·80 „
Sulphate of soda . .	38·23 „
Sulphate of lime . .	2·25 „
Carbonate of lime . .	10·20 „
Carbonate of strontia .	0·06 „
Carbonate of protoxide of iron	0·02 „
Peroxide of manganese .	0·01 „
Silica	0·18 „
Subphosphate of lime and argilla	0·03 „
Carbonic acid gas . .	15 cubic inches

Both have rendered excellent services in abdominal obstructions from torpidity, venous congestions, hypochondriasis, hysteria, icterus, and melæna; from one to two glasses a day are sufficient. In an irritable state of the digestive organs, the natural water of Saidschütz should be preferred,

because it does not contain any free carbonic acid. The author frequently administers the artificial water of Saidschütz, with Selters water, in the following manner: half a glass of the former to be succeeded by a glassful of the latter, particularly to those patients with whom Selters water does not act with sufficient power, and the Saidschütz water alone exerts too violent effects.—(*Professor Warber of Freiburg, in Szerlecki's Journal for Therapia and Pharmacodynamic.*)

On frontal and temporal Neuralgia.—The external application of croton oil has the great disadvantages of spreading in its effects beyond the place of application, and of causing a disagreeable eruption. This disadvantage can be avoided, and the same effects produced by the application of Ol. cort. hyoscyam. with one grain of acetate of morphia, in the following manner:—A mustard poultice, prepared with cold water, is applied over the situation of the pain, and allowed to remain for an hour; frictions with the above oil are then repeated every two hours. The mustard-poultice is reapplied on the following day, according to circumstances. From four to five applications are generally sufficient to cure the most obstinate neuralgia. —(*Dr. Puppi in Asterr. Medic. Wochenschrift.*)

Treatment of Hypertrophy of the Heart.—The author gives his opinion against the usual method of treatment by blood-letting in hypertrophy of the heart. The hypertrophy causes a disturbance of the bodily equilibrium, and the whole body becomes emaciated, whilst the functions and dimensions of the heart increase. The frame ought rather to be strengthened by a mild nourishing diet, and every excitement avoided. The inutility of fox-glove need not be expatiated upon, since it is generally acknowledged; nor do the combinations of iodine counteract the cardiac hypertrophy; besides, they are frequently contraindicated by bronchial catarrh, cerebral congestion, &c. The author recommends mercury in the form of proto-ioduret (mercur. iodat. flavus) till severe salivation be induced. The patients must remain in bed, be well covered, and take diaphoretic drinks and purgatives. The fibrine of the blood is diminished by the above treatment, and the muscular tissue altered. The author never perceived vascular excitement ensue from the treatment he recommends, in proof of which he narrates five cases. (*Dr. Gottschall, of Cologne, in Casper's Wochenschrift.*)

Enormous Hypertrophy of the Spleen.—Dr. Steinbeck observed an enormous hypertrophy and induration of the spleen in a weak country woman, who had frequently suffered during the last ten years from paroxysms of fever, which she used to suppress by fever powders. A hard and unpainful swelling was perceived in the region of the spleen, becoming more and more distinct by the patient's emaciation, which constantly increased. The author first ordered solvent extracts with purgatives internally, and emollient cataplasms, and afterwards emplastr. cicutæ externally. As this treatment, with muriate of ammonia and tartrate of antimony, produced no effects, he ordered iodine externally and internally; within a week a diminution of the tumour was perceptible, and after three weeks the swelling could scarcely be perceived. The hardness of the spleen could only be felt on pressure. The patient continued the use of the iodine, and ultimately took iodide of iron, which caused a great improvement, and restored her to perfect health.—(*Preuss. Ver. Zeitung.*)

On the Resorption of Pus.—The author communicates the following case to contest the views of those who think the resorption of pus impossible, on account of disproportion of the pus-globules to the capillary vessels. On examining the body of a soldier, who died of anthrax, a little thin, brownish-red blood was found in the heart, which caused a pricking sensation when handled. The microscopic investigation showed besides blood-corpuscles a considerable quantity of granulated globules, which bore all the signs of pus-globules, becoming transparent when treated with acetic acid, causing nipple-shaped nuclei to appear. Their bulk in proportion to that of the blood-corpuscles stood as one to eight; at the same time, the kidneys had degenerated into a soft, homogeneous, yellowish-red mass, containing blood-corpuscles, pus-globules, and cells. Abscesses of the lungs were also present, and a putrescent state of the whole mass of blood was apparent. The author is undecided whether to think that the pus-globules adapt themselves to the mouths of the capillary vessels by a peculiar inherent power, and thus enter into the circulation; or, that they are first resolved into their constituents, and then reformed in the blood.—(*Dr. Muhlbauer in Allgemeine Zeitung f. Chirurgie.*)

PROGRESS OF IRISH MEDICAL SCIENCE.

(FROM OUR OWN CORRESPONDENT.)

Dublin, July 26.

Cases of Apoplexy; treated by J. Moore Neligan, Esq., M.D., Physician to Jervis Street Hospital; with Clinical Observations.

James O'Neil, admitted July 7, a labourer, aged 36, while at work on the 26th of June, became suddenly giddy, and fell in a state of insensibility, from which he shortly recovered, and then resumed his labour; he had a similar attack in the evening, after which he returned home, and was bled and freely purged on the same night. In the course of the three following days, during which he did not return to his work, he had gradual loss of motion in the right arm, and this had so much increased on the fourth day as to have rendered the limb completely useless. Paralysis of the muscles of the right side of the face also ensued, but not of those of the tongue; there was difficulty of articulation, in consequence of which in speaking he omitted many words. The right leg was affected to a very slight degree. He is a man of robust constitution and sanguineous temperament; states that he has been all his life remarkably healthy; never had any disease of the chest or palpitation of the heart.

On admission with the above symptoms of paralysis, the pulse was full and incompressible, about 65 in the minute; the chest sounds normal on percussion, except the region of the heart, an increased space over which was dull, and a loud bruit de soufflet was heard to accompany its first sound. The secretions of the bowels and kidneys perfectly normal. Ordered cupping to the amount of ℥xvj. from the back of the neck, and a purgative bolus.

8.—Bowels frequently acted on since yesterday; speaks a little more distinctly to-day, and now also has slight power of motion in the fingers of the right hand.

℞. Calomel gr. xii, Pulv. Jacobi ver. ʒss. in pulv. xij, divid. sumat; mane nocteque.

10.—Pulse 84, full, and slightly compressible; feels better to-day, with much more power of motion in the fingers of the right hand, and perfect power of motion in the right leg. Articulation continuing to improve; bowels free.

Emp. canth. nuchæ.

Since the above report, he has progressed to almost perfect recovery under the exhibition of gradually increased doses of James's powder; a seton of a few threads was also passed through the back of the neck on the 21st inst.

Clinical Remarks.—I wish to draw your attention, gentlemen, to the case of apoplexy in No. 4, chiefly with the view of offering a few observations on the pathology and the therapeutic indications to be fulfilled in the treatment of this disease.

The very general practice of using the lancet in such cases I think extremely injudicious, yet it is a course so familiar to the public that the friends of a patient call loudly for it, and the young physician who, depending upon his knowledge and experience of the disease, fails to employ it, takes upon himself the onus of the case, and if the patient dies, he is generally blamed for having gone out of the usual course in the treatment. It is, therefore, of great importance to be able to ascertain whether this practice is attended with benefit, or if, on the contrary, it does not too frequently lead to the occurrence of paralysis or death. Copeman, in his recently published selection of cases of apoplexy, enumerates 155 collected by him from the journals and from practice, showing that the proportion of deaths from this mode of treatment is as one to one and a half, while under a different system it is not more than one in three and a quarter, thus speaking decidedly against the bleeding practice in apoplexy. We find that the disease in its mode of attack does not always follow a direct rule; Abercrombie was the first to call attention to the three peculiar forms in which it manifests itself, and his description is, I believe, the most accurate ever published. In the first form, the patient, previously in good health, is suddenly struck down, with loss of sense and motion. You come up to such a case, occurring perhaps in the streets, and you find the person insensible to motion or even shouting and pinching. To this, Abercombie gives the name of primary apoplexy; a form of the disease in which recovery often takes place if it be properly treated. In the next variety of the affection, a person walking about his room suddenly feels giddy, becomes insensible for an instant, his stomach is sick, face deadly pale; but he recovers in a minute or two, and remains well, probably, for five or six hours, at the end of which time he is struck completely insensible, and becomes perfectly comatose. This is a form of the disease which you should accurately bear in mind, for the subjects of it early recover, and you might readily be led into making an improper prognosis, from seeing a patient immediately after a fit, such as I have just described, and finding him apparently in perfect health; but even within ten minutes, says Abercombie, a fit comes on, which he rarely survives.

In the next variety—the paralytic—the individual first loses the power of motion of the muscles of one side of the face, or of one arm, a leg, or of one side of the body perhaps. He may never lose his senses completely—never, in fact, become comatose; this is a case in which the paralysis generally lasts a considerable time, and one, too, very difficult of cure. The case of O'Neil was one of primary apoplexy, the paralysis not having set in for three or four days, which circumstance in itself marks it as belonging to that division, and arising from effusion of blood. The lecturer here showed specimens of the disease in its various forms from Dr. Hope's work, some exhibiting clots in the substance of the brain, or under the pia mater, others in which there was mere congestion, and some exhibiting appearances as if the blood after the lapse of a few months were absorbed.

In Abercrombie's second division of the disease we always have rupture of vessels and consequent effusion, and with the rupture of the vessels there is also laceration of a few fibres of the cerebral substance. The sudden shock produces faintness, loss of motion, &c., closely resembling the apoplexy produced by accident, such as you are accustomed to see in the surgical wards.

In the case under consideration—that of O'Neil—you are aware that the dulness over the region of the heart extended to a greatly increased space, with tumultuous action of that organ, and a bruit accompanying its first sound, which probably extended into the second; this being difficult to decide, however, from the greatly increased action of the heart. The bruit extended along the aorta, and was accompanied with visible pulsation in all the vessels, particularly the carotids. With respect to treatment, I have no doubt that touching the mouth with mercury so as merely to produce slight soreness of the gums with some mercurial fœtor affords the best chance of effecting absorption of the clot; from the moment that O'Neil's gums became affected, the power of the muscles of the arm and face returned. Now, independent of the numerical statement of Copeman as subversive of the treatment by bleeding, all the cases which I myself have seen tend to show that in every instance in which the patient was bled, not during the fit, but some time after, paralysis invariably ensued. In the case of O'Neil it was so. He was bled in the evening of the attack, and gradually increasing paralysis took place in three days after. This fact goes to show that bleeding had no effect in checking the effusion, because we must suppose that, as long as the paralysis continued the effusions also remained. I believe if the lancet be used at all, it should be only during the fit, and then only when there is very marked sanguineous congestion of the brain evidenced by increased action of the carotids, congestion of the vessels of the scalp, &c. With reference to *local* bleeding after recovery from the fit, I have seen much more benefit derived from the use of the cupping glasses than from the application of leeches.

Abercrombie's second form of the disease is al-

most always fatal. Still, I think something may be done, if you are called at an early period between the first attack of mere giddiness and the supervention of coma. I shall read for you the particulars of a case of this sort that occurred in a gentleman under my care some time since.

B——, Esq., ætat. 50, a large plethoric man, of marked sanguineous temperament, while stooping to pick up something from the ground on the morning of the 29th November, 1844, before breakfast, was suddenly attacked with difficulty of enunciation, so that he was himself conscious of a thickness of his speech, and his wife, on seeing him immediately afterwards, perceived that the right angle of his mouth was drawn downwards. I saw him in about half an hour after, when the difficulty of articulation still continued, but there was no distortion of any of the muscles of the face. He did not feel the least pain or giddiness in the head, nor was there any sickness of stomach. The pulse was 84, full, and rather incompressible. There was no turgescence of the blood vessels of the face or of the jugular veins, and no visible pulsation of the temporal arteries. The tongue was foul, and the bowels had not been as free as usual for two three days before. The secretion of urine for twenty-four hours previous to the attack was very copious and of a pale colour. As a naval officer, this gentleman had been exposed during his life to great vicissitudes of temperature, and had resided a good deal in hot climates. He had some slight attacks of gout in his feet about twelve years ago, and also had frequent severe attacks of ophthalmia, but never felt any symptom of determination of blood to the head, or anything resembling apoplectic warnings. He attributes the present affection to anxiety of mind, and to having slept for the last few nights on a feather bed, having been all his life accustomed to sleep on a mattress.

Purgative pills with calomel gr. x were now ordered, to be followed by an aperient draught in two hours after.

At half-past four o'clock of the same day he had had several similar returns, and at that time spoke very thick, and seemed somewhat confused; the bowels had been moved freely; pulse 90, full, and incompressible; face flushed with an uncomfortable feeling in the head, not amounting to actual pain.

Appl. Cucubitulæ nuchæ et detrahatur sanguis ad. ℥xvj.

The feet to be immersed as far as the knees in water as warm as he can bear it, in which mustard, horse-radish, and salt were infused; a stream of cold water was also poured directly over the surface of the head, and a turpentine enema administered. All this was done promptly, but for which I have no doubt my patient must have fallen into coma and died. With respect to the prevention of a return of the fit, the treatment adopted by the late Dr. Cheynes offers the best possible means for the purpose. It consists of small and gradually increased doses of James's powder, and is a remedy, I believe, not much employed out of this city. It may be commenced with doses of two grains at bed-time, with an addition of half a grain every night, until some decided effect is produced upon the system either by diaphoresis, catharsis, or emesis. This was the course of treatment pursued in the case of the gentleman just detailed, whose maximum dose of James's powder arrived at eighteen grains, which was the largest dose given by Cheynes. I have lately heard from this gentleman, who is at present in Liverpool, and he states that he has since had no warning or symptom to make him fear a return of the disease, though, from his time of life, full habit of body, and free mode of living, it might reasonably be expected. His case, I think, exhibits in a very marked manner the good effects of James's powders.

Thus, then, gentlemen, my object in these observations was to impress on you the avoidance of the injudicious employment of blood-letting in the course of an apoplectic attack, and the advantages to be derived from the exhibition of James's powder in preventing a return of the fits.

OBITUARY.—Dr. John Ramsay, on the 8th inst., at Edinburgh: he was formerly of Newcastle-upon-Tyne. Also, William Tudor, Esq., of Bath.

NOTICES TO CORRESPONDENTS.

☞ *Subscribers who are in arrear since Midsummer, are requested obligingly to forward their remittances. By paying in advance for the year, a saving is effected to them, and much trouble about accounts spared us. Our rule is to be paid in advance.*

A Constant Reader *writes:—"As the Medical Bill is postponed this session, I say to the College of Physicians that they should admit Practitioners who have not certificates of so much as three years' medical practice to their extra-licentiateship. That College will thus confer, and also derive benefit, for many would gladly avail themselves of the privilege, and cheerfully undergo any examination to obtain their diploma; whereas gentlemen are now going in swarms to St. Andrew's for a degree which requires merely a diploma of having passed some college. I hope the College of Physicians will not continue blind to their own interests."*

"Surgeon Snipe's Farewell to the College" *is not equal to the merit of his pamphlet. The two first stanzas will excuse our omission of the rest:—*

"Farewell 'Pure!'—and if for ever—
Still for ever, fare thee well—
Even though '*unenfranchised*' never
'Gainst thee shall *my* heart rebel!

"Though the world for this commend thee—
Though it smile upon the blows,
Even its praises must offend thee,
Founded on another's woes."

F. C. B. *writes:—In a recent discussion on pityriasis nigra, one or two of the members were disposed to consider that the colouring matter in acne punctata is composed of pigmentum nigrum. I would ask, how are we to account for the very frequent appearance of this species of acne in persons living in large towns where dust, soot, and minute particles of various other matters are constantly afloat in the atmosphere, while persons residing in rural districts are comparatively free from it? Further, how is it, if the colouring matter be the pigmentum nigrum, that an individual shall leave a populous town a splendid specimen of acne, and after a few weeks' sojourn in the pure air of the country, shall not possess one distinguishing mark?*

Philos (*Brighton*) *asks us for a candid reply we cannot candidly give. The three works are suited to meet different wants; the largest being the best for a person in practice, the smallest for the student. We cannot say more.*

The second paper by Dr. Lewin on the University of Edinburgh will appear in our next.

Mr. G. Wilson *returns this week to the charge. He first belabours us for saying that "it is a small hardship to do a government service for nothing." This is straining our words; we made no such general proposition. We said that a small government service, requiring half an hour's toil per annum, and which could not be remunerated in any reasonable fashion we could think of, was a "small hardship," which, under all the circumstances, was a ridiculous matter to be used as a great grievance. Mr. Wilson, however, who will see nothing in the "hardship" but a grievous wrong, rates us soundly for inconsistency, because, opposed as we are to gratuitous services, we allow of an exception in this case; and insists that thirty thousand medical men could be paid, and should be paid by government for writing the register of the year's deaths. Of course we cannot quarrel with Mr. Wilson for a difference of opinion; but would remind him that there is such a thing as judgment in the selection of a grievance, and that there are occasions when good principles may be stretched too far.* Summum jus, summa injuria.

A Constant Reader *is evidently unaccustomed to write for the press.*

The analysis of S. *will certainly appear.*

The communications on Mr. Gossett are declined.

A Correspondent *complains, that having had occasion to prescribe opium rather largely in a severe case of delirium tremens, his prescription was sent to a druggist, and there made up. Failing to effect the desired purpose, the dose of opium was increased, until 230 grains were exhibited in the course of twenty-four hours. Astonished at this want of success, our correspondent procured from another house a drachm of Battley's liquor opii sedativus, the exhibition of which was followed by nine hours' sound sleep. The inference is plain: the druggist had dishonestly dispensed a very adulterated article, and thus the sufferer's life was endangered by the disgraceful attempt of the druggist to obtain a slight addition to his fair profit.*

A Fellow *is thanked.*

A Member of the College of Surgeons, *and several other correspondents, are unavoidably postponed until next week.*

The continuation of Dr. Clay's paper on Asphyxia, and the paper on Mesmerism by Dr. Warenne, of Hull, shall appear next week.

THE MEDICAL TIMES.

SATURDAY, AUGUST 2, 1845.

Igneus est ollis vigor, et cœlestis origo seminibus.

SIR JAMES GRAHAM gives us, in another column, *another* version of his new Medical policy. This is the fourth system of treatment he has sanctioned for us in the short period of about twelve months. We admire the Minister's perseverance, and wonder at his versatility, but cannot hope that the last of his schemes will be more successful than its three predecessors. He has made gallant essays to give us the remedy we sought from him; foiled time after time, he has returned not the less hopefully or cheerfully to his forlorn hope of a legislative enterprise; but defeat, we fear, is all that awaits his well-meant and reiterated perseverance. He has proposed for himself the task of doing good things to the Profession, while he persists in the design of contenting those whose success depends on the policy of evil, and the next session will teach him the conclusive truth, that he has aimed at mastering an impossibility. *He might as well attempt to legislate for the connubial bed.* We have already anticipated the details of his proposed changes; our opinions on them are registered in our two preceding numbers. This week, therefore, we take our stand on the great probability that we are to receive no legislation from the present government, and proceed earnestly to consider what the Profession should in the meantime do for itself.

First, let us premise, and with no personal ill-feeling to the existing Colleges, that at this instant they are unpopular as regards their members, unsuccessful as regards their management, and most unserviceable in reference to science. Gladly would we see their deficiencies filled up and their worldly fortune bettered; but it is idle to disguise the fact that they want almost everything that can put them in kinship with the scientific tendencies of the day. Whatever their capabilities, they have rulers who are indisposed either to educe them or turn them to advantage. Science asks for national institutions, and legislation offers us as their substitutes a few select clubs; and the cogged dice of private influence settle that high standing in the Profession which should depend on the ennobling demonstration of superior merit. The British Profession of Medicine is emphatically without its National Institution; and its honours and high places are the chance-born conveniences of a select few rather than the achieved distinctions of the best of many.

Hopeless of the power of the Minister, despairing of any good from the good intentions of the corporations, whither should we look for efficient succour? There is no answer but one. To ourselves! In the words of Polonius—

"———To thine own self be true,
And it must follow as the night the day,
Thou canst not then be false to any man!"

Or as another poet has expressed in hacknied words the same sentiment—

'Who would be free, *themselves* must strike the blow."

By a conjunction of favourable circumstances, which we have no occasion to dilate on, the remedy is happily in our own hands, if we have the skill, courage, and good faith properly to apply it. Good government, it is true, should not, in a well-regulated state of society, depend on our deserving it; but when it does, its absence leaves us small ground for reasonable complaint. If we will not rise to the labour of evolving out of the jarring elements before us the ameliorations within our power, our sluggishness and want of public virtue deserve too well that we suffer. We merit to live unpitied under the mismanagement we rail at.

The calamity of mankind is, that the actual presentation of great opportunities finds us ordinarily insensible to their real importance, and hence we risk the imputation of tediousness or exaggeration in constantly reminding our readers that the National Association of General Practitioners cannot, in the present exigency, be pondered on too much, or turned to account too industriously. It offers us the lever power we require. The largest institution which the voluntary efforts of the Profession have as yet formed, and having the acknowledged sympathies and support of nearly four thousand men in actual medical practice, it represents, not unfairly, the whole English Medical Faculty. Formed equally of Physicians, Surgeons, and Surgeon-Apothecaries, it is the only scientific body in Britain that represents the unity of Medicine, and enforces the common brotherhood of its professors. Recognizing, too, in every act of its management the principle of responsibility to its members, it presents to us the grand idea—so favourable to the advance of science—of a learned profession using its aggregate funds and influence for its own high purposes after its own will and discretion.

The important query arises (thrown out by us before)—may not that which has grown from a small district meeting to a medico-political potentiality, rise by the same voluntary agency to a collegiate institution of the country? May not that which is to-day the representative assembly, and executive head of the Profession, become to-morrow the National Faculty it is asked to be? WHY may it not?

What is it the Profession so much needs as a National Faculty? What is there for which it would so much struggle? While giving every member additional honour, it would rob no man of the distinction he possessed. It would give us self-government and responsibility, fresh incentives to industry, new rewards to merit, a wholesome stimulus to science. It would incorporate all in one brotherhood, and disperse a thousand mischievous jealousies and rivalry. It would show the world that there was one common ground on which every disciple of Hippocrates could meet; teach society that Surgeon, Physician, and Surgeon-Apothecary, dealt alike in the same maladies and same medicaments; evoke confidence in the patient, by the truth that the principles of treating diseases among all classes of *legitimate* Practitioners were one and indivisible, and elevate the healing art before the world high and prominently above all the pretences and imitations of empiricism.

The interests of society and the Profession alike imperatively call for this National Faculty. We wish to disclaim all exaggeration in reference to the present corporations, but the fact is well known, and cannot be concealed, that they are doing infinite damage to Medicine in private society and in the eyes of the public generally. Their anomalous number—their conflicting rivalries—their suspicious, because interested, examinations—their invidious and perplexing titles, their incomprehensibly divided practice, and still more singular elevations, have made Medicine ridiculous, and flung a shade of reason over the wet sheets of hydropathy and the infinitesimal doses of homœopathy. To such a pass have things come, that put a patient under one of the "Pures" of the College of Surgeons, or an "Elect" of the College of Physicians, and you disgust him into the arms of Empiricism. The celebrities of Medicine and Surgery, as evolved by the present system, have sapped all confidence in our Profession in the circles in which they move. The distinguished "ineptitudes" that represent us have made empiricism respectable to the acute denizens of fashionable life. The Duke of Cambridge, in the very face of his Chambers' and Brodie's, makes the homœopathic Doctor Quin his Physician in Ordinary; and the Army and Navy Boards authoritatively refuse to let a Chambers' physician or a Brodie's surgeon into the service, unless they prove by *another* examination that they have been not only graced with college diplomas, but *properly educated!*

On all sides, therefore, still more from the state of public opinion than our own dissatisfaction, is the *need* of a National Faculty demonstrated.

Is the difficulty, then, of supplying the need great or insuperable? Most certainly not, if we are "true to ourselves," if we ourselves "strike the blow." The National Association has yet a further development to undergo. The moment that circumstances (and they are hastening) force it to deliberate on the propriety of becoming a "National Faculty of the Physicians and Surgeons of Great Britain and Ireland," their numbers will be doubled. Thus offering in their new change of position a remedy to many of our grievances, and a solution of most of the difficulties of Medical Reform, there would be but one mind in the Profession in promoting a triumphant result. An eminent Council Board, elected by the whole Profession, would beget the most entire confidence, and exclude the chance of serious dissension. The possession, at a nominal fee, by every legal Practitioner of a diploma from an examining board of European celebrity, would give a common bond of feeling and interest to the whole Profession, and the establishment of a worthy National School of Medicine would bring about the new Faculty, the rising generation of Practitioners. Let them have their strict examinations (public) before the first examiners of the time, and few pupils would fail to present themselves. True, studies at the school, and examinations before the Faculty for a time would be only voluntary; but what else but voluntary have been the examinations by the College of Surgeons? Let the diploma be a certain test of high merit, and it will not fail to be sought. And who shall say how long it would be before Government would recognise so useful a "Faculty?" We have not yet forgotten the charter granted to the Pharmaceutical Society, and it would be odd, indeed, if the Government, when it had actual experience that our new Institution worked well, would hesitate to make for it the concessions it proposed in May last, when no such evidence could be adduced in its favour.

THE ROYAL COLLEGE OF SURGEONS.

ON Wednesday the expected election of three new Councillors came off. The charter provides for three vacancies annually, the three *elected* Councillors having the honour of annual retirement, unless the secession or death of one or more of the self-elected Councillors (as was the case in reference to Mr. Thomas) produces vacancies without such retirement on the part of the new men. The retirement this year of Mr. Thomas left Mr. Wellbank in office, and the Councillors to be re-elected were Messrs. Cutler and Scott, with a third gentleman to supply the place left open by Mr. Thomas.

So early as two o'clock Fellows began to present themselves, and at three the theatre contained about 120 electors, some of whom were from the country. Among them we noticed Messrs. Soden and Norman of Bath, Mr. Warrington of Margate, Mr. W. J. Wickham of Winchester, Sir John Dorall, &c. &c. The London Fellows mustered very strongly, and among them were Messrs. Scott, Cutler, Aston Key, and Gossett. The President, Mr. S. Cooper, arrayed in a gorgeous new scarlet robe, now made his appearance, and taking the customary place of the lecturer, faced the audience, supported on either side by Messrs. Lawrence and Travers, the Vice-Presidents, the other Members of the Council occupying various seats dispersed about the theatre. Mr. Cooper now opened the proceedings in a very low tone, expressing his hope for good temper, wise elections, and happy terminations. The Secretary then read in a sonorous voice the bye-laws relating to the election of Fellows, repeating the advertisement convening the meeting, with the announcement of Mr. Gossett's intention to propose himself as a candidate. This being done, the Secretary transfixed Mr. Gossett's name on the summit of the balloting-box. Other boxes were similarly ornamented with the names of Messrs. Scott and Cutler. Now commenced the election. The Fellows wishing to have their share in the proceedings, advanced to the table and received one, two, or three balls from the Secretary, as they thought

proper. The disposal of the balls occupied at least an hour, and the arrangement in reference to the voting did not seem to give general satisfaction or inspire the most perfect confidence. The electors in some cases did not dispose of a ball for or against Mr. Gossett (who seemed, to the surprise of everybody, to have got suddenly under a cloud of unpopularity) and by this means the electors had the power, in the confusion of the meeting, of giving an extra ball for or against either of the other candidates. Mr. Lawrence, in a very *masterly manner*, and with dignified sleight-of-hand, discharged the responsible duty of counting the balls, the expression of many a sinister countenance saying very legibly, it might be better done by a better man. The proceedings, though perfectly honest, did not to many look so. Mr. Cooper announced the result with a smile.

Mr. Gossett was defeated by an immense majority; receiving at least 82 black balls from his fellow-members, with the negative condemnation of many an additional neutral. Out of the whole body of Fellows he could scarcely have had a dozen votes—the reason currently whispered for this terrific reverse, so little probable a few days since, being his proposal by Messrs. Eccles and Gay, together with the extraordinary imprudence of that gentleman in partially identifying himself at the last hour with the *Lancet*. Mr. Scott was elected by a moderate majority; so also was Mr. Cutler, showing that Mr. Gossett's defeat was owing to no over-estimation of the worth of his competitors. Several Fellows were now retiring, when they were informed by the President that another election was to take place. Mr. Bransby Cooper then proposed Mr. Aston Key, a nomination seconded by two or three other gentlemen, and the ballot taking place, it was announced amid the cheers of the assembly that he was elected by as large a majority as that which defeated the expectations of Mr. Gossett. The congratulations poured on Mr. Key were as universal as they were enthusiastic. The meeting then dispersed.

THE ALTERED BILL.

In the House of Commons, on Monday evening, Sir James Graham rose to express his intentions in reference to the Medical Bill.

He said, that if he acted in accordance with his own ease, he should at once have abandoned these bills; but it had nevertheless been his intention to have proceeded with them this session if the state of public business would have allowed of it. He was now, however, compelled to withdraw them; but he did so with the pledge of reintroducing them in the early part of next session. Moving the bills to be committed *pro formâ*, he would state the alterations he proposed. He persisted, first, in his design to incorporate the General Practitioners, and to fix their examination at twenty-two; he maintained his two examinations—but now changed their order. The first examination should be held, not by the Board of Physicians and Surgeons, but by the College of General Practitioners. After competency had been shown at this examination, he proposed that the candidate should go before a joint Board of Physicians and Surgeons, who should give another examination; and, if successful in both, he would not only be a Fellow of the College of General Practitioners, but a Member of the College of Surgeons. The General Practitioners sought a union with the College of Surgeons, and this plan provided for the meeting of their wants. He proposed that the fees for the examination before the joint boards should be raised; and that the new General Practitioner should pay, in addition to what his own college required, twenty guineas; to be divided thus—five guineas to the Physicians, five guineas to the Surgeons, and ten guineas to the Hunterian Museum. He had also made up his mind to concede a supplemental charter to the College of Surgeons, under which Members of a certain standing, producing testimonials to their character from a certain number of Fellows, should be admitted to fellowship. In this way, the number of Fellows would be considerably increased. He proposed also to provide for equality of education and examination in Ireland and Scotland with England, by arranging for two examinations in the latter parts of the empire. Surgeons for the army and navy, besides the examinations of their own Boards, would be examined by a joint board of Physicians and Surgeons; but for the first five years subsequently, they would not be competent for general practice, unless possessing the diploma of the College of General Practitioners. He proposed to leave the Universities of Cambridge and Oxford exempt from the operation of the bill. He proposed, also, that the Members of the Council of Health should be reduced from nineteen to thirteen as the maximum, and that they should all be appointed by the Crown.

Mr. Wakley eulogised the great services of Sir James Graham; feared that the bill would be unsatisfactory; and hoped for a concurrence of all parties to pass it.

BOOKS RECEIVED.

Elements of the Comparative Anatomy of the Vertebrate Animals; designed especially for the Use of Students. By RUDOLPH WAGNER, M.D.; edited by ALFRED TULK. 8vo. pp. 264.

The translator is well known by his contributions to natural history, and has our best wishes that his work may meet with the success it deserves, i. e. a very considerable sale. The bibliography added is really valuable, and Mr. Tulk makes something like a conditional promise of a descriptive atlas, which would certainly not be less serviceable. Of the work of Wagner itself it would be superfluous to say a word.

Observations on the Present Mode of Nominating to Appointments in Public Medical Charities. By JOHN SUTHERLAND, M. D., Senior Physician to the Liverpool Dispensaries. 8vo. pp. 11.

Dr. Sutherland has some strong, and, we think, just opinions on medical charitable appointments, and a recent practical experience of some of their inconveniences, arising from defeated candidateship, has, luckily for the public, sharpened his anger to the point of urging him into the perpetration of a book—albeit a small one—against them. Dr. S. will not allow that the appointments are useful on the score of emoluments through practice, or that they should excite gratitude on *our* side; and he insists that if serviceable in giving professional experience—as they may be—they should be vacated after short tenures, to diffuse the advantage as much as possible, and to enforce on each the policy of making the best use of his time. He then argues thus:—

"The object of the subscribers is to find the most fitting man to carry out their intentions, and common sense teaches us that this should be done in the most simple manner, without entailing unnecessary trouble on any party, and with all respect to the private feelings of the candidates, and also to the dignity of the medical profession. It is an idea that has often been expressed that none of these appointments should be entirely gratuitous; but that in order to enable the holders of them to devote sufficient time, consistently with their other duties, a salary to some amount should be given. This, however, is not the present question, further than it points to a way of filling up vacancies, which is practised in the medical charities of Liverpool, where the offices have a small salary attached. Parties applying have to send in their testimonials and appear before the medical board, which, after due inquiry, recommends to the committee the best qualified party, and the committee appoints to the office. This is found to be a very short and effectual process, and it is one in which the feelings of all parties are properly consulted. Very different, however, is the procedure when the office is purely honorary. The present plan is this. A vacancy is declared in the newspapers. Then follows advertising by all the candidates. Next, the sending ou circulars or testimonials. Then canvassing personally and by friends; and lastly comes the main difficulty of getting voters, who have promised, to the poll. The real object of electing the most competent individual is thus put entirely out of the question. It is apparently never thought of; and consequently the result of the poll is not necessarily a proof of any other thing than the activity with which the successful candidate has advertised and canvassed. A. beats B.; a very good proof that A. is a better canvasser, or has more influential friends than B.; but by no means a proof that A. is better adapted for the office than B., which was really the question to be settled by election. A good foot race, or the drawing of lots, would be both shorter and more satisfactory processes to all parties, because they would save both time and expense. When we examine the system more closely, it is really astonishing that the profession should submit to its existence for a moment. It is expected that individuals holding the position of gentlemen in a learned profession should advertise, and give their pretensions publicity to the utmost of their power. Now if there were no other act than this, it would be sufficient in itself to condemn the whole proceeding. There is nothing more repugnant to the feelings of a man of true honour than to adopt such a measure."

The additional mischief of this degrading course is, that it seduces men to become candidates when they have no hope of succeeding in any thing but in the designed aim of publishing flattering certificates, and hawking about, under a thin disguise, for practice. Dr. S. now gives his strong protest against the canvassing system in general, as unjust to the charitable subscribers, degrading to the medical candidates, and mischievous to the patients, who thus often fail to get the most skilful attendant. Dr. Sutherland proposes his remedy:—

"When a vacancy occurs let it be advertised, and let the candidates be directed to fill up and send to the institution a form of application as follows:—

"*Form of application to be filled-up by the candidate.*

"1. Name.

"2. Age.

"3. Kind of qualification.

"4. Date of admission to the profession.

"5. Length of time in practice in town.

"6. Whether holding any public appointment, and for how long.

"*Declaration to be signed by the candidate.*

"I hereby promise not to advertise, canvass, or in any other way to solicit votes, either personally or by friends, for the appointment for which I am a candidate. "Signed

"Proposed by "Seconded by

"Such a form might be kept ready prepared, and infringement of the promise might be punished by striking the candidate off the list. When filled up it would contain nearly all the information desirable, which the voters might easily extend by inquiry of their medical attendants or others. Let a verbatim copy of all the filled-up forms be printed and sent to each voter, along with the following form of proxy. One sheet would answer for both:—

"PROXY.

"Sir,—You are particularly requested to fill up the subjoined proxy, with the name of the candidate for whom you desire to vote, and send the same addressed to me at on or before the day of (Signed)

"N.B. No proxy can be received unless the subscription be previously paid.

"I hereby tender my vote for one of the candidates, &c.

(Signed)

"The proxies might be directed to be sent to the board room of the institution, or elsewhere, within a week of their being issued, and opened by the committee on the day of election. The name of the successful candidate only might then be made public, and the proceedings would end."

We must return to this subject; but, in the mean time, we should be heartily delighted to find that the empirical system of advertising and canvassing for public appointments gave way under mutual arrangements to some more gentlemanly procedure. With one-tenth the wisdom of the clergy, public

charities, instead of insidiously undermining the high character, and wearing away the profitable practice of the profession, would be a source at once of honour and emolument, without being in one tittle the less a boon to science and to the really destitute. We want among us a little more of the self-reserve and personal dignity shown by the other professions. An Oxford divine is offered a bishopric worth thirty thousand pounds a year, and shyly takes it, with the exclamation, "Nolo episcopari!" Some wretched dust-bin of a dispensary has just killed by fever its gratuitous, we beg pardon, its "*honorary*" medical officer, and forthwith we supply from our gentlemanly ranks a hundred clamorous candidates for the "distinguished honour" of being nominated successor!

Outlines of Chemistry, for the Use of Students. By W. Gregory, M. D., Professor of Chemistry in the University of Edinburgh. Part II. Organic Chemistry. London: Taylor and Walton.

We have already noticed favourably Part I., and see no reason for withholding our meed of praise to the part now before us. The whole work appears a judiciously compiled manual of chemistry. The following *resumé* on the interesting subject of Fermentation is a fair specimen of the author's general manner. Of course, Liebig is Dr. Gregory's unique authority:—

"*Action of Ferments on Organic Compounds.* Of this action the best known and most important example is the fermentation of sugar, by which it is resolved into alcohol and carbonic acid.

"The circumstances under which this metamorphosis occurs are these: the sugar must be dissolved, the solution must have a certain temperature, and there must be present a ferment, such as yeast or some analogous body. In the juice of the grape a ferment, the fibrinous or caseous constituent of the juice is naturally present; and Gay Lussac showed that the contact of atmospherical air was necessary to commence the fermentation, but that this contact with the atmosphere might be only for a very brief period, after which air was no longer necessary. It is obvious that the air acts by inducing a state of change in the ferment, for if any ferment, previously exposed to the air, be added to a pure solution of sugar, fermentation will take place without the mixture being exposed to the air after the ferment has been added.

"Berzelius and others conceive that the ferment acts by contact in some way not very clearly defined, by catalysis, as it is called, as they conceive sulphuric acid to do in the formation of ether from alcohol. But Liebig has proved that in this latter case the acid first combines with ether (oxide of ethyle) forming sulphovinic acid (bisulphate of oxide of ethyle), and that this compound at a temperature rather higher than that at which it is formed, is decomposed into hydrated sulphuric acid and ether which distils over. The same chemist has pointed out many other instances of the effect of contact, even in inorganic chemistry: such as the action of oxide of silver on peroxide of hydrogen, where the former compound, by contact with the latter, not only decomposes it, causing oxygen to be rapidly given off, but is itself decomposed, losing all its oxygen; the solution in nitric acid of an alloy of platinum and silver, while platinum alone is insoluble in that acid; or the action of carbonate of silver on certain organic acids, which cause a disengagement of carbonic acid, this disengagement being attended with a partial reduction of the oxide of silver.

"These, and many other more familiar cases, particularly those where a compound is decomposed with detonation in consequence of a slight touch, or gentle friction, a moderate elevation of temperature, or the contact of another substance (*e. g.* chloride of nitrogen with oil) all tend, according to Liebig, to establish the doctrine that in certain compounds the balance of affinities is unstable, and therefore easily overturned, either by chemical or by mechanical influences.

"The compounds which are capable of fermentation or any similar metamorphosis, are all of them bodies in which such an unstable equilibrium exists: they are all, in point of fact, easily decomposed by many different agencies, such as heat, acids, bases, oxygen, chlorine, &c. &c. Now, we can offer no other explanation of these facts of fermentation than this, that when a body in a state of progressive change, the particles of which are consequently in a state of motion, is placed in contact with another body, the particles of which are in a state of unstable equilibrium, the amount of motion mechanically communicated to the particles of the latter from those of the former, is sufficient to overturn the existing equilibrium, and by the formation of a new compound establish a new equilibrium more stable under the given circumstances.

"There is nothing unphilosophical in this explanation, and it is to be considered as the best theory of fermentation yet attempted. According to the view of Liebig, a ferment is merely a compound in a state of decomposition, capable of setting in motion, and thereby bringing also into a state of decomposition, the particles of another compound, the existence of which depends on a nice balance of affinities.

"On the other hand the view adopted by Berzelius, according to which fermentation, and all the other phenomena of chemical change produced by contact are the results of a peculiar unknown force, the catalytic force, coming into action when certain bodies are placed in contact, appears unphilosophical, as, in the first place, assuming the existence of a new force where known forces would suffice to explain the facts; and, secondly, as furnishing no real explanation, but merely acknowledging, indirectly, our inability to offer any such explanation. When we ascribe an effect to catalysis, we are only saying, in other words, that we cannot account for it; catalysis is thus merely a convenient term for all that we do not understand. And to the use of the word in this sense, namely, as a name for the agent which produces certain effects, the agent itself being unknown, there would be no objection, were it not that catalysis has been employed to account for phenomena not only different from each other, but actually of an opposite kind. For example, platinum, in causing *the combination* of oxygen and hydrogen, is said to act catalytically, and the action of oxide of manganese, or oxide of silver in decomposing peroxide of hydrogen, that is, in causing *the separation of* oxygen and hydrogen, is also called catalytic. This example proves how loosely the word has been employed, and how vague are the views which have led to its introduction.

"A variety of important and interesting processes come under the head of actions caused by ferments; the production of alcohol from sugar, of oil of bitter almonds from amygdaline, and of lactic acid from sugar of milk, are all examples of this; and in each of these cases, the ferment is peculiar. In the case of sugar it is yeast, or gluten undergoing eremacausis and putrefaction; in the case of amygdaline it is emulsine, a peculiar modification of albumen; and in the case of sugar of milk it is caseine, the nitrogenised constituent of the milk.

"The access of air is required at first to yield oxygen to the gluten, &c., which then entering into eremacausis, or if air be excluded, into putrefaction, are capable of acting as ferments.

"In the actions induced by ferments, we are to distinguish those in which some external element or elements are added to those of the compound, which cases resemble ordinary decompositions, from those in which the elements of the decomposed body merely transpose themselves, producing new compounds. The latter are properly and strictly termed metamorphoses. Fermentations, in which oxygen is absorbed, are examples of eremacausis, and it has already been mentioned that a body in a state of eremacausis acts on other bodies as an excitant of the same change, that is, as a ferment.

"Indeed, most ferments, whether they induce eremacausis, or a more pure metamorphosis in other bodies, are themselves in a state of eremacausis, at all events in the commencement of the change.

"The subject of fermentation and ferments will be hereafter more especially considered, in connexion with fermentescible compounds: here the subject is merely treated in a general way

"Putrefaction, under ordinary circumstances, partakes largely of eremacausis, and differs from the ordinary kind only in the offensive odour of some of the products, chiefly compounds of sulphur and phosphorus, as sulphuretted and phosphuretted hydrogen. When air is excluded, putrefaction goes on, provided moisture be present, and it is then a metamorphosis, giving rise, in the case of vegetable matter putrefying under water, or in the strata of mines, to gaseous products, such as marsh gas and olefiant gas, constituting with air the fire-damp, and carbonic acid, which is the choke-damp, of the miner.

"Animal matter, in a state of putrefaction, as putrid flesh, blood, cheese, or wine, acts as a ferment, and is capable of causing the metamorphosis of sugar into alcohol and carbonic acid, as well as of inducing eremacausis, and also propagating a putrefactive decomposition analogous to its own. Thus, it is well known that fresh cheese if inoculated with decaying cheese, soon passes into decay, spreading from the seat of the inoculation.

"We shall, hereafter, see that it is probable that some poisons and miasmata act as ferments on the blood. The singular sausage poison of Wurtemburg is animal matter in a peculiar state of decay, and does not contain any poisonous *compound*, only a poisonous *state* or *condition*; and the same principle may hereafter be found to furnish the true explanation of contagions.

"Fermentation, putrefaction, and eremacausis are all promoted by the same circumstances, and arrested by the same influences. Antiseptics are substances which by combining with the ferment, or a part of it, or even with the body to be fermented, prevent the continuance either of the decomposition in the ferment, or of the fermentation itself. Corrosive sublimate and arsenic, which are powerful antiseptics, combine with animal matter, and form with it stable compounds; creosote combines energetically with albumen, &c. &c.

"In fermentation, properly so called, the elements of the ferment take no chemical share in the metamorphosis of the body acted on by the mechanical agency above explained. That body is resolved into two or more new compounds of less complex radicals. The elements of water may or may not take part in the change; when they do, as in the case of sugar, the weight of the products, in this case alcohol and carbonic acid, is equal to that of the sugar, *plus* a certain weight of water. As, when the water is passed in vapour over carbon at a white heat, the carbon is shared between the oxygen and hydrogen, producing carbonic acid (or oxide), and carburetted hydrogen, so in the metamorphosis of sugar, and other analogous cases, we have on the one hand an oxidised compound, (in the case of sugar represented by carbonic acid,) and on the other a compound in which part of the carbon is united to all the hydrogen (in the case of sugar, the alcohol). Similar results are obtained when alcohol or acetic acid are metamorphosed by heat, and this may be viewed as a general character of the metamorphosis of non-nitrogenised bodies; namely, that the carbon is divided between the oxygen and hydrogen.

"In putrefaction, again, the ferment plays a chemical part in the change, and two or more compounds, the ferment and the putrefying body or bodies, combine to give rise to new compounds, with or without the elements of water. Putrefaction is generally the characteristic transformation of nitrogenised compounds, and the very great tendency of such compounds to undergo transformations is well illustrated by the spontaneous metamorphosis of a solution of cyanogen in water. Such a solution contains the four principal elements of organic bodies; and its transformations may be said to be the only case of putrefaction which has been as yet carefully studied.

"The solution after a time becomes brown and turbid, and deposits a dark matter, containing ammonia, united to a compound formed of the elements of cyanogen along with those of water. This matter being insoluble, undergoes no further change. Such a compound might arise from the reaction between 2 eq. cyanogen, and 4 eq. water: thus, $2\ C_2\ N + 4\ H\ O = NH_3 + (C_4\ HNO_4)$; according to some, the brown matter contains no ammonia, and is $C_4\ N_2\ HO = 2\ C_2\ N + HO$.

"Another change is that in which water is decomposed, each of its elements uniting with cyanogen, and producing cyanic and hydrocyanic acids; thus: $2\ HO + 2\ C\ N = (C_2\ N,\ O + HO) + H,\ C_2\ N$.

"Another metamorphosis gives rise to oxalic acid

and ammonia. In this case 1 eq. cyanogen acts on 3 eq. water; thus: $C_2 N + 3 HO = NH_3 + C_2 O_3$

"But cyanic acid cannot exist in contact with water and other acids: it is instantly metamorphosed into bicarbonate of ammonia; thus: $C_2 N O + 3 HO = NH_3 + 2 CO_2$.

"Towards the end of the process, when ammonia has become predominant, the cyanic acid produced undergoes a different metamorphosis. It now unites with water and ammonia, and may possibly for a time exist as hydrated cyanate of ammonia: but at all events that salt, if formed at all, is soon transformed into urea. $NH_3 + C_2 NO + HO = C_2 H_4 N_2 O_2$ = urea

"Again, the hydrocyanic acid gives rise to another brown solid body containing cyanogen or paracyanogen (possibly mellone also), and hydrogen; and, along with this, oxalic acid, urea, and carbonic acid, by metamorphosis already described.

"Lastly the hydrocyanic acid in contact with water, and an acid or an alkali (here oxalic acid or ammonia), undergoes another metamorphosis, and is transformed into formic acid and ammonia; thus: $H, C_2 N + 4 HO = NH_3 + C_2 HO_3, HO$.

"Thus cyanogen, a binary compound, along with water, another binary compound, gives rise to no less than eight different compounds: 1st, the black compound, containing the elements of cyanogen and those of water, possibly $C_4 H N_2 O$: 2nd, ammonia, NH_3: 3rd, cyanic acid, $HO, C_2 NO$: 4th, hydrocyanic acid, $H, C_2 N$: 5th, oxalic acid, $C_2 O_3$: 6th, carbonic acid: 7th, a brown solid, containing cyanogen (paracyanogen) and hydrogen: 8th, formic acid, $C_2 HO_3, HO$: and in addition to these, three bodies, formed by the combination of two of the above eight, and containing all the four elements; namely, 9th, oxalate of ammonia: 10th, bicarbonate of ammonia: 11th, urea.

"This striking example is well adapted to give a clear idea of the immense variety attainable, when, instead of two binary compounds, two ternary or two quaternary compounds, along with water, are concerned; and of the slight modifications of external circumstances which are required to produce results so varied, all the above substances being produced in a liquid at the usual temperature."

Photography Made Easy: a Practical Manual of Photography. London: E. Mackenzie.

The author describes himself as a practical chemist and photographist, and his work offers internal evidence that he has been guilty of no misdescription. From all we observe, this little book contains everything known that can elucidate the science or facilitate the practice of photography, and many of our readers may be induced, from a perusal of its contents, to establish themselves forthwith as amateur photographists, especially as the employment may probably subserve physiological and pathological researches in a far more efficient manner than any yet dreamed of. There is no such draughtsman as Nature in the hands of the photographist. The "Practical Chemist" inveighs with much force—and certainly not less propriety—against the attempt to make patent rights (which fetter daguerreotyping in England—and in England* alone) extend to the exercise of the art in private life for purposes of amusement or instruction. This is surely too bad. Daguerre, pensioned by the French government for throwing open his discovery, and that very discovery inhibited in England as the scientific amusement of a private family!

The Retrospect of Practical Medicine and Surgery. Edited by W. BRAITHWAITE, Surgeon to the Leeds General Eye and Ear Infirmary, &c. Vol. XI. January—June, 1845. London: Simpkin, Marshall, and Co.

The Half-Yearly Abstract of the Medical Sciences, &c. Edited by W. H. RANKING, M. D., Cantab. Physician to the Suffolk General Hospital. Vol. I. January—June, 1845. London: Churchill.

However much the year 1845 may do for medicine, it will have no ground of complaint that any portion of its labours has passed unnoticed, or escaped unrecorded. No scientific research may pine through the fear of an absent historian. What with our own "Progress of Science," to which we annually devote about a thousand columns of our close type (or in other words, the equivalent of four or five closely-printed octavo volumes), and the periscopes of the monthly and quarterly journals, and the yearly retrospections of the Provincial Medical Association, and the four annual volumes of the esteemed contemporaries we are noticing, the medical science of the present day surely cannot parade, for one of her grievances, a want of historiographers. The immense cerebral activity of the Profession seems principally tending towards journalism, and the matter for regret to new-comers is to find, that while the class of writers is as legion, that of readers is anything but unlimited.

In the suit, which of the rival abstracts is the better, it would be ungracious and invidious in us to enter. Both editors are honourably known to their brethren; if one has the distinction of longer experience to plead, the other has the set-off of fresh and unabated ardour; and both exhibit an industry of research, and a discrimination of judgment in the service of the Profession, which commend them to its warm support. Both have our cordial good wishes.

HOSPITAL REPORTS.

WESTMINSTER HOSPITAL.

Urethro-Vaginal Fistula.—The subject of this lesion, a married woman, of robust frame, aged about thirty, had contracted some venereal affection, probably gonorrhœa, from her husband about four years ago: from this cause she suffered considerably for many months; and she states that more or less internal tumefaction in the genital organs has existed ever since.

About eight months ago the urine began to escape involuntarily; this incontinence gradually increased, and at the present time the whole of the secretion escapes by the vagina, and she is unable to void any portion by a voluntary effort. On examining the vagina with a speculum, the tissues on the vaginal aspect of the urethra, particularly at its orifice, appeared to be considerably thickened and indurated, and a fissure was discovered commencing about an inch from the urethral orifice, extending in a direction rather obliquely to that of the urethra for a little more than an inch, and communicating with that canal. The patient was admitted into the hospital on Monday last, and taken up into one of the upper female wards, where she was operated on by Mr. Brooke, who is officiating at the hospital for Mr. B. Phillips, in his absence. The operation adopted by Mr. Brooke for the closure of the fissure was both novel and ingenious.

After lightly touching the edges of the fissure with potassa fusa, Mr. Brooke introduced three of his bead sutures (a description of which has lately been before the profession), by which the edges of the fissure were very accurately held in apposition. An elastic gum catheter was subsequently introduced into the urethra, and retained there by a T bandage, to prevent the urine from accumulating in the bladder, and insinuating itself between the edges of the fissure.

Mr. Brooke preferred the application of potassa fusa to paring the edges with a scalpel, on account of the extreme difficulty of removing the whole of the mucous surface by the latter means; if any portion, however small, were left, union could not of course be obtained. After the application of potassa fusa, the union must necessarily take place by granulation, and not by adhesion: it was, however, observed to be the peculiar advantage of this suture, that the parts united by it might be retained in apposition, without its cutting through or producing irritation, for a time amply sufficient for complete union by granulation. Mr. Brooke stated that in one similar case in which he had successfully applied this method, the sutures had remained for a fortnight, and in another for three weeks.

The speculum made use of in this operation is of a novel form, and extremely well adapted to the purpose for which it was contrived. It consists of a cylindrical tube closed by a rounded end: the handle which is held towards the pubis is turned up at right angles to the tube, in order to allow a catheter to be introduced through the speculum into the urethra, if required as a guide to the depth to which the needle should penetrate. An aperture is made near the closed end of the tube, large enough to allow the edges of the fissure to project into the interior, so as to be under the command of the needle. The opposite side of the cylinder towards the fourchette is cut off obliquely as much as possible, and furnished with a lip to prevent the fourchette or caruncula being nipped by the finger or the handle of the instruments.

After the beads were sufficiently approximated, the knots were placed on the free ends of the threads by a very ingenious apparatus: it consisted of a small conical roller placed obliquely at the extremity of a handle, by which a loop made at the end of the thread was run up close to the bead; the loop was then drawn tight by means of a small forked instrument, the notch in which was just wide enough to admit the thread. The operation was performed with exceeding skill and dexterity, and reflects the highest credit on the operator.

Up to the time of our going to press the case has progressed favourably, no urine having passed since the operation, otherwise than through the catheter: we will take another opportunity of communicating to our readers the result of this novel operation.

THE UNIVERSITY OF EDINBURGH AS A MEDICAL SCHOOL IN 1845.

(To the Editor of the "Medical Times")

SIR,—In our former article on the Ophiology of Schlegel, translated in part by Dr. Thomas Traill, also a Professor in the University of Edinburgh, we endeavoured to show, judging from that production with a reference made to facts and circumstances both numerous and notorious, that the whole system of Scotch colleges wherever established, whether in Scotland or England, in Edinburgh or in London, was a sheer fraud—a humbug—an insult on common sense. All this, we know, has been much better told by the *Times*—"the Thunderer," as that great-journal is called; still it may be useful to deal with details, and to go into detail. The Premier is in love with the system, seemingly because it is a Whig scheme, and proposes inflicting it on Ireland. In London by dint of a good deal of expenditure in the advertising line, the Scotch thing called "Stinkomalee" has got on amazingly, and if it has produced no original works, it has, at least, given us some well-printed re-publications of the works of others. Proceed we, then, with a brief examination of the anatomical text-book of the most famous of these "honour shops," or rather "diploma-shops"—the University of Edinburgh (the thing, at the other end of the rail, is below notice)—of the text-book of the *leading class* "of this, or of any other, medical faculty!" written by a gentleman in the prime of life, and surrounded by the labours of a train of anatomical ancestry, with the aid of numerous colleagues, selected by the town council—the patrons, *as being the best they could get* (this is the cant of the patrons) to fill their chairs; able anatomists all around him, willing to revise the sheets as they appeared. Here is the production—the result of the Scotch system of colleges! Let it not be said that this is merely the production of *one man*, and that a whole college ought not to be made responsible for the egregious errors of one person. We deny the argument. Had competent persons existed within the walls of the college, such errors would have been corrected. It is *the system*, and confident we are that in this opinion most of our readers will agree. Contrast it with Paris, Berlin, Heidelberg, Vienna, or any other sound university, and see if any professor dared to have published such a work. It is the system, we repeat—the direct result of an abuse of patronage unexampled as regards educational institutions in ancient or modern times. From this impure and filthy source have flowed innumerable evils, such as the degradation of science—the withering the young and ardent mind, and above all the destruction of all the learned societies.

Elements of the Anatomy of the Human Body. By ALEXANDER MONRO, Tertius, Professor of Medicine, &c. in the University of Edinburgh. 2 vols. 1831.

This work forms at this moment (1845) the text-book of the students of the University of Edinburgh; its author is an *examiner*, and is admitted to be the best anatomist the school possesses.

At page 11 of the second edition the professor presents us with the following *morceau* :—"Animals that breathe air are provided with ribs, and there are additional cartilages, on which the gills of fishes are placed!" Our author would here fain insinuate that animals breathing air *alone* have ribs, and that the ribs have been given them for this purpose. Finding this to be rather strong, and contrary to fact, he hints that fishes have *additional* cartilages for the display of their gills. This, however, is just as much contrary to fact as the other statement about the ribs, the additional cartilage being merely the hyoid apparatus found in all vertebrate animals. While reading the professor's description of these same hyoid bones, we almost fancied that he had never handled them. "The os hyoides (p. 296) is not immediately (excepting in a very few rare cases) connected with any of the other bones." We had thought the stylohoid ligament a very constant bond of union between the hyoid bones and the basis of the skull—not always ligamentous, it is true, but still a constant bond of union. It appears not to be so, however. "The cornua of the os hyoides are two in number, and where the body of the os hyoides joins the cornua a small styliform process, called appendix, rises upwards and backwards. I had occasion to see an instance in which a small bone, nearly an inch long, united the extremities of the styloid processes with the cornua of the os hyoides." The professor had better look again at the preparation; he will find himself in error. The bone in question will join what he calls the appendix. The doctor has been writing from memory or at random.

The description of the muscles is generally admirable, suited, no doubt, to the capacity and memory of the "university student." Take a specimen—the description of a muscle, which it would occupy some twenty minutes to dissect, and nearly as many to describe accurately:—"Costo scapularis or servatus anticus major." "This muscle is connected to the nine superior ribs, and is inserted into the whole length of the base of the scapula. The under part of this muscle pulls the shoulder downwards and forwards, and the upper antagonises the under." And this is all of the vast serratus—the great bond of connection between the extremity and the trunk—that muscle which the descriptive anatomist takes such pains to exhibit fully; that muscle to which Jules Cloquet has devoted for its illustration one of his finest plates!

The assertion, which is altogether without foundation, that the bursa beneath the psoas and iliacus, and that beneath the extensor muscles of the leg, are worn through in aged persons, and so frequently communicate with the cavities of the respective joints, is repeated in several parts of the volume, although the professor must know that the statement has been refuted over and over again to those with whom he must have been intimate; but then this was the opinion of "my father," and of course is sacred.

The doctor's mode of counting the teeth of animals is singular enough: "some animals, as the ox and sheep, have teeth only in the under jaw," (p. 478). In such a sheep's-head eating country, is it not incredible that the professor of anatomy in the "*leading*" university should never have put his fingers into a sheep's mouth, and counted the ten or twelve good sound molar teeth, of no small size, which occupy the upper jaw; the doctor means, no doubt, that these animals have no incisive teeth—but he does not say so. What follows is, if possible, "better and worse." "Others, as the mammoth and the elephant, have only two grinding teeth in each jaw; these are in constant use, but they are provided with a succession of teeth." Now, geologists tell us that no mammoth has lived since the creation of the present order of things; so, to class the elephant and the mammoth thus familiarly together, is a kind of anachronism in its way; and in respect to elephants having only two teeth in each jaw, the doctor will find *four* generally, that is, two on each side. Perhaps he means this, but he has not said so. Again, the elephant does not use his teeth constantly; they cannot be said to *be in constant use* any more than the kitchen kettle; they are not in use when the animal is asleep. How it was with the mammoth we do not know, but as the modern Athenians know every thing, especially those who have attended "classes" in the "far-famed" university, the professor may be able to tell us. What he probably means is, that, by *use*, the molar teeth of the elephant are rubbed down, and ultimately destroyed; and, to provide for this destruction by trituration, a succession of teeth is beautifully provided, whereby the succeeding tooth is constantly forcing forward to occupy the place of the one so destroyed. But still this is mere conjecture as to the doctor's meaning, for there is not one word more in the text than what we have just quoted.

The professor's notions of the functions of the gullet differ from the best authorities; we mean of the gullet of the amphibia: as thus—"I had occasion to open the gullet of a large snake, within the gullet of which I found the body of a frog half dissolved; the gullet in this class, then, possesses a solvent power upon animal substances." This is not the opinion of that prince of ophiologists, M. Schlegel, for a translation of a part of whose great work on serpents we are indebted to the very learned Dr. Thomas Stewart Traill, lately practising midwifery in the good town of Liverpool, and now professor of medical jurisprudence in "the far-famed university." "The gastric juice of serpents (p. 60) is only secreted by the portion of the stomach near the pylorus (and not by the gullet); for the animals which are taken out of the stomachs of snakes are always decomposed at the lower portions, whilst the parts near the gullet do not exhibit the slightest traces of putrefaction." No doubt this statement by Schlegel is at variance with one in the preceding section, but this may be an error of the translator, or an oversight of the worthy ophiologist.

By this time we fancy we hear the reader exclaim, "Spare us; we are satisfied with the dissection of the first volume! We see the humbug perfectly—nothing can exceed it!" But we say, no! Three new colleges are to be got up in Ireland on the same system, and two have been formed in London already, filled with persons resembling our author most studiously. The advocates of the system are bold, numerous, and insolent, swollen with a fierce corporate mediocrity; the school infects its pupils, and they stand by their class and order. Now, it would not matter if it merely infected its own pupils, but it does worse. Young men come up by hundreds to such a school, as being the honour-school; they discover immediately, or, what is more usual, know beforehand, that nothing is to be learned there; that it is merely the school, is merely the shop where honours are to be bought; to keep terms with the professors they fee them several times over, though not required to do so;[1] they quietly attend out-door teachers; they acquire from them *the whole* of their practical knowledge; and so soon as this is obtained, behold, my young spark directs his attention steadily to the "honour-shop;" becomes a "university student," sports his horse and grinder, carouses with professors, talks largely about "degrees," &c These are the men—we could name them—who, when they get to India (bad bargains, God knows, to the Company), will occasionally assemble and toast Dr. Monro and the University of Edinburgh; that is, a lecturer into whose class-room they never entered, and a school from which they received no instruction. It is, indeed, quite a common matter of talk with students to count up, not how often, but how seldom they attended so-and-so during a whole session: Dr. M. twice; Dr. A. four times; Dr. T. three times; in the mean time their good-natured friends supplying the requisite cards. The average attending number, for example, of Dr. C.'s class during the past winter was 78; of Dr. A.'s, 56; of Dr. A.'s, 37.

We now return to the second volume of the text-book of decidedly the best man in the university. It was cunningly observed to us by the son of a stickler for the existing order of corporate bodies, that it was not fair to criticise a work which was out of date. The ingenious miscreant!—this is the style in which such persons defend themselves and their rotten beastly institutions. Out of date! Is Haller out of date? Is Hunter? Is Albinus? How can a work embracing the elements of human anatomy, drawn up by a comparatively young man in the year 1831, with first-rate anatomists all around him, and the command of the first anatomical works on his table; how should such a work get out of date? Is Euclid out of date! No; but "the Elements" put the university out of date! It smashed your patronage, most pure book-vending patrons; it diminished the prices you got for your chairs; it told the world some awkward truths! Seeing that this was the production of your best man, as unquestionably he is, what was to be expected from the others? Answer—nothing. And so it was.

We shall now follow the professor through a portion, at least, of his second volume, reminding the reader that, as in the first, so here, a single page can occasionally furnish twenty specimens of error; error in thought, or language, or matter of fact, or conclusion.

The learned professor (p. 3) tells us, that in the class amphibia "there is a peculiarity of structure, viz., a communication between the ventricles of the heart, in order that these animals may remain under water for some time without a supply of air." Indeed! how admirable! how complete the theory! But why is it that those malformed children in whom this very arrangement sometimes occurs, cannot remain under water for some time without a supply of air? Explain this to us, most sapient modern Athenian! Had you not better say, that a crocodile's lungs differ *also* from those of a mammal—that his brain differs too? Why keep to the heart alone? Will the heart alone explain his amphibious nature?—or rather, in point of fact, has this formation of the heart in the reptile anything to do with his amphibious character? The professor's description of the diaphragm is admirable. "The smaller diaphragm (p. 13) takes its rise by four crura of unequal length." Good; four instead of two; but no matter. "The longest crura arise from the fore-part of the fourth lumbar vertebra, and adhere to all" (we thought only to four) "the vertebræ of the loins, by means of a strong ligament." What ligament? And you have forgot to tell us the origin of the *shorter crura*, which have escaped you entirely, as well they might, having no existence. But the masterpiece of the work is the professor's description of the pericardium; it is here as a medical professor that he shines. "The pericardium, (p. 20) or capsule of the heart, is commonly said to contain that organ, but it is, strictly speaking, on the outer side of it, as that capsule is composed of two distinct membranes, the outer of which is the pleura, (!!!) continued from the mediastinum (!!!) and the internal, the *other fibrous* (!!!) lamina is a membrane which is reflected over the origin of the great blood-vessels, to form the external covering of the heart itself."(!!!!)

There cannot possibly be a doubt that this passage stands unrivalled in the history of medical literature, and that nothing like it could be found in any work. Human ingenuity might be challenged at great odds to crowd into so few lines so many serious fundamental dangerous errors; but this is not the evil. There was not a single individual "*professor*" then, and perhaps even yet, with one exception, who could have corrected any one of the twenty errors it contains. It speaks volumes as to the state of the school; it declares in language not to be mistaken, that the school from which this emanated had ceased to be a place to which a father could send his son with the slightest chance of a sound education; that if this was the best, as it really was, what could be the worst? The reasoning would

[1] Whig reports savour commonly of the scoundrel and cheat. Some years ago, when a clamour was raised about the number of *classes*—of imperative classes which the poor student was *obliged* to fee—a thorough-hearted Whig professor got up a document, a statistic, in fact, to show that students took many more classes than they were *absolutely* required to do, and fee'd several of them twice. Yes, good sir, no doubt they do; but you took care not to mention that the student knew that he was *bribing* by *so doing* his own examinators. Is it not a most scandalous and infamous thing that *three professors of surgery* should sit on the *medical board* of a university which can issue only *medical degrees*, avowedly for the purpose of inducing the timid student to fee his examinators? We could name the men, and prove the assertion in at least a hundred instances: some of them very flagrant.

be just. The H.'s, the D.'s, and that set, were below notice, and the A.'s and C.'s, who followed them, were, in these respects, not a whit their superiors. Then did they come down with a vengeance, until one of their crack chairs did not pay £400 per annum, many much less. But, still, was the professor over-paid, seeing that the labour, which is worthless, merits no remuneration. Then fell the number of students from 865 to 329; then tumbled the Royal Medical Society from 45 to 5, until it might be said to have ceased altogether; then disappeared from the journals of the day the flash accounts of the annual dinner of the Society, and then the illustrious Kit ceased annually to get fuddled at the said dinner, and spirt out his filth upon honest men, who did not happen to belong to "*our* corporation;" then was extinguished the "Plinian," the "Cuvierian" and the numberless other little dodges got up by the hangers-on of the professorial establishment, and then, at last, did the public estimate the reputation of the diploma of "our far-famed university" against the other diploma-shops, and (horrible even to imagine) the many-headed monster gave a seeming preference to St. Andrew's!

The reader, we trust, will excuse us offering any comment upon the doctor's description of the pericardium; it were unwise to attempt it. What! the heart placed outside the pericardium! the outer layer of the pericardium merely the pleura!! and the inner layer of the pericardium a fibrous membrane reflected over the heart!!! O, ye wiseacres—patrons of institutions—by whatever name you are called—town-councilmen—crown—his lordship—the senatus—pleasant gentlemen!—how faithfully do you adhere to the old maxim: the corporation is everything, the public nothing! Let us proceed. "When blood, (p. 22) recently drawn, and mixed with water, is exposed to a microscope, it is found to be composed of a watery part, and of particles deeply coloured." Here is a discovery! If blood be mixed with water, the water will be found in it, "if exposed to a microscope;" but why not say, viewed or examined under a microscope, or through a microscope? The ancient Athenians spoke a language, and that a pure one; the modern Athenians speak a dialect, and that a vile one. Ancient Athens was remarkable for all that adorned civilized man; modern Athens—alas!

The professor cannot state the plainest fact in elementary anatomy simply as it is; as thus: "the right side (p. 28) of the heart is considerably thinner than the left; the former has hence been called by Haller the margo acutus, and the latter margo obtusus." Every anatomist knows that these names are applied merely to the edges of the ventricles, and not to the sides of the heart.

But, as if the professor was determined that no anatomist in the world should remain ignorant of what sort of person the patrons of the University, the town council, have selected to fill the chair of anatomy in their "far-famed University," the doctor repeats in this very page (28) the monstrous error formerly alluded to. "The heart," he says, "is covered by a fine and transparent portion of the pleura" (mark this, reader, the pleura) "which is *reflected* from the *pericardium*." Enough—enough! we hear you cry enough!—and so it is enough to raise a cry from all honest men throughout the kingdom, demanding, in a voice of thunder, that the public educational institution of the country should be rescued from the infamous hands, in which they are now vested. The following description of the tricuspid valve is most amusing:—"The valve (p. 36) between the anterior auricle and ventricle consists of three principal parts, and is somewhat of a triangular form, with its basis fixed to the columnæ carneæ of the ventricle: hence it is called the tricuspid valve." Turn we next to the larynx, although it is a matter of indifference where we open the volume—the text-book of the University. Bear then in mind, reader, the text-book which the student is expected to learn—the text-book of the *examinator* who holds at his mercy the fate of the examined, damning him with a word!

"The vocal cords (p. 76) rise from the fore part of the arytenoid cartilages, and extend *backwards* to the thyroid cartilage." The professor means *forwards*, of course; but, *ce n'est rien*. Between these, quoth the learned gownsman, there is a chink called the rima glottidis; now we always understood that term applied rather to the fissure between the *true vocal cords*; but still all this is of but little importance to the *physician*—the medical doctor, with whom it is still quite enough to know that the brain is in the head and the stomach in the belly. There is a most amusing account of the "coats of the windpipe," which is so completely in the university style—the style of "our far-famed university," that we cannot refrain from quoting it.

"*Of the coats of the windpipe.*—The windpipe has several coats. It has a cellular coat, and within, the chest is covered by the mediastinum posterius." We beseech both the reader, and the compositor and printer of the above passage, to look to the punctuation; it is unique. It is a specimen, moreover, of "the lectures;" and altogether illustrates very happily the condition into which an institution may rapidly fall where the son follows the father (Monro), and grandfather too; the nephew the uncle (Alison and Gregory); the son the father again (Home); the son the father again (Christison); yet, in the sequel, we shall find this was rather a better, or at least not a worse order of things, than "tools succeeding to their employers"—cringing, despicable, sycophant expectants, crawling into chairs through the merit of all unworthy arts.

Let us return to "the coats of the windpipe." There is an old saying, and we think a true one, namely, that it is disgraceful to a man not to know that which he professes to know, or rather what he ought to know. Our readers, perhaps, may imagine that we are going to be personal, and apply this to the professor of anatomy; reproaching him, in the face of all Europe, by the above passage of his utter ignorance of anatomy: by no means. The word anatomy has various meanings; with a *medical* faculty, especially a university faculty, it merely means what we said above about the position of the brain and stomach. The candidate for honours (!) is expected to know that the heart, generally speaking, lies in the thorax; that a foreign body may get into the appendix vermiformis, and by ulceration cause death; that there is an organic change of the kidneys called Bright's disease, improperly, however, since it was rediscovered about six years afterwards by Dr. Christison; with sundry other little crotchets, as familiar to the grinder as household words. Therefore it is that we do not blame the professor for not knowing anatomy, seeing that he knows as much as any ten of his faculty (with one exception, and that not over remarkable) put together; as much anatomy we mean, aye, and ten times more pathology, for the doctor is really and absolutely a good pathologist. If the reader be medical, let him look again to the passage, and deeply reflect on the magnitude of the humbug which supports such an institution; and the scoundrelism lurking under the East Indian and other convivial meetings alluded to above. If he be not, let him put a few questions to a medical friend—a surgeon by all means—concealing, however, the name of the author, for there is "much in a name"—and he will then have such a commentary as will and must surprise him.

Let us hasten to close briefly, with a very few remarks, what might occupy a volume such as a Quarterly, with a mere reprint of the all but innumerable errors contained in this "text-book"—anatomical text-book of the "far-famed university."

"The pulmonary arteries freely communicate with the bronchiæ."—P. 234. This was not known before, is still doubted, or rather not at all doubtful. The tubes are called bronchi, and not bronchiæ.

"The continuation of the external carotid artery is called angular, facial, or external maxillary."—P. 243. This is also quite original; the professor probably adopts this nomenclature from his grandfather, but, not to say too much, it is rather out of date.

"The posterior tibial artery is situated under the origin of the soleus muscle, passes to the lower part of the tibia, and then divides, about an inch below the rise of the tibialis antica, into the tibial and fibular arteries."—P. 804. Alas! before we read this passage we were disposed to give some credence to a very current report respecting the Elements, namely, that they had been composed by first-year's students, who wrote Saturday themes to please the professor; but we disbelieve this now, not even a first year's student could have written the above.

We have heard it asserted by intelligent students that, in his clinical lectures, Dr. Traill described the brain of maniacs as being so firm, hard, and dry, that, on being removed from the brain-case, such brains might be kicked up and down the room without breaking to pieces. Hear what Dr. Monro says on this point.

"I have examined with much attention the brains of three maniacs, without being able to discover any morbid appearances."—P. 293. This discrepancy as to a "matter of fact" must sorely puzzle the student, and we recommend to the dean (disposed to be a little waspish at most times) to summon a meeting at the Medico-Chirurgical, and try the question. Should the maniacs of Scotland turn out to be soft-brained, one of the antagonists will of course take shelter in "Arkney," where maniacs and silly people enough abound. The disputation might even be profitable, and assume a classic form, under the name of the "Dispute des Cerebrists;" formerly, when the venerable Hamilton lived, we had the "Dispute des Stercorists;" lately the faculty was entertained to a "Dispute des Necrosists;" the "Dispute des Urinists" (Cormack versus Henderson) was settled in a scurvy way, the parties not being game. These are nice, little, quiet pieces of impertinence, which amuse a small section or two of Modern Athens, but are below our notice, or the notice of any body or institution save one sunken like the "leading" university.

O. P. Q

PENCILLINGS OF EMINENT MEDICAL MEN.

FERGUSSON.

Come, W. Fergusson, F.R.S.E.—Sir William Fergusson, Bart.—the head of surgery *that is to be*—let us have a little "sweet counsel" together. A clever man—a high man—and a man promising to be both cleverer and higher still, thou art a pleasing subject for an hour's thought to ourselves, and it may be one not useless for the appreciation of others. Justice—the bandaged dame with the scales, whose blindness, each day worse with age than the last, seems to misfit her for the useful labours the world asks from her—will, at least, have one duty done when Fergusson, placed in our columns, takes from them a week's immortality. And just for the sport, the novelty of the thing, why sha'nt a medical censor relax into a scientific justice to a worthy brother surgeon? Why not for once, careless of the small-minded jealousy of more successful men, elevate on the cleansed pedestal of the Press the excellence already singled out by its rarity? Why shall we not do your good men the homage your cunning men do themselves, and eke out a true man's worth against all odds—and they are trying—by the equally rare patchwork of a little perspicacity? Is there to be no nausea of the soul at the debasing and tedious worship of the false gods of mediocrity? No end to the triumphs of science's hypocrites—the successes of humbug's priesthood—the degradation of simplicity's dupes? We won't say; for how bring others to our mode of thinking?—but one thing can be done, even by a literary unit. If *false* fanes must be frequented, we can keep enkindled a ceaseless worship at the *true*, with the hope that the inextinguishable contrast may hold within itself the uprising phœnix of a better state of things. If we cannot depress the ill-deserving, and such is our good temper we hardly wish it, we may exalt the worthy. Be that our task.

Of the rare instances of early maturity of intellect and proficiency of learning in some of the sciences which we find on record, few are more shining than the gentleman before us. Destined in boyhood for a profession alien to medicine, and only turning his mind to the art of surgery when he had attained his seventeenth year, he had but little more than ceased in the eye of the law to be an infant, when the public recognised in him the most accomplished and crack operator of his day. Having ourselves travelled in the same rugged route, we willingly award high praise to the *athlete* who can, within the space of *six brief years*, make himself so thorough a master of his difficult art, and thus outstripping so many, so very many, compeers, secure for his name so

enviable a celebrity!—*Non omnibus contingit adire Corinthum.*

Sir Astley Cooper used to say, "that a man to make a good surgeon must walk up to his ankles in blood;" but genius is ready-made experience. Fergusson did the work of years in months.

Fergusson came squalling into the world in the year 1808, at a place where the renowned *Johnny Cope* had either to congratulate himself on the nimbleness of his heels, or to thank the swiftness of his trusty steed for having saved him from the Pretender's sword just one hundred years ago, and which, on that account, has been rendered famous in battle-story, viz., *Preston Pans*, in the county of East Lothian. His father, Mr. James Fergusson, held an appointment in the Excise in Scotland, and William was his youngest child. In early life he was removed to the ancient borough of Lochmaben, in Dumfriesshire, where his paternal ancestors (Scotch *lairds*) had resided for several centuries. He was there, under the judicious superintendence of his uncle, Col. Wm. Fergusson,* of the Royal Marines (to whose fostering care, in the dawn of his life, he was greatly indebted), sent to the grammar school, where he made such rapid progress, and showed himself to be so shrewd a little fellow, that his friends—*suadente diabolo*—were induced to think that *Willie* would make a very clever lawyer, and accordingly they forthwith christened him the embryo lawyer of the family. It having been thus resolved upon that he should be prepared for that profession, he was transferred to the High School of Edinburgh. After having been there for several years, without disappointing any of the hopes reposed in him as to the malleable and fertile properties of his mind, he was next placed in the University of Edinburgh, and having prosecuted his studies there with great zeal for a couple of years, he was told he had completed his elementary education, and must then buckle to that by which it had been decreed he should earn his own bread. He was accordingly placed with a distant relative, a high legal functionary among the scribes of Edinburgh, and there, *sans ceremonie*, put to wield the golden pen, and read Blackstone. At that time he had no objection to the legal profession, and therefore willingly entered upon its threshold; but he soon found it would not do. He was not at home, and found he could not make those rapid strides in it, which the forward bent of his mind seemed to say it was resolved only to be satisfied with. He experienced, in short, all the symptoms of having no vocation, and was, without knowing it, a great deal too good for the contaminated atmosphere prepared for him.

It was perceived that the world's law was not to be his friend, and he was, with a very praiseworthy tolerance, allowed to cut it betimes, so that in the year 1825, at which time he was just seventeen years of age, we find diplomatic arrangements going forward, ending in our hero's pupilage to our old friend Knox. Probably no one was ever more competent than that celebrated anatomist to detect in a pupil the germs of *a son of genius* in their early stages; and to the warmth and kindness of the teacher's personal partiality, quite as much as to his lecturing ability, do we owe the early zeal and industry which characterised the young alumnus. Knox, piqued at his rival, Liston, who indulged in rude boasts that "Knox might make anatomists, but could never turn out a surgeon," had long resolved on not only turning out a surgeon, but such a one as should make Liston's very laurels as an operator insecure; and with that prescient skill which formed part of Knox's character, he at once singled out the young, graceful, and laughing Fergusson as the man he could one day play against him. For successive years, between the palace in the sheltered glen, and the castle in the air, Fergusson now made the hospitals and halls his chief resort; nay, his all but continued abiding places. He has not only been known to pass *sixteen* out of the twenty-four hours of the day in the dissecting rooms, allowing himself only very brief intervals for refreshments, but heard to say that for years together, during his working hours (as he called them), his profession was not out of his mind or forgotten by him for five consecutive minutes. He was remarkable in his youth for skill in practical mechanics; and, indeed, it was an instance of this kind which first attracted Knox's particular attention to him. One day, after having scrutinised some of his handiwork in this line, he observed to him, "I think you should make a good surgeon;" and nothing gratified him more than to find he could turn out a pupil who, as he himself used to say, he was sure would make his own way in life, and do credit to his instructor. Knox, aware of the fact, that to polish one diamond another diamond must be applied to it, Fergusson was put to work in right earnest under the eye of his preceptor. In 1826 Fergusson also became a pupil and assistant of the celebrated John Turner, who himself had been the favourite pupil of John Thomson. Turner was then the Professor of Surgery in the Royal College of Surgeons in Edinburgh, and subsequently became the first Professor of Surgery in the University. Soon after this connection was formed, it is related that Knox, in speaking to a friend about it, said "if Turner, clever as he is himself, does not mind what he is about, take my word for it Fergusson will be shoving him out of his Professorship's chair some of these days." Fergusson's business now was to be engaged for Knox about his preparations, &c., in the dissecting rooms, and for Turner in all things appertaining to a most elaborate and able course of surgical lectures which he was at that time delivering; and such satisfaction did he give to both of these gentlemen, and such progress make in his own anatomical and surgical knowledge, that in the following year he was appointed by Knox to be his prosector and demonstrator, and in 1828 had the whole management of his practical rooms left to him, which were at that time more numerously attended than any other lecturer's or surgical rooms in Edinburgh, the pupils (including winter and summer sessions) being no fewer than 400. In the same year he became a licentiate of the Royal College of Surgeons, Edinburgh, and in 1829, the stripling of 21 years of age was elected, after a rigid course of examination, a *Fellow* of that Corporation! Having throughout his career pleased Knox in all things, he entered, in 1829, into a sort of a partnership with that gentleman, and bade adieu to his connection with his friend and patron, Turner. His duties were then still to take an active charge in the anatomical rooms, and also to teach operative surgery by demonstrations and lectures—the latter for the purpose of getting his hand in to a systematic course of lectures on the principles and practice of surgery, which Knox believed, if delivered by Fergusson, would add to the then seeming stability of his school; at the same time it was a condition that our young aspirant should be permitted to devote as many hours in the course of the day to private practice as he should find to be necessary; and as the glare of his abilities was then peeping out to the public, that practice soon came to be of importance. In the dissecting rooms he was always noted for prowling amongst parts which had been neglected by the pupils, or thrown aside as of no further value; and when not engaged with the pupils, he was usually to be found occupied in examining some joint, dissecting some ligament, breaking up the base of a cranium for the purpose of tracing the nerves in that locality, or in making some preparation to be added to the collection which his arrangement with Knox then enabled him to call his own, and which he thus enriched with a variety of the most beautiful specimens.

In 1831 he was elected one of the surgeons of the Royal Public Dispensary; and at the commencement of the winter session of that same year, he made his first *debut* as a public lecturer, on a course of surgery; and so extensive were his talents for the office acknowledged to be, and so much was he personally beloved by pupils, that to this, his very first course, no less than between 50 and 60 pupils paid down their entrance fees for permission to attend his lectures. He lectured, though unassumingly, with as much collectedness as if he had been accustomed to his new chair for 20 years. He was fluent and impressive; submitted his points in the clearest possible manner; edified his pupils; and received, at the conclusion of his course, the most convincing assurances from those who had been his auditors that he had not only satisfied them, but enlightened and improved them as much as his own ardent disposition to do so could possibly have induced him to desire. He was then still occupied in the anatomical rooms, and also engaged in discharging private professional duties. His fame for ability, acceptableness of manners, and kind and obliging disposition to all who had the opportunity of becoming acquainted with him, began now to gain for him a very extensive connection amongst pupils and others; and his zeal in all matters relating to surgery, by this time assured the world that he had already become a proficient surgeon; and so true was this, that he performed, what has been described to be, *the capital operation of surgery*—he successfully *tied the subclavian artery* at the juvenile age of *twenty-three* years! This accomplishment obtained for him universal applause; as it was an operation which had *only* been *twice* successfully performed in Scotland before that occasion—once by Mr. Liston, and once by Mr. Wishart. But it was not to one operation, however difficult and complicated, or to one disease, or to one part of the human frame that he had restricted himself—he had devoted himself to all, and in a very short time afterwards was able to instruct his pupils, in the lectures he continued to deliver, from his own personal experience in operations for hernia, for excisions of the jaw, for the stone, and, in short, in all important parts, and on all important points of surgery. He effected and pointed out a variety of improvements in the apparatus and instruments necessary for the performance of lithotrity; and probably on that account it was, that many persons afflicted with stone in the bladder were induced to seek his advice. In proof of the reputation in which he was held with respect to this class of diseases, no less than *ten* cases of calculus in the bladder came under his treatment within the first 12 months after Liston left Edinburgh, nine of which he lithotomized. At one of the earliest vacancies after Liston's departure, Fergusson was elected in preference to many senior candidates to be one of the hospital staff, although at that time he was scarcely personally known to a solitary governor of the institution. This gave him an immense lift in public estimation, and his private practice greatly increased immediately afterwards. In the same year of 1839 he became a F.R.S.E., and was comparatively all at once so situated in point of practice and character as to feel that he had only then to glide along with the stream if he had chosen to have been contented with his lot and fair share of the business of an Edinburgh surgeon. But no; —Liston had found the field there not wide enough for him, and why was Fergusson to be satisfied within such *reeky* limits? Liston had gone south—was he to have a monopoly of London? What was there in a name? What was there in a Liston, or what had a Liston done that there was not in a Fergusson, or that a Fergusson had not done? What could the one assume to do that the other could not; or was there to be scope for a Scotch professor of surgery at one London Hospital, and not for another at another? Upon the Council of King's College becoming acquainted with his resolution to transmigrate, although not one member of the body knew him excepting by reputation, and only one of their Professors had a slight personal acquaintance with him, yet they were too happy to have the opportunity of securing a professor of such known and acknowledged talent, not at once and unanimously to agree that he should have the Professorship of Surgery in King's College, and the surgeoncy of the Hospital attached thereto, and accordingly, in the month of May, 1840, he was elected and seated in those chairs.

His departure from Edinburgh was not only felt to be a severe loss and a source of deep regret to the medical pupils there, with whom he was a universal favourite, but of unfeigned sorrow to a most extensive circle of private friends, to whom his abilities and amiable disposition had endeared him. When he resigned his appointment of surgeon to the Royal Infirmary, its managers conveyed to him

* Mr. Fergusson's uncle, Colonel Fergusson, now second in command at Chatham, at that time a junior officer of marines, was wrecked on the coast of Leghorn, and was, with a private, the only person that escaped. When the ship blew up, he threw himself into the sea, luckily escaped the descending crush of the fragments, and, swimming the extraordinary distance of nine miles, with his companion reached in safety the coast of Florence.

their unanimous vote of cordial thanks and gratitude for the services he had rendered, and the signally usefully manner in which he had discharged his duties there. His personal friends presented him with a very valuable piece of plate, as a testimony of their high esteem for him. On that occasion, according to the *Caledonian Mercury*, May 7, 1840, amongst other speeches, we find Professor Lizars, after adverting to Fergusson's private worth and humane disposition, saying "that they had all in common with himself to regret that the honourable distinction recently conferred on that gentleman would deprive them of our esteemed and valued friend; but that consideration was comparatively trivial when they reflected on the loss which the hospital of Edinburgh and the inhabitants at large would sustain in being deprived of the services of one so distinguished in his profession. In the course of events, Liston had been removed to a more extended sphere, and now Fergusson had been led to follow the example. As to Mr. Fergusson's merits, it was unnecessary for him to say anything before an audience to all of whom they must be so familiar, but having for several years had the happiness to be a colleague of that gentleman's, as one of the surgeons to the Royal Infirmary, he might be permitted to bear the testimony of one who had perhaps the best possible opportunity of judging. He had seen Mr. Fergusson perform all the operations of surgery, from simple blood-letting up to the most trying and critical cases of amputations, excisions, lithotomy, and lithotrity, and with every signal success. He had seen John Bell operate, and he had often assisted Liston, but he would sincerely declare, that he had seen no one, not even Liston himself, surpass Fergusson. Nor was Fergusson remarkable only for his manual dexterity, and the rapidity by which he was enabled to abridge the sufferings of the patient, for in his subsequent treatment he displayed all the skill of the scientific physician. If in the visitations of Providence, he (Professor Lizars) himself should be doomed to undergo any of those operations which surgical science had devised for the relief of humanity, he would conscientiously say that there was no one in whose hands he should more readily place himself than in those of Mr. Fergusson." Fergusson's pupils likewise presented him with an extremely elegant silver cup upon his making to them his final bow, which he did under a severe conflict of feelings—on the one hand, almost overwhelmed with grief at parting from those whose affection he knew he had won, and amongst whom he was aware he had been eminently useful; while on the other, propelled to accept of the opportunity of ascending the ladder which the fairy hand of Fate had placed ready for his step, and from the summit of which he conceived he should be able not only to look back with pleasing remembrance upon the scenes he was then with *joyful sorrow* leaving, but to hold out to the rising generation a stirring example that if they would but do as he had done, many of their own names might enrich the page of history, and they also wear the laurel.

In 1828 he visited the schools in Dublin, and in 1836 made short tours to London and Paris, in each of which places the leading establishments where the medical art was taught and practised, were, of course, the special objects of his attention. From what our readers now know of him, it must at once be inferred that he has not had very much opportunity of shining forth as an author. Study, lecturing, and practice have occupied his time so fully as to have prevented that; nevertheless, he has published a variety of talented and useful papers. Amongst others, he is the author of a paper on Lithotrity, that first appeared in the *Edinburgh Medical and Surgical Journal*, which, with Mr. Key's, were long the only papers on that subject which had proceeded from the pens of our own practical surgeons, and which were highly appreciated. Besides, he published in 1842 his "System of Practical Surgery." That work, which has gone through several editions, has met with very extensive patronage in this country; and soon after its appearance it was reprinted in America, where it was greatly approved of, and by it the author's reputation has been widely circulated across the Atlantic.

The professor's operations must be witnessed by judges to be appreciated; they cannot be described with the pen. With him there is no scowl on the brow, no *apparent* determination of hand or of mind; but on the contrary, composure, a smile, placidity of countenance, and perfect self-possession. Nothing is forgotten or overlooked or not foreseen; acquainted with his subject, he knows from the first what he has to do; there is no appearance of haste, no confusion, and yet in an incredibly short space of time all is over, and without mistake or interruption from any unforeseen event. We have had frequent opportunities of seeing him, and can safely assert, that we have never either in this or any other country beheld a more dexterous or successful operator. We were present some months ago when he *excised the head of a femur*, an operation which had only been *twice* previously performed in Great Britain, on which occasion he was surrounded by many distinguished foreigners and other practitioners, and nothing could have exceeded the ease and neatness with which the whole of that rare and formidable operation was gone through. The little patient was in the theatre just *thirteen minutes*, and the result has afforded the greatest cause of congratulation—life has been preserved by it, and a useful limb restored to the sufferer. If we were called on to express in few words the professional character of Fergusson, we should unhesitatingly say, that as a surgeon (as a *surgeon generally*, because as Professor Lizars states, his extraordinary abilities are by no means restricted to excellence in operating) he is unsurpassed. His powers of detecting the nature, character, and extent of all forms of disease are only to be equalled by the promptness with which the means of cure or relief suggest themselves to his mind. He never acts precipitately where life is in question, and one standing rule with him is, invariably to acquaint himself accurately with the characteristics of his patient's constitution, and then to make all treatment subservient to circumstances.

As a lecturer he is perspicuous and forcible. His language is simple, easily to be understood, fraught with practical facts, commands attention, and is profitable. There is no pedantry or pretension about his style or delivery. Modesty, commingled with that confidence which his thorough knowledge of his subject must be considered to inspire, makes him fluent, and gives an agreeable effect to all he says. The only improvement we should be inclined to suggest in his lecturing would be, that he should habituate himself to address his auditors in a louder tone of voice. He may not be aware of this fact—singular as it is—that lecturers in London who have received their education in Scotland, generally deliver their discourses in a tone of voice so low, as frequently to be inaudible in some parts of the room.

Personally, Professor Fergusson is a handsome fellow. He is tall and straight as a young poplar, six feet high, and for his height rather thin. Whatever phrenologists might deduce from a critical examination of his head—and did they ever yet fail to find what they wanted?—there is nothing in the size or shape of it calculated to give to a casual observer an impression that he is a man possessed of the extended acquirements of which assuredly he is master. But still, darting through every trait of complacency, and even playfulness of countenance, there is a shrewdness in his eye, and a something, a *je ne sais quoi* in the whole contour of his visage, that at once satisfies the mind that he is acute and talented, and in some way or other no ordinary man. Like many of his countrymen, he has a largely developed nose—Napoleon's indication of ability, for his "large-nosed men never failed him"—his complexion is somewhat dark, his hair black, his whiskers large and ruddy, and seeming for colour and size to be left to the chance cares of Nature, who is not as particular as she might be with them. From the front, back to the summit of the crown of his head he is all but bald, and though a profusion of hair is encouraged to play the *rôle* of Cæsar's laurels, the fact of Time's triumph, we grieve to say, is but too clearly visible. Altogether he is a "kindly chiel," full of good nature and right feeling, though far from deficient, therefore, in the prudential, foreseeing virtues of his country. Upon being introduced to him one would scarcely, if at all, take him to be "a *pare*," all but in the zenith of his surgical success. There is that youthfulness about him which, generally speaking, men of his aspect long retain, and that degree of vivacity, pleasantry, and freedom from the *sombre*, that would incline a new acquaintance to look upon him as a *spicy merchant*, who had been spending his day on 'Change, and had just alighted from his saddle after a fifteen miles' ride to dinner. There is no indication about him that he is the bantling of the dissecting room, the daily attendant in the crowded wards of a city hospital, and the *thoughtful* medical Samaritan, on whose thoughts and doings lives daily hang.

He married, congenially, in 1833, an amiable and accomplished lady, possessed of considerable fortune, subsequently much increased by the early death of her only brother, to whose landed property, in Peebleshire, she succeeded. He has by her a brood of interesting Fergussons, amid whom he so truly lives in the bosom of domestic happiness:—

"That Milton's eloquence were faint,
The beauties of his home to paint;
My rude unpolish'd strokes but taint
Their brilliancy;
Th' attempt would doubtless vex a saint,
And weel may't me."

Sir W. Hamilton on the Frontal Sinus.—It is sufficient to refer those who ascribe weight to Sir William Hamilton's statements, to the protracted correspondence between him and Dr. Spurzheim and Mr. Combe, published in our 4th volume, pp. 1-67. It will be seen, that, in February 1828, a variety of facts there mentioned, and among others those relating to the frontal sinus, having been referred by Sir William and Mr. C. to the arbitration of Dr. Scott, Professor Syme, and Professor Christison, these gentlemen, after hearing Mr. Combe's objections to the skulls brought forward by Sir William as evidence, "agreed that satisfactory facts could not be deduced from them; in the first place, because the age and sex could be determined only presumptively, and even that but in a few; and, secondly, because liberty could not be obtained to lay the sinuses open to such an extent as appeared necessary for an accurate examination."—p. 34. At a subsequent meeting, "after a desultory conversation on the best method of procuring accurate facts for deciding the points at issue between Sir W. Hamilton and Mr. Combe, the arbiters proposed that, instead of examining skulls whose history was unknown, and which could not always be cut open to the requisite extent, the parties and umpires should attend the pathological dissections at the Infirmary and Fever Hospital; by which means they hoped that, in the course of a few months, a sufficient set of correct observations might be procured, with all the necessary collateral circumstances. This proposition was agreed to; and a few days afterwards the first examination was made in presence of all the arbiters at the Fever Hospital." Here, however, the investigation was allowed to drop: and until data, derived from "*a sufficient set of correct observations, with all the necessary collateral circumstances*," be procured, Sir William's ingenious pleadings, elaborate ridicule, and captivating display of learned names, will be expended in vain. It is highly desirable that such an investigation should be made; and if any cool, candid, industrious, and accurate observer shall thus succeed in proving any statements made by phrenological writers respecting the frontal sinus to be erroneous, we shall cordially welcome the correction. Truth, not victory, is what we desire; and if, in our progress towards it, the dicta of Gall, or Spurzheim, or any other phrenologist, should be overturned, there would be no reasonable ground for either pain or astonishment in the discovery that phrenologists, like other men, had fallen into error. That in all cases much beyond puberty, the frontal sinus throws a serious difficulty in the way of phrenological observations in the superciliary region of the head, is universally allowed; the difference between the phrenologists and Sir William Hamilton respects chiefly the extent of the obstacle. And here we would caution his readers not to receive too confidingly as phrenological doctrine what he presents as such—for example, "the singular fancy" which he is pleased to ascribe to them, "that these cavities are abnormal varieties, the product of old age and disease."—*Phrenological Journal*.

PROGRESS OF ENGLISH, ITALIAN, AND AMERICAN MEDICAL SCIENCE.

THE BICARBONATE OF LIME IN DYSPEPSIA.—Dr. Basham has published a paper on the medicinal uses of the bicarbonate of lime dissolved in an excess of carbonic acid, in some cases of indigestion. The particular preparation which Dr. Basham uses is the carbonate of lime, obtained from the Carrara marble, held in solution in water by means of an excess of carbonic acid. It is prepared in a manner similar to soda-water, and is said to be both palatable and refreshing. The particular forms of indigestion in which this preparation of lime has been observed to be most serviceable are, the irritable gastric, follicular gastric dyspepsia, and a form most frequently met with in London, among particular cases, occasionally of chronic character, the symptoms unquestionably depending on a congested state of the mucous surface of the stomach, and the symptoms in the majority of cases agreeing in type with the inflammatory gastric dyspepsia, as described by the late Dr. Todd, of Brighton, but which Dr. Basham calls congestive, or chronic congestive dyspepsia, as the case may be of recent or of long standing; heartburn, occasional gastrodynia, pain at the epigastrium, furred, brownish, clammy tongue, and thirst, being the most marked symptoms common in such cases. In many of these cases, the fur on the back of the tongue has a brownish-yellow hue, and there is a disagreeable alkaline or bitter taste in the mouth; and if a piece of reddened litmus be placed on the tongue, the secretions will be found strongly alkaline. There is great thirst, particularly on first rising in the morning, and frequently an accumulation of thick tenacious mucus about the fauces and pharynx, which is hawked up with some difficulty. There is seldom any great loss of appetite, except in the more chronic cases, nor do the bowels always exhibit any very marked irregularity. The urine, however, is either high-coloured and scanty, or more copious, and depositing minute orange-red grains of lithic acid. Such symptoms often depend merely on high living, or irregularity and imprudence at table; among the poorer classes, on the intemperate use of fermented liquors. In more aggravated cases, patients will complain of a burning sensation, or even pain proceeding along the gullet to the stomach, chiefly excited on swallowing either fluids or solids, and followed by a hot and similar unpleasant situation at the præcordia, and generally lasting from a few seconds to a minute or more after ingesta have been swallowed, constituting the true gastrodynia. The symptoms now mentioned are common to some forms of complicated indigestion, but they are common also to the temporary derangement from which the stomach suffers after a succession of imprudent excesses at the table, and are unquestionably dependent on a congestion of the mucous membrane of the stomach and upper portion of the digestive organs. This state of things, if neglected, not unfrequently terminates either in chronic congestion, or inflammatory gastric dyspepsia. Carbonic acid dissolved in water acts as a sedative on the mucous membrane of the stomach; and from the large quantity condensed by the absorbing power of the lime, Dr. B. explains its beneficial effects in these conditions of the stomach. In another class of cases, where uneasy sensations are referred to the stomach during the process of digestion, accompanied by nausea, and not unfrequently rejection of a portion of the previous meal, with attacks of water-brash, the stomach being empty, there is also a characteristic state of the mental functions, hypochondriasis, and depression of spirits. In two cases lately under treatment, and occurring in patients sedentarily employed, this Carrara water, taken frequently in quantities, not exceeding a large wine-glass for a dose, very speedily and surprisingly relieved the water-brash; and when dyspeptic patients lose any of their most distressing symptoms, on which perhaps they have been anxiously solicitous, the relief obtained gives them confidence to pursue the other and more important directions of regimen and diet, on which their ultimate cure mainly depends. These cases are illustrative of what has been termed, irritable gastric dyspepsia. It must not be inferred that this bicarbonate of lime is useful as a remedy in all stomachic affections. There are some forms of the disease in which it would be, indeed has been, as injurious as in others it has been beneficial and efficient. In all cases of dyspepsia marked by atony or debility of the stomach, great oppression after eating, drowsiness, and lethargy, cold clammy extremities, hands and feet being generally moist, with a cold exhalation, an aspect of anæmia, and general indications of a want of vigour and power in the assimilative processes, such an agent as the Carrara water would be most injudiciously employed. The least distension of the stomach is, in such cases, attended by sensations of distress and oppression, and any fluids containing carbonic acid generally bring on such sensations. Again, in those dyspeptic affections in which the duodenum is the principal seat of the disorder, such a remedy would be uncalled for, if not hurtful. Another advantage derived from the use of the mineral solution, which Dr. Basham calls the Carrara water, is its employment as an adjunct to, and even as a vehicle for other remedies. In the thirst of fever, in the irritable condition of the stomach in the early stages of what is sometimes called gastric fever, taken in small quantities at a time, or even *ad libitum*, it has proved more grateful to the patient, more effective in relieving the intolerant thirst, and far easier of administration, than the common effervescing draughts. The sulphate of magnesia or soda, the tartrates of potass and soda, by being first dissolved in a small quantity of water, and this water then added, are deprived of much of their nausea and repugnant flavour. One great advantage this preparation possesses over all other artificially prepared carbonated waters, is the length of time it retains an excess of carbonic acid after the cork is withdrawn: the contents of a bottle may be taken in small quantities in intervals spread over some hours, and if the cork be merely replaced in the mouth, its effervescing briskness is retained to the last ounce. It never becomes nauseous, for if poured into a tumbler, and freely exposed to the air, it does not lose its palatableness for many hours. To those who are fond of effervescing drinks, this water will prove a most agreeable substitute for soda water. It may be drunk at table with sherry, hock, Sauterne, or with small quantities of French brandy, and forms a very agreeable and wholesome beverage; with the wines it neutralizes their free acid, and renders them more wholesome. Dr. Basham is at present engaged in experimenting with this water in cases of diabetes mellitus and the lithic acid diathesis.

UTERINE HÆMORRHAGE.—Dr. J. Hall Davis' narrates a case of uterine hæmorrhage, occurring between the sixth and seventh months of pregnancy, from placental presentation, in treating which he used the plug, and finding afterwards the hæmorrhage return, ruptured the membranes; the loss of blood continuing, the plug was again had recourse to. Ultimately a dead child was expelled by the uterine efforts, and the woman recovered. The plug used by Dr. J. H. Davis consists of pellets of sponge.

NEW INSTRUMENT FOR DEAFNESS.—Mr. Roberts suggests the insertion of a sacculus, composed of membrane, India rubber, or other suitable material, containing a small quantity of condensed air, into the external auditory foramen, so as to be in contact with the membrana tympani, by which, he says, a means of increasing the intensity of sounds would be provided, which, coming in contact with the tympanic membrane, would communicate sonorous vibrations to it, which would be transferred thence, by means of the chain of ossicles, immediately to the internal ear. The sacculus or hearing vesicle might be constructed either of membrane or India rubber; the latter, perhaps, would be superior, owing to its elasticity reacting upon the air, distending it, and hence permitting a greater amount of condensation of the air it contained, over that which membrane would allow. This sacculus might be contained in a light metallic tube, curved so as to suit the flexure of the external meatus; its external extremity might be expanded into a small trumpet-mouth, over the orifice of which the membrane or India rubber should be tightly stretched; the internal extremity should permit of the sacculus slightly projecting from it, so that it might rest on the membrana tympani. Around the tube itself some cotton wool should be evenly wrapped, and over this a portion of oiled silk, in order to make the tube fit easily and comfortably to the ear. When the sacculus is required to extend into the cavity of the tympanum, it must, of course, be made of greater length, and capable of entering that cavity, and in this case the metallic tube would require to be slightly longer; the side of the metallic tube must also be provided with an opening, to admit of air being condensed into it, and this opening afterwards firmly closed. Mr. Roberts considers that this apparatus would be applicable in all cases of deafness.

PERIODICITY OF NEUROSES.—Dr. Pidduck mentions a case of periodical neurosis, much relieved by the internal exhibition of strychnia.

INSTRUMENTAL DELIVERY.—Mr. Coventry describes a midwifery case in which he operated by evisceration, the separation of the placenta being followed by severe hæmorrhage, which was controlled by pressure, the use of the ergot, and the passage of the hand, previously placed in cold water, into the uterus. The patient recovered.

HOUSEMAID'S KNEE.—Several cases are reported from the practice of Mr. H. J. Johnson, of effusion into the bursa patellæ, and into other bursæ, in which a cure was obtained by puncturing the sac, and subsequently blistering the part.

SUDDEN BIRTH.—Mr. Blacklock places another case on record, in which birth took place with exceeding rapidity, so much so as to occur while the mother was crossing the room, the child falling on the carpet, owing to rupture of the cord. Flooding to a considerable extent followed, but was checked by appropriate measures, and the mother recovered.

GOSSIP.

ROYAL COLLEGE OF SURGEONS.—Gentlemen admitted Members on Friday, July 25, 1845:—G. Wilmshurst, G. Brooker, T. Wakley, G. S. Jones, T. Murphy, R. M. Mann, J. P. Lane, J. Johnson, W. Tickell, C. R. Prance, H. Crocker.

APOTHECARIES' HALL.—Gentlemen admitted as Licentiates on Thursday, July 17, 1845:—Henry Heginbotham, Edward Drosier Rudge.

BRISTOL ASSOCIATION OF SURGEONS.—On Thursday last, the surgeons resident in Bristol and its neighbourhood, held a meeting at the Medical Library, Orchard-street, for the purpose of "considering the best means to be pursued in obtaining those privileges to which the members of the College of Surgeons were entitled." The Chairman, J. J. Kelson, Esq., read the advertisement convening the meeting. Mr. M'Donald, the Secretary, read the Report of the Committee. The Committee had sent deputations to meet certain surgeons in Bath, Gloucester, and Taunton, to invite them to co-operate with this Association in the furtherance of its objects, the result of which had been that those gentlemen upon whom the deputation waited, perfectly coincided with the views entertained by the Association, and promised to assist it in obtaining signatures to such memorials, petitions, and protests as it might adopt hereafter. The report was adopted. Dr. Rogers then proposed "a memorial to Sir J. Graham, praying that he would advise her Majesty to grant a supplemental charter to remedy the evils complained of." He spoke in strong terms of the invidious manner in which the College of Surgeons had bestowed the Fellowship upon men who were but juniors in the profession, to the great injustice of their seniors, passing over men who were many years above them in standing. He referred also to the fact of their having entirely passed over one hospital in this city—the Bristol General Hospital, not one of the surgeons of which had been appointed Fellows, not to say anything of St. Peter's Hospital, to which he was himself a surgeon, but which he did not like to refer to, as it was generally considered only a Poor-house.—Mr. J. G. Lansdown seconded the motion, which was carried. Mr. Geo. Allen, of Pill, proposed that the memorial be adopted.—Mr. Alfred Smith seconded it, after which it was carried unanimously. Mr. J. B. Prowse then proposed that the Committee be directed to carry the same into effect. Mr. Goodenough seconded it, and it was carried.

LECTURES ON DISEASES OF THE HEART.

By D. J. CORRIGAN, M.D., Physician to the Whitworth, Hardwick, and Richmond Hospital, Lecturer in the Dublin School of Medicine, &c.

Gentlemen,—We come this evening to consider a peculiar functional disorder of the heart accompanying chlorosis, and which has been called from thence "chlorotic palpitation." A patient who has been for some time affected with chlorosis, presents herself to you labouring under the following symptoms. Anæmia, characterised by the bloodless, tallowy appearance of the surface of the body; cough, oppressed breathing, dyspnœa, emaciation, loss of muscular strength, anasarcous feet, and effusion perhaps into the cellular tissue of the body. To these symptoms, alarming enough in themselves, are added palpitation of the heart, and bruit de soufflet. Here we have a train of symptoms alarming enough to induce us to suppose our patient labouring under organic disease of the heart. We find these palpitations increased on taking exercise, and sometimes accompanied by pain in the region of the heart. Have we any characteristic mark by which we can distinguish whether the above train of symptoms denotes organic disease of the heart or not? Yes. Although the other signs might readily deceive us as to its existence, yet by carefully examining the bruit, we can from it discover a means of arriving at the wished-for conclusion. The bruit, from the peculiarity of its sound, in these cases has been by the French writers termed *bruit de diable*. The sound closely resembles that produced by the schoolboy-toy (with which I am sure you are all familiar), made of a piece of iron, or stiff leather, nicked at the edge, and strung on a cord by a hole through its centre. This, on being twirled through the air pretty briskly, produces a peculiar sound. The bruit here differs from that in organic disease in the following particular:—In organic affection the beats of the pulse being 50, 60, 70, 80, or 90 in a minute, the number of times bruit is heard, will tally exactly with this, except in cases of permanent patency of the aorta, when the sound of the returning portion of blood causes double bruit. In chlorotic palpitation, no matter what the number of pulsations may be, the bruit does not correspond with them. You cannot count the number of times in which you hear bruit de soufflet in this affection. There it goes on continuously, whirring away for one-half, one, two, three, or ten seconds; there is no intermission in it as in organic disease; *it may hold on thus for half a minute or a minute, but during this time there is no cessation.* In this distinction we possess a never-failing criterion between functional disorder and organic disease of the heart. In the chlorotic bruit de soufflet you can hear this sound also in the internal jugular vein, when the stethoscope is applied to the neck, this sound proceeding here from exactly similar physical causes as those which I have detailed in the lecture explanatory of the causes which operate in producing bruit de soufflet. In the disease before us we have the physical cause acting in full force, which is absolutely essential in producing this sound—namely, an incomplete distension of the large vessels with blood, owing to the deficient supply of it in the system. But you must bear in mind, that in a person of perfectly sound heart, and enjoying excellent health, you may have bruit de soufflet present, from some cause or other, of only momentary duration.

The treatment of this chlorotic palpitation may be divided under two heads:—1. To remove the constipated state of the bowels which always exists here, by means of purgative medicines, which are supposed to exert some specific stimulus on the uterus; of this class I think aloes the most preferable. 2. To improve the general state of health by the administration of a full diet of animal food, a moderate allowance of fermented liquors, by taking a sufficiency of exercise—walking, if possible, is to be preferred—and by the use of medicines, which are supposed to possess the property of promoting materially the formation of red blood, chalybeates, for instance. By the use of these, and all other means which may suggest themselves to you, as being useful in raising the debilitated system to a proper degree of vigour and to the highest possible tone, you will in the majority of instances quickly and effectually restore your patients to health.

There is another variety of functional disorder of the heart, consisting solely of palpitation, without any other irregularity of this organ, which we find attacking females about, or at the period of puberty, say from fourteen to sixteen, and in some instances continuing until the persons so attacked have attained the age of thirty or thirty-five. The state of the catamenia here has no influence in producing this complaint, for we meet it in persons where this secretion is regular, irregular, wholly defective, or, on the contrary, morbidly profuse, and we often meet it coexisting with leucorrhœa. It may attack males as well as females, but the latter principally, particularly such of them as have given themselves the custom of wearing tightly-laced stays, and it is often met with in persons who have naturally narrow chests. In these cases the heart may be felt beating violently, and over a large extent of surface, sometimes accompanied by pain. In no case, no matter how violent the palpitation may be, is there any abnormal sound heard. The palpitation is much increased whenever the patient takes much pedestrian exercise, though (and the fact which I am about to mention is curious) if the person has been accustomed to horse exercise she can take any amount of it without feeling any inconvenience from palpitation. We often find persons who, having been delicate in early life, and subject to this affection, on being surrounded by a numerous family in after life, tell us that they have outgrown their disorder, have become stronger than it, and that they are no longer troubled with it. A curious circumstance connected with the pulse occurs in this affection. *If the pulse (as most often happens in it) be irregular and intermittent during the prevalence of the disorder, it still continues so after the complaint has disappeared, and will continue too, irregular and intermittent, during the patient's lifetime.* If unacquainted with this fact, we might be led to infer, from the irregularity and intermission of the pulse in persons otherwise healthy-looking, the speedy accession, or even the presence of some severe disease of the heart. We frequently find this state of the pulse in delicate young females labouring under the affection of the heart in question, joined with pain of the left side, frequently extending towards the right. The existence of this pain makes them uneasy, fearing from its situation some fatal disease of the heart, and I have not unfrequently seen *the whole train of symptoms* treated by medical men as incipient pericarditis. Such an opinion is groundless, and one likely to lead to some aggravation of the functional disorder already existing. We often find this affection dependant upon spinal irritation, and the part of the column which is generally affected is the first or second, or sometimes the last of the dorsal vertebræ.

This cause of the disease is frequently overlooked both by patient and physician in their anxiety about the palpitation, until evident symptoms of spinal disease show themselves either in the usual form of curvature where the body is bent forward, or in the more severe and unmanageable form, called by the French "syphosis," when the curve is lateral and angular.

In cases where this affection depends on spinal irritation, we must immediately have recourse to the means best calculated to subdue this. For this purpose, the first step should be topical bleeding, from whatever situation the spinal irritation may occupy. This we can determine by pressure along the spinous processes of the vertebræ. After this topical bleeding by leeches or cupping, we must direct the use of counter-irritation over the seat of disease. I do not know a better remedy for this purpose than the tartar emetic ointment rubbed in every morning and night until it produces pustulation. Along with these radical means of cure we shall derive very great advantage in controlling the distressing palpitations by the use of prussic acid or laurel water in half drachm doses three times a day. Observing to follow up this line of treatment, we shall have the gratification of finding the heart symptoms disappear, according as the primary exciting cause is removed. In the cases which do not depend upon spinal irritation, we shall find our best account in a tonic plan of treatment, supporting the strength by every means in our power, and by keeping the digestive organs in proper order.

You will take care to keep in mind the difference between these last two disorders. The former arises generally in persons at an early period of sexual life, and is attended by a suppression of the catamenia; the latter arising, too generally speaking, at an early period of sexual life, but completely independent of any connection with the state of the catamenial secretion, which may or may not be healthy or morbidly profuse; the one attended with peculiar bruit de soufflet, the other unattended by any abnormal sound of the heart, but both coinciding in the material fact of neither proving a source of organic disease to the person affected.

COURSE OF LECTURES ON THE THEORY AND PRACTICE OF MEDICINE.

Delivered by C. J. B. WILLIAMS, M.D., F.R.S., Professor of the Practice of Medicine, and of Clinical Medicine, at University College.

Scarlatina Anginosa is complicated with inflammation of the throat, which is far from being of a superficial nature, the tonsils being more or less affected with swelling. The symptoms are more permanent than in the other forms, and the fever is more severe and accompanied by slight delirium, headache, and prostration of strength. The stiffness and soreness of the throat begin about the second day. There is fever and thirst at first in many instances, and in some the throat is first affected; there is difficulty of deglutition, and the fauces are red and more swollen than in scarlatina simplex; they are covered with patches of lymph. This extends to the pharynx, not commonly to the larynx, and there may be some hoarseness, and invariably slight cough. As the throat becomes worse, the skin is hot and dry, and the heat rises up to 106° to 108°, or even 112°—higher than in any other disease. The tongue is more furred, yet the red papillæ are easily seen. The rash is later in its appearance than in the simple form, and is not so florid, but deeper in colour, often less intense and more changeable; it comes and goes, and appears more in patches, but it lasts longer, and the parts where it shows most are the elbows, the chest, and the throat. In slight cases there is an exfoliation of the cuticle, like that of scarlatina simplex. In the more severe cases other local inflammations take place beside this of the throat; the ears and nose are apt to be affected by a bad kind of inflammation, leading to suppuration; the lymphatic glands, the angles of the jaws, and other parts, show it too. The internal organs become the seat of inflammation, just as they do in continued fevers. These complications are generally subacute, but as the fever is more inflammatory, so likewise the accompanying affections are more of the sthenic kind, and bear depletion better.

On the decline of scarlatina various diseases are apt to occur—e. g., effusions into the joints, rheumatic affections, anasarcous affections, with œdema of the cellular tissue, and effusions into serous sacs; and these effusions are accompanied by low degrees of inflammation. The affections occurring in these cases I have noticed are connected with albuminuria.

Scarlatina maligna is more a disease accompanied by typhoid fever, and it is also called *angina maligna*, from the circumstance of the throat being commonly affected, and the skin sometimes not at all. In most instances the fever is like that of *scarlatina anginosa*, and the rash may appear in the same way; but it is even redder and duskier in its appearance, evanescent, often shifting; the face is frequently suffused of a dark red, and congested, as I mentioned to occur in the congestive form of typhus fever; the eyes are heavy and red, and sometimes there is efflorescence in different parts, with petechiæ, but this disappears on the pressure of the finger. This is characteristic of effused blood. In this variety, too, the throat is commonly affected, and the affection of the throat is of a more diffused character. There is not only inflammation and swelling of the throat and fauces, with, sometimes, slight ulceration of the tonsils, but the cellular texture of the neck and the submaxillary glands are much swollen, and diffused erysipelatous inflammation occurs in them. The disease is by this means sometimes greatly complicated, from the difficulty of breathing and deglutition, and also from the obstruction to the return of blood from the head. The tongue in this form is usually furred, sometimes denuded, or even ulcerated; subsequently it becomes dry and brown, and the other appearances of the mouth exhibited in typhus fever are commonly present. There is soreness of the gums and teeth, and the lips are parched and dry. In scarlatina anginosa, stomatitis, or inflammation of the lining membrane of the mouth is a common thing, just as in other inflammations of the throat. The typhoid type of the malignant scarlatina is shown by the low character of the affections of the throat, which sometimes terminate in gangrene or sloughing, and also of the visceral complications and affections of the brain, that occur as in the congestive form of typhoid fever, producing coma, stupor, and sometimes low delirium, congestion in the lungs, causing dyspnœa and the various ronchi, and sometimes tending to asphyxia; also by the petechiæ and the bad appearances about the hands and feet; the rapid prostration of strength, subsultus, &c.

This disease may prove fatal on the third or fourth day, in some cases going on for eight or ten days. Recovery takes place from very bad states of scarlet fever, but the recoveries are very lingering, and much retarded by the various sequelæ, such as low inflammations occurring in parts, frequently tending to suppuration and serous effusions.

This disease sometimes appears in a mild form, quite in the character of the *simplex*, or the *anginosa*, and may turn into the malignant form in its progress; and sometimes we can trace very distinctly the causes of its malignancy, which quite correspond with those I mentioned as causing malignancy in other continued fevers, such as contamination of the atmosphere, an epidemic poison, &c.

Another variety of scarlatina to be described is the *scarlatina faucium*, in which there is no eruption, but merely a sore throat. During the prevalence of scarlatina as an epidemic many persons are affected with a sore throat, but without any rash, though perhaps there is more redness than usual of the tongue.

Now, scarlatina may be said to be at once the slightest and the most serious of eruptive fevers; sometimes so slight as not to confine the patient to bed or to require any treatment at all, and in other instances being a most intractable and fatal disease.

Morbid anatomy does not throw much light on this disease, any more than on any other febrile affections. In the early stage in the worst form no constant lesion is found, but the blood is in a fluid state, and usually the lower parts of the viscera are much disordered by hypostatic congestion and a disposition to early putrefaction, and, in the worst forms, to gangrene of the throat. There may be variously complicated inflammations of the throat. When the parts are cut open there is some swelling of the fauces and neighbouring parts, but they rarely exhibit anything more than purulent lymph with serum effused into the cellular tissue.

The sequelæ I have adverted to are local inflammations, particularly in the ear, the eye, the glands, the larynx, the bronchi, and the joints. It is said, too, that dropsy is apt to occur in the membranes; hydrocephalus has been known to ensue. The form of dropsy that succeeds scarlatina is more of the inflammatory type, and the notion prevailed that this inflammatory dropsy arose from the inflammatory action of the cellular tissue, which had its origin in the disordered action of the skin; that the cutaneous inflammations extend to the cellular texture; disturbance taking place in the one texture affects the other. Dr. Watson, of Middlesex Hospital, entertains the opinion that the skin is so much damaged in its structure by the eruption, that effusion takes place in the cellular texture from want of the power of cutaneous excretion. This I think a mistaken view of the sequelæ. You find in some cases that the urine is altered, and in some of the worst cases I have found it to be suppressed. But in the common cases the secreting power of the kidneys is impaired, and in consequence the serum passes through the kidney, and the urine is coagulable; the urea and other matters being left in the blood, become the cause of dropsy in the manner I have explained. There is no doubt that the failure of the excreting function of the kidneys is the true source of these sequelæ.

The prognosis of these affections is to be founded much on the same principles as the prognosis of continued fevers. The *simplex* variety is a trifling affection, and requires very little treatment; it is attended by no danger, but the sequelæ may be serious, and therefore require attention. In the case of *scarlatina anginosa* the danger arises from the complications, and sometimes from the tendency of the affection to become typhoid at a later period. The cases are generally of a bad description when the rash is slow in coming out, more dusky in colour, and when it comes and goes, and especially when petechiæ occur, when the pulse is very weak and frequent, and when the breath is fetid. The worst danger of scarlatina is that arising from the typhoid fever, and this form is chiefly to be apprehended in the inflammatory complications. The disease is of a more serious character in adults than in children, and peculiarly so in puerperal or pregnant women. This is a very curious fact, which one might speculate upon if there were time. It is worse in autumn than in winter or spring. Its seriousness may be evinced by this fact, that in some epidemics of the worst form that prevailed, many healthy persons were affected and died.

The treatment of the slight form of the disease is very simple; the heat may be reduced by cold or tepid sponging, and antimonial salines, the bowels being kept open. The treatment is the same as the simple *synocha*. *Scarlatina anginosa* includes the same treatment also, with the remedies for tonsillitis or nephritis. When the aphthous form occurs, diluted muriatic acid, nitric acid, or lemon-juice, are found useful in modifying the character of the inflammation. The nitrate of silver is a still better application. The inflammatory complications are to be treated according to their kind.

Scarlatina maligna is a disease on which treatment seems to produce very little impression; however, the salines and stimulants combined appear to be the most useful; acetate or muriate of ammonia, nitrate of potash or of ammonia, chlorate of potash, nitro-muriatic acid, and the decoction of bark, or a little quinine, has been known, in some instances, to support the strength somewhat against the poisonous influence of the disease. It is quite necessary to support the strength by other stimulants—wine, brandy, ether, ammonia, and so forth.

After scarlatina it is of great consequence to keep the bowels free. The kidneys appear to be defective in their power of action, and therefore they should be aided and relieved, by acting on the bowels, on the one hand, and on the skin, on the other. The rheumatic indications are colchicum or iodide of potassium, to increase the action of the kidneys. Some persons think that scarlatina may be prevented by small doses of belladonna. This notion originated among homœopathists, but it may be useful, independently of that doctrine, in doses of from three to four grains, twice or three times a-day.

The next disease is measles, or rubeola, or, as it used to be called in Italy, *morbilli*. This is, also, a contagious disease, and it may be said to be a necessary disease, as it happens once to almost every one; this is the general rule, but I have known instances where it has occurred twice. Such cases are exceptions, and are more rare than in any other eruptive disease. It very rarely occurs in new-born infants, but there is a case recorded of a child born with it. The disease spreads by contagion, and is epidemic. Small-pox and measles are different degrees of the same disease, and it is curious how it occurs in the same subject. The measles will occur first, and small-pox will come on, and be suspended, in the course of the measles. Between the time of the incubation and the latent period there are about ten or fourteen days. The first symptoms are commonly fever, headache, sense of constriction in the forehead and eyes, heaviness, and nausea, and, in children, sometimes convulsive affections. About the second or third day of the fever the eyes become swollen, the nostrils blocked up, and there is coryza, and, in fact, a cold in the head seems to be coming on, accompanied by an unusual amount of fever; sometimes, too, a little sore throat, the pulse very quick and strong, and the skin very hot, the fever being quite of the inflammatory description. About the fourth day the heat comes on the forehead and the chin; the next day in the neck, and it does not reach the arms and legs until the fifth or sixth day. The eruption appears first in the form of small red spots like flea-bites. They occur in patches, leaving interstices of a somewhat irregular and semi-circular shape. The eruption is more to be compared to the colour of the raspberry. It is sometimes accompanied by some swelling, particularly about the face and limbs, and frequently miliary vesicles appear. The fever reaches its height about the fifth day; cough and constriction of the chest may occur. After the eruption passes off there is a partial exfoliation of the cuticle, often with excoriation.

There are two varieties, one called rubeola maligna, in which the eruption is of a more dusk-

colour, and leaves the skin somewhat stained, though it is not accompanied by any serious complication; and the other variety is the *rubeola sine catarrha*, which is merely an eruption without any catarrhal affection, and what is curious in this modification is that it appears to be a more partial affection, and does not protect the system against its recurrence. The febrile symptoms appear to be the most essential part of measles, and the eruption may occur without them. The more formidable cases are those complicated with inflammation; the type of the fever is altogether inflammatory, and the danger chiefly arises from the inflammations that occur. In more rare cases the danger arises from the typhoid form of the fever.

The complications are extensive—bronchitis, pneumonia, and gastro-enteritis, and in many rare cases other parts are affected—the membranes of the brain and the larynx. There are three periods at which the inflammatory complications may occur before the rash comes out: in the first case, they are slow to appear; secondly, they may occur after the rash has come out, on the fourth or fifth day. If the rash has come out, and the complications come on, the rash fails or recedes. The third period at which they may occur is the natural decline of the rash, about the fifth day, when the rash and fever decline; then inflammation may occur. These inflammations constitute the chief danger of measles, and they must be watched, and their symptoms attended to. Whenever retrocession of the eruption appears we must examine all the organs, to find whether there are any signs of inflammation, and be careful to try to draw out the heat, and to restore the depression. As I said, in a few cases the disease becomes typhoid; this is during the prevalence of the epidemic.

Now, as to the diagnosis of *rubeola*. There is a difference between this and scarlatina; that in rubeola the latent period, from the exposure to the infection and the first symptoms of fever, is as much as from ten to sixteen days; in scarlatina it is only three to six days. In rubeola the early symptoms, besides fever, are coryza—a remarkable affection of the eyes, running at the nose, and more affection of the ears; in scarlatina, on the other hand, the throat is most affected. In rubeola the eruption occurs in two or three days at least, and more in spots; in scarlatina the eruption appears in two days, and is more diffused—in smaller spots at first, and leaves deeper interstices, which are irregular in shape, not irregular and concentric, but quite irregular. Measles may be communicated by inoculation; it has been done, but there does not seem much certainty in it. Dr. F. Hope, of Edinburgh, succeeded in inoculating a child by taking matter from the most vivid patches of the eruption.

The treatment of the simple form of measles should be mild—febrifuge treatment, the patient kept in bed, cool, but not cold; antimonial salines, in a few doses; antimony at night, and followed in the morning by salines. If the heat of surface is marked, and causes suffering, it may be relieved by tepid sponging of the hands and arms. The chief object is to watch for any complications, and treat them in the usual way, and the earlier the better. If they are neglected they are less easily treated, and are more apt to become subacute and intractable. In slighter cases, after other measures have been tried in vain, irritants are often useful: turpentine liniments to the chest, when the chest suffers, and the rash does not come out. If the eruption recedes without any inflammation it may be useful to stimulate, but chiefly to stimulate the skin; a warm salt bath should be prescribed, with acetate of ammonia and antimonials internally. In the typhoid form, ammonia, camphor, and quinine, are to be administered, as in the other cases of typhoid disease.

TINCTURE OF COLCHICUM IN OBSTINATE CONSTIPATION.—Dr. Chapman, of Pennsylvania, recommends as a medicine which rarely fails to restore the lost susceptibility of the bowels, tincture of colchicum-root given in doses of ten drops, repeated several times in the twenty-four hours. It must be persevered in for some time, and it is essential to its success that the dose be small, the object in view being attained by gradual insinuation rather than by forcible impression.

ON THE FIRST AND LAST APPEARANCE OF THE MENSES, AND THE RELATION EXISTING BETWEEN THE TWO PERIODS.

By WILLIAM A. GUY, M.B., Cantab. Physician to King's College Hospital, &c.

(For the Medical Times.)

The facts about to be stated in this communication were not originally collected with a view of ascertaining the earliest and latest appearance of the menstrual discharge, and the relation existing between the two periods; but as a means of illustrating a question bearing upon the value of the numerical method, and the necessity and importance of large numbers of observations. As, however, the number of facts which I have brought together illustrative of the first appearance of the menses already exceeds the largest collection of observations hitherto made in this country, and the facts in illustration of the latest period, and of the relation existing between the two periods, are also numerous, I am induced to publish the results, in the hope that they may form an acceptable contribution to our knowledge of this subject.

It may be necessary to premise that great care has been used in collecting the individual facts, and especially where they presented anything unusual. The ages stated are the birthdays to which the first or last appearance of the menses was nearest; thus, fifteen years will include all cases in which the menses appeared during the last six months of the fourteenth, and the first six months of the fifteenth year, and so of the other ages.

The following table shows the age of the first occurrence of the menstrual discharge in 1500 cases, and the per centage proportion occurring at each age.

TABLE I.

Age.	No. of Cases.	Per Cent.
8	1	·06
9	4	·26
10	5	·33
11	53	3·53
12	90	6·00
13	183	12·20
14	266	17·73
15	291	19·40
16	234	15·60
17	181	12·06
18	105	7·00
19	45	3·00
20	28	1·87
21	8	·53
22	3	·20
23	2	·13
25	1	·06
Total	1500	

It appears from this table that fifteen is the age at which the greatest number of females first menstruate; that the fourteenth year comes next in order, then the sixteenth, and that the thirteenth and seventeenth, the twelfth and eighteenth, and the eleventh and nineteenth, present numbers approximating closely to each other. Before the eleventh year, and after the nineteenth, the numbers are very small. In the following tables the ages are thrown together in groups of three, so as to present the results in a more compact form.

TABLE II.

Age.	No. of Cases.	Per Cent.
8, 9, and 10	10	·66
11, 12, and 13	326	21·73
14, 15, and 16	791	52·73
17, 18, and 19	331	22·06
20 and upwards	42	2·80

In more than half the cases, then, the menses made their first appearance at fourteen, fifteen, or sixteen years of age, the numbers at eleven, twelve, and thirteen, and seventeen, eighteen, and nineteen being very nearly equal, while at twenty and upwards more than four times as many cases occur as before eleven.

In ascertaining the last appearance of the menses the same care has been taken as in determining their first occurrence, and all cases have been excluded in which the cessation might be attributed to the existence of severe disease, such as pulmonary consumption.

The following table presents the ages of cessation in 400 cases.

TABLE III.

Age.	No. of Cases.	Age.	No. of Cases.
27	1	42	24
28	1	43	23
29	0	44	24

38	5	53	8
39	7	54	2
40	33	55	1
41	24	56	2
		57	1

In the following table the facts are given for periods of five years.

TABLE IV.

Age.	No. of Cases.	Per Cent.
35 and under	9	2·25
35 to 40	51	12·75
40 to 45	140	35·00
45 to 50	159	39·75
50 and upwards	41	10·25
Total	400	

From forty to fifty, then, is the period at which the large majority of females cease to menstruate, but the number during the last half of the ten years is somewhat greater than during the first half.

The relation existing between the first appearance of the menses and their cessation is a point of some interest, which, as far as I am aware, has not yet been very carefully examined. The following table exhibits this relation in 250 cases.

TABLE V.

No. of Observations.	First Menstruation. Age.	Last Menstruation. Age.	Interval.
1	8	42	34
2	9	46	37
2	10	47	37
10	11	47·10	36·10
29	12	45·34	33·34
31	13	46·16	33·16
39	14	45·33	31·33
30	15	46·30	31·30
41	16	46·14	30·14
26	17	45·18	28·88
19	18	46·84	28·84
11	19	46·18	27·18
5	20	40·80	20·80
3	21	41·66	20·66
1	23	41·00	18·00

The average period of the last appearance of the menses varies, according to this table, betwen forty-one and forty-seven years, but the interval during which the function continues varies inversely, as the age at which it begins being longer where the function is established early, and shorter where it makes its appearance later in life. This case will appear more distinctly if the observations are thrown together in groups of three years, as in the following table.

TABLE VI.

No. of Observations.	First Menstruation. Age.	Last Menstruation. Age.	Interval.
5	8, 9, and 10	45·60	36·60
70	11, 12, and 13	45·65	33·65
110	14, 15, and 16	45·85	30·85
56	17, 18, and 19	46·35	28·35
9	20 and upwards	41·45	20·45

It has been already stated that the foregoing observations were originally made with a view of throwing light upon the function of menstruation; hence it happens that I have not entered so much into detail as I might otherwise have done. I have, however, made a few short notes, which I give without comment.

In several instances the menstrual discharge, after making its appearance once only at the periods indicated by the tables, did not recur until after a considerable interval. The following are examples:—In two instances it made its first appearance at nine, and did not recur till thirteen and fourteen respec-

tively; in one case at ten, and not again till fifteen; in five at eleven, and a second time at thirteen (two cases); at sixteen and at eighteen (two cases); in three cases, for the first time, at twelve, and for the second at twelve and a-half and thirteen (two cases); and lastly, in one instance, at fifteen, and not again till seventeen.

A female not having been unwell up to her twenty-sixth year, since her twenty-fourth year, has had leucorrhœa, increasing in quantity at the menstrual periods.

The case in which the menses are stated to have first appeared at eight years continued to be perfectly regular from that period. She was first unwell before the completion of her eighth year, and her mother before the completion of her ninth year. Circumstances were mentioned substantiating the statement of the mother as to time. The girl was not larger than other well-grown children of the same age, nor were the breasts developed.

One female, who first menstruated at eleven years, had not changed life at fifty-three.

A woman, who had menstruated for the first time at fourteen years of age, changed life at forty-two, but up to the present time (she is now forty-nine) she states that she is unwell once a-year, on new year's day. There is no appreciable difference between these annual discharges and her former monthly ones.

Two females stated that they were always perfectly regular during suckling, and one female that she is regular both during pregnancy and lactation. In these cases, also, there was no perceptible difference in the discharge. A mother of seven children married at fifteen, not having previously menstruated. She had a child nine months after marriage.

A female, who had not been regular till she was married at nineteen, was unwell a few days after her marriage for the first time. She had a child at the expiration of nine months and a-half from the date of her marriage.

A female, ætat. thirty-six, menstruated at twelve, was married at nineteen, and had fifteen children in fourteen years and seven months. They were all born alive, and with the exception of one, who died at eleven months, they are all living. She did not suckle her children. Her husband is of the same age as herself. Six of the children are male, and nine females. They were all single births. Her mother had twenty-two children, and her grandmother four. The mother had twins three times, and triplets once. Of the latter one lived to eighteen years of age. She is now seventy-two years old, and in good health.

I shall conclude this communication by a short summary of the results of the tables expressed in words.

1. The age at which the greatest number of females begin to menstruate is fifteen; the fourteenth year comes next in order, then the sixteenth, while the numbers at thirteen and seventeen, twelve and eighteen, and eleven and nineteen, approximate very closely to each other. Before the eleventh, and after the nineteenth year, the numbers are very small. In more than half the cases the menses make their first appearance at fourteen, fifteen, or sixteen years of age; the numbers at eleven, twelve, and thirteen, and seventeen, eighteen, and nineteen, being very nearly equal, while at twenty and upward more than four times as many cases occur as before eleven years. The earliest period in the tables is eight years, and the latest twenty-five.

2. Menstruation may cease at any period from twenty-seven to fifty-seven years. In the majority of females that event happens in the interval from forty to fifty years of age, but the number during the last half of the ten years is greater than during the first half.

3. The period during which the menstrual discharge continues varies with the time of its first appearance, and, as a general rule, the earlier it commences the longer it lasts.

These conclusions are not put forth as original, but simply as the expression of the results of facts collected by myself without reference to the labours of others, and, as has been already more than once observed, without any intention originally of throwing any light upon the subject of menstruation.

PROGRESS OF FRENCH SCIENCE.

(FROM OUR OWN CORRESPONDENT.)

Paris, July 30, 1845.

Effusion into the Pleura, followed by rupture of the Lungs and Pneumo-thorax; Death.—Dr. Bouvier, as stated in my last, presented the left lung of an individual, aged thirty-five, who died in his wards at Lafitte. This patient was attacked three months and a half since with pleuritis, and three weeks after its commencement the effusion was so considerable that paracentesis thoracis seemed indispensable; before having recourse to it, however, at the recommendation of Professor Piorry, tartar emetic in doses of gr. vj and gr. viij per diem was prescribed. The improvement under the use of this remedy was so great, that tapping was adjourned, and after two months the state of the patient was very satisfactory, though there was still a quantity of liquid in the pleura. He was now suddenly seized with dyspnœa, sense of constriction in the precordial region, pain at the base of the chest, and fever. These symptoms increased in spite of the most active treatment, and the day before his death the matity of the left side was replaced by an excessive sonorousness without the respiratory murmur, indicating evidently that pneumo-thorax had succeeded to hydro-thorax, owing in all probability to a perforation of the lungs. The man died on the 8th of July. *Autopsy.*—Pleura containing a great deal of air, and from a quart to three pints of a yellow serosity; soft and recently formed pseudo-membranes existed, principally on the diaphragm, where several red spots were observed, proving the presence of inflammation. Left lung pushed backwards on the vertebral column; sound; crepitates in all parts near its apex, small superficial erosion, forming a small opening, through which the air entered the pleura, this was made evident by inflating the lung under water, when several bubbles rose to the surface; near this opening was a small reddish concretion, like a clot of blood; this rupture probably took place during the efforts made by the patient in vomiting. Right lung full of grayish miliary tubercles, the presence of which had not even been suspected during the patient's life.

Diphtheritis Vulvæ.—Julia Arblat, aged three months, had enjoyed good health from her birth to the 27th of December, 1844, when she was attacked with irritation of the external parts of generation, with slight discharge, followed by white spots on the labia majora.

Jan. 2.—Child pale, puny; external labia tumefied and of a livid red colour; ulcerations of a gangrenous aspect of the anterior commissure; light violet spots indicating the commencement of sphacelus on part of the left labium; very fetid sanious discharge; part of the mucous membrane of the labia majora evidently sphacelated; below the meatus urinarius a white membrane is seen; all the ulcerated parts are covered by a coating of a grayish black colour; no fever; slight gastric disturbance.

Caut. cum acid. hydrochlor. pur. mane nocteque.

3.—Parts of a brighter red; a portion of the grayish false membrane has separated, and a red surface, covered with white concrete pellicles, is observable; the clitoris and commissure of the nymphæ seem to have been destroyed; general health improved.

Repet. caut.

4.—Tumefaction of the labia majora somewhat less; their inner surface, and especially that of the left side, covered by a thick white coating; aspect of the deeper seated portion of the mucous membrane healthy. Fomentations.

R. Hydrargyr. chlorid. ℈j, pulv. sacch. alb. ℈v, ft. pulvis ter. in die applicand.

5.—Right labium better, a very small portion of false membrane remaining; on the left, on the contrary, the pseudo-membrane is still very thick, and the sphacelus seems to have increased.

Caut. lab. sinis. dextr. ut antea.

6.—State of the labia as before; on the internal surface of the left side is a deep ulceration covered by a false membrane; on the right side and at the commissures some pseudo-membranes still exist; the bluish tint observed at the upper part of the left labium is of a deeper hue; remainder of the mucous membrane in a satisfactory condition; fever; appetite good; moderate diarrhœa.

Contin. pulv. sacch. alb. et calomel.

7.—Considerable œdema of the mons veneris and labia majora; the parts at the upper part of the left external labium are evidently sphacelated for about nine lines in diameter, and the internal labium seems to be converted into a sort of shell, in which a black mass was perceived; right labium appeared to be on the point of undergoing the same process, and contained in its excavation a blackish core: fever; diarrhœa.

Caut. cum hydrargyr. nitr. acid.

8.—Sphacelus and tumefaction have considerably increased on the left side; edge of the right external lip begins to assume a gray tint; all the surrounding tissues are excessively hard, hot, and of a light rose colour; general state, with the exception of the fever, pretty satisfactory.

Caut. ut supra; statim.

9.—Tumefaction and erysipelatous redness much less; on the left side the eschar has separated, superiorly and laterally, on the right the sphacelus has extended and is not yet limited; general state good.

Caut. ad dextr.

10.—Eschar has separated on the left side; sphacelus has extended on the right, but begins to be limited outwardly; intense fever.

11.—The sloughs being completely limited, the greater part was removed; tumefaction of the surrounding parts somewhat less; still a good deal of fever; face very pale; no vomiting, diarrhœa, thoracic or nervous disturbances.

R. Calc. chlorid. ℈j, aquæ puræ ℥ x, Lotio sæpe utend. cura cum. balsam. arcæi.[1]

12.—Sphacelus limited superiorly to the mons veneris, but seem to increase in depth; excoriations of the inside of the thighs and the buttocks; slough not yet perfectly separated from the surrounding parts; edges of the wound red and slightly indurated; cough; respiration accompanied by a mucous râle, especially on the left side.

Contin. medicam.

13.—Sphacelus has increased in extent, and invaded the sound portion of the labia majora, a portion of the mons veneris, and even a part of the thighs; the child is still paler, though the general health, considering the circumstances, is not bad.

R. Pulv. cinchon. cordifol. ʒ ijss, Acid. gallic. ℈j, Camphor. ʒ j. M. ft. pulvis part dolent. applicand. Contin. balsam. arcæi.

14.—Sphacelus extended still more, and occupies all the mons veneris and the inner part of the thighs; intense diarrhœa; no vomiting; extreme pallor; fever; coma. Lotio cum cal. chlorid. Pulvis et balsamum ut antea.

15.—No change in the mortified parts; surface of the body cold; pulse and respiration extremely rapid; breath not so warm as in the normal state; death towards midnight.

Autopsy.—Skin and cellular tissue forming the labia majora et minora, the clitoris, and a part of the vagina, are deeply sphacelated; the mons veneris is in a similar condition, with considerable œdema around it.

On Rubeola, by Dr. Bouchat.—The author in this memoir describes an epidemic of rubeola which raged in 1843, at the Necker Hospital, in one of the wards of Professor Trousseau, and the peculiarity of its having been limited to this ward rendered it possible to study its various phases, mode of development, &c.—a circumstance impossible in large cities.

History.—A child, eighteen months old, was brought to the hospital on the seventh day of an attack of rubeola, complicated with intense lobular pneumonia, and was placed in a ward containing nine children, of whom one only had previously had the disease. These infants were affected as follows:—five on the twelfth day, with very slight premonitory symptoms; two from the twenty-fifth to the twenty-sixth day, with the characteristic premonitory symptoms for four days previously; of the remaining two, one had had rubeola, and the other was taken away during the fever produced by vaccination, and had a secondary eruption like varioloïdes; seventeen other children were admitted during the progress of

[1] *Balsamum Arcæi.*—R. Resin. elemi., Terebenthin, āā ℥ iv, Adip. ovill. ℥iij, Ad[illegible] ℥ij.

the disease, and two only were attacked, one on the twenty-first, the other on the twenty-ninth day.

Symptoms.—This disease is divided into four periods: 1. *Incubation* varies from twelve to twenty-nine days—a fact which can be explained only by a peculiar idiosyncrasy; 2. *Invasion*, in five cases, was very slight, lasting only twelve hours, characterised in some by redness of the eyes and sneezing towards evening, the day before the appearance of the eruption; in others it was more appreciable, and presented—smart fever, dry skin, swollen eye-lids, red eyes, lachrymation, sneezing, serous discharge from the nostrils, white tongue, buccal mucous membrane uniformly red, dry cough; in two patients there were efforts to vomit and diarrhœa (symptoms indicated by Sydenham during dentition). These symptoms lasted four days, but Dr. Guersent observed a case in which they remained a fortnight. 3. *Eruption* commenced on the forehead and face, like small flea-bites, which united so as to form large spots of various shapes, slightly prominent at first, but soon becoming flattened; colour, at first, bright rose, then pale, except during fits of coughing, when they assume their primitive colour; cough; fever; increased difficulty of breathing; lachrymation; somnolence; anorexia; mouth red, dry; tongue covered with a white fur, and presenting numerous red spots corresponding to the papillæ; abdomen supple, not painful; diarrhœa in four cases; eyes still swollen; coryza changed into a thick mucous discharge, which soon dried, so as to form scabs; harsh cough, augmented and accompanied, in six cases, with intense dyspnœa, sibilant, mucous râle, which twice was converted into the subcrepitant; cough, in two cases, came on in fits, as in pertussis. This period lasted from six to eight days, when the eruption disappeared, leaving no traces whatever, but followed by maculæ, produced by a circumscribed local inflammation of the dermis (causing an alteration of the pigmentum), which disappeared only after fifteen or twenty days. 4. *Desquammation* of the cuticle, in many cases, was imperceptible, and furfuraceous in four cases. The symptoms disappeared with the eruption, except the cough, which, in some cases, remained for a considerable time.

Mode of Development.—The only notable difference between the present and ordinary rubeola was the absence of the furfuraceous desquammation; as to the anomalies presented, they are common to all epidemics, and Professor Piorry, in his report of this class of disease, was perfectly right in noticing these immunities.

Duration of the epidemic, seventy-seven days; of each case of rubeola, from four to eleven days.

Complications.—Diarrhœa, twice; in one, it might be considered as critical; in the second, as symptomatic of entero-colitis. Secondary eruptions of eczema impetiginosa on the face, accompanied in one case by boils on different parts of the body, and in another by inflammation of the cervical glands, which terminated in suppuration; here, however, eczema of the scalp had existed before the measles, and in all probability, owing to the irritation of the skin, caused by the eruptive disease, had extended itself to the face, and subsequently gave rise to the glandular inflammation. Harsh (*ferine*) cough was in a direct ratio with the bronchitis; pneumonia, characterised by matity; bronchial respiration; resonance when the child screamed, and, in one case, by a double mucous and a sub-crepitant rhonchus on one side; pertussis, but this was probably produced by accidental nervous phenomena grafted on bronchitis.

Diagnosis was easily established from the symptoms just enumerated.

Prognosis, not serious.

Causes, evidently produced by a contagious principle, propagated by the little patient received into the Hospital on the 29th June, the development being modified according to the idiosyncrasy of the individuals, whether normal, or produced by the disease under which they were suffering.

Treatment.—When the disease was not intense, and went through its various stages regularly, the patient was kept in bed, with moderate covering, for if too hot the skin becomes the seat of a painful congestion; emollient drinks were prescribed, and abstinence from food, except milk, was enjoined. During the period of invasion, if the cough was very troublesome, Syrup. papaverac. ℥iss—℥v per diem, was given in a draught, or in the tisane. If the eruption took place with difficulty or disappeared suddenly, urtication, sinapisms, frictions, blisters, &c., were had recourse to. If the cough became troublesome when the disease was declining, emollient and demulcent tisanes were prescribed. As to laxatives, they were never administered; it was found of the highest importance not to allow the patients to go out too soon. This treatment was necessarily modified according to the complications; thus, in pneumonia, ipecacuanha was given in doses of grs. vi to grs. viij in ℥j of syrup, repeated if requisite. The immediate result of this was a diminution of the fluid accumulated in the bronchi, and afterwards the decrease of the pulmonary congestion. After the emetics, temporary blisters, frictions with the oleum tiglii, and other cutaneous revulsives were used; blood-letting may be had recourse to when the patient is strong, and the fever intense. Antimon. hydro-sulphur. rubr. gr. j, may likewise be given. In diarrhœa, starch enemata were exhibited. In pertussis, pulv. ipecacuanha and pulv. ipecac. comp., in small doses. In an inflammation of the lids, an ointment containing red precipitate, and in otorrhœa, injections with *baume tranquille* were found beneficial. Finally, as a preventive, inoculation has been recommended, but further experiments are requisite ere its efficacy can be admitted.—(*Journal de Medecine.*)

Foreign Body in the Bladder.—A man, ætat. 40, consulted Dr. Piffard in August, 1843; he stated that on the 25th April, experiencing some difficulty in making water, he introduced, per urethram, a young stalk of arundo donax, formed of several leaves rolled up. On withdrawing it, he perceived that the inner ones alone came out. His endeavours to extract the outer one having failed, he desisted, in hope that it would escape with the urine. Two days passed thus in the midst of the most violent pain, with frequent desire to make water. Urine flowed drop by drop, sometimes in a small stream. A gum elastic sound showed that there was no stricture in the urethra, and that it did not contain the foreign body. Several baths were prescribed, and on the 1st September Jacobson's instrument was introduced into the bladder when distended with urine, but without being able to seize the leaf. The next day Mayor's sound, No. 2, was introduced, and the bladder filled with tepid water; this done, the sound was removed, and replaced immediately by Jacobson's instrument. Several attempts to seize the body proved fruitless; at length, by closing the instrument rapidly, instead of a metallic sound, a dull one was heard. The instrument when closed reached zero, so that it was feared nothing had been grasped; it was, however, withdrawn, and was followed by the leaf, which had been seized at its small extremity. A day or two after the man returned home, and is now quite well. The length of the leaf is six and a quarter inches, its diameter when rolled up two lines; here and there a slight urinary deposit of a dull white was perceived. The leaf is entire, showing that none was left in the bladder.—(*Gazette des Hôpitaux.*)

On Hare-Lip.—At a late Sitting of the Academy of Medicine (vide *Medical Times*, vol. xii, p. 221) Professor P. Dubois communicated several interesting observations tending to prove the utility of, and the little danger attendant on, this operation, when performed immediately after birth, and the following case, recorded by Dr. Malgaigne, comes to the support of this opinion.

Case.—On the 5th of March, 1845, Dr. Malgaigne was called to see a male child born that morning, who presented a vertical division of the upper lip, extending from its edge to the right nostril; the lips of the division were about nine lines apart; the division extended backwards, affecting the os maxillare and the velum palati, and was so considerable that the whole of the right side of the bone seemed to be wanting; the rounded edges of the division of the soft parts were somewhat more distant from each other than the osseous portion, and the left was situated on a plane anterior to that of the right; nose flattened, ill-shaped; lip drawn to the left; right ala forcibly drawn to the right, and three times the size of its fellow, and quite flat; deglutition easy, but, from time to time, the liquids pass through the left nostril; it was impossible to place the edges of the wound in contact with each other, on account of their adhesion to the bones. The operation being absolutely necessary, in order to enable the child to take the breast, it was performed as follows:—1. With a stroke of the scissors, beginning towards the centre of the right flap, the edge was cut off as low as the mucous membrane of the lip, leaving a sort of flap. 2. The same process was performed on the left side. 3. The edges were then removed from below upwards, as high as the nostrils. 4. The lip was separated from the bone on both sides. 5. Two pins were introduced, and the twisted suture applied, the lower first; the upper presented some difficulty, on account of the right edge being unsupported by bone. 6. Finally, a part of the flaps was removed, and then united by three sutures. The child cried very little during the operation; was soon pacified; drank with perfect ease, and ejected nothing through the nostrils. Gentle pressure was ordered to be made on the cheeks, in case the child should cry much. The immediate result was—nose nearly regular; tip almost in a straight line with the root; nostrils of equal size; lip regularly formed; labial tubercle had nearly disappeared, but was replaced by the newly-formed one.

March 6.—Going on well; child has cried very little.

7.—Right nostril obstructed with some blood and mucus, which was easily removed by means of a probe.

8.—A part of the thread was removed in order to examine the subjacent parts; no suppuration nor ulceration around the pins.

9.—Upper pin and the three sutures on the flap removed; a little serous blood escaped through the holes made by the pins; no pus; the thread of the lower pin was removed, but, as a slight erosion existed on the cicatrix, was replaced by another, but without drawing it very tight.

10.—Last pin removed; a small quantity of reddish lymph escaped, no pus; the union is complete; there is, however, a small scab on the cicatrix, which was ordered not to be removed; child seemed to gain flesh; the upper lip seemed to be somewhat larger than immediately after the operation.

11.—All was going on well; but, two days after, a large, whitish aphthous spot appeared on the inferior surface of the turbinated bone in contact with the tongue; cicatrix was thinner superiorly, and inferiorly seemed on the eve of bursting; on its inner surface were one or two small whitish spots; it seemed to be continually on the stretch, owing to the efforts made by the infant to suck. The aphthous spot on the turbinated bone was touched with the nitrate of silver; gentle pressure on the cheek, if perchance the child should cry.

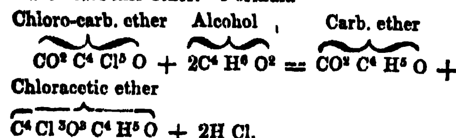
14.—Considerable improvement; cauterised surface nearly clean; application of the nitrate to the remaining portion; cicatrix presents a better aspect; scab removed, so as to examine the wound, which has healed completely, except perhaps a little towards its nasal extremity; a pin was inserted, and the twisted suture applied somewhat tighter than usual.

15.—Baby caused the pin to fall out about 9 A.M.; cicatrix firmer, closer; general health better; stools which had been out of order were more natural. Slight cauterisation of the mouth.

18.—All going on well; child takes the breast for the first time, and sucks readily; the milk does not escape through the nostrils; cicatrix is unchanged.

19.—Child puny; greenish stools; aphthæ in the mouth; takes the breast, but does not suck; to be fed with the spoon. Cauterisations. During the day an attack of suffocation occurred, which fortunately soon subsided.

20.—Better; stools natural; aphthæ improved.



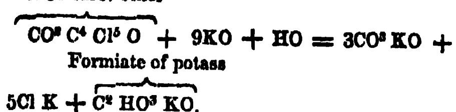
21.—Continues improving; appetite and stools normal; skin firm; cicatrix still firmer, and begins to assume the colour of the surrounding parts. This state continued, and the child enjoyed good health until the 4th of April, when, all at once, he was seized with symptoms of cerebral congestion, and died in a few hours; the cicatrix having been solid the whole time.

Remarks.—According to Dr. Malgaigne, two reasons alone counter-indicated the operation:—1. The non-development or sickly state of the child

not that it would hasten the approach of a fatal event, but because it is useless operating on a child not likely to live. 2. Internal hemorrhage, produced by the instinct which makes the child swallow the blood. As to the dragging on the two flaps, the division of the flesh by the pins, the non-reunion or the destruction of the recently formed cicatrix, they may occur at all ages, if the necessary precautions are not taken. In the present instance, the first of these accidents was prevented by detaching the lips from the bone, for it is hardly possible that such a division could, as some surgeons suppose, give rise to any serious hemorrhage. Another precaution was taken, and which ought never to be omitted in similar cases, viz., to make the pins go through the whole, and not two-thirds or three-quarters of the lip; as, on account of the division of the os maxillare, they form a species of septum, against which the tongue strikes when carried forward, instead of the inner surface of the cicatrix. The suture of the two little flaps prevents the disunion of the parts during suction, and ought, therefore, always to be had recourse to, even in simple cases of hare-lip. The pins may be left, in complicated cases, with advantage, longer than in the case just related, and only a part of the thread put in at first must be removed; and if a fresh thread is put on, it ought always to be wetted, when put on the part, with a solution of gum arabic or white of egg. Finally, as to the possibility of swallowing, many eminent surgeons consider it as impossible, but, however plausible in theory their reasons may be, still they cannot be admitted ere experience proves their correctness.—(*Journal de Chirurgie.*)

Academy of Sciences; Sitting of the 14th July.—(Concluded.)

On the action of different Substances on Chloro-Carbonic Ether, by M. Malagati.—Alcohol changes chloro-carbonic ether into an oil formed of chloracetic ether, normal carbonic ether, and unchanged chloro-carbonic ether. Formula—



Chloro-carb. ether, Alcohol, Carb. ether

$$CO^2\,C^4\,Cl^5\,O + 2C^4\,H^6\,O^2 = CO^2\,C^4\,H^5\,O +$$

Chloracetic ether

$$C^4\,Cl^3O^3\,C^4\,H^5\,O + 2H\,Cl.$$

Potass.—A weak or concentrated solution of potass decomposes and changes it into formic acid, carbonic acid, and chloride of potassium. Formula—

Chloro-carb. ether

$$CO^2\,C^4\,Cl^5\,O + 9KO + HO = 3CO^2\,KO +$$

Formiate of potass

$$5Cl\,K + C^2\,HO^3\,KO.$$

On the decomposition of Water by different Metals, when Acids and Salts are added in solution; by M. E. Millon.—The experiments performed by the author were—1. A certain quantity of zinc was divided into six parts, and placed, in six different bottles, in a solution of diluted sulphuric acid, one part acid to twelve parts water. To one nothing was added, to another a solution of bichloruret of platina (bichloruret one part, water ten parts), and to the rest saturated solutions of tartar emetic, arsenious acid, sulphates of copper and silver. The result was—

Bottle.	Zinc before Exp.	Loss.
1. Diluted sulphuric acid . .	10·119	0·028
2. Ditto, with 4 drops of the solution of bichloruret of platina	10·466	4·298
3. Ditto, with 10 drops of the solution of tartar emetic . . .	10·600	0·800
4. Ditto, with 10 drops of the solution of sulphate of copper .	9·808	1·234
5. Ditto, with 15 drops of the solution of arsenious acid . . .	10·857	3·706
6. Ditto, with 15 drops of the solution of sulphate of silver . .	10·349	0·071

Length of time, 10 minutes.

The action of the bichloruret of platina rose immediately to its maximum, and then decreased; that of arsenious acid was established slowly, but soon was equal to the former.

2. In two comparative experiments, which lasted an hour instead of ten minutes, the result was:—with diluted sulphuric acid, zinc before commencement, 10·091 grains; loss, 1·187; with addition of fifteen drops of a solution of sulphate of silver, zinc before 10·278 grains; loss, 5·527. The acceleration produced by this solution may be expressed for ten minutes by 2·4, and for an hour by 4·6. A few drops of the solution of the bichloride of mercury preserves the zinc by the formation of an amalgam on its surface. In adding ten times the quantity of bichloruret of platina, the action was twice as powerful.

3. Three quantities of zinc were added to diluted sulphuric acid, and three with the addition of four drops of a solution of bichloruret of platina; the length of time varying, the result was, with dilute sulphuric acid—

	Grains.	Grains.	Time.
Zinc before exp. .	15·104 .	Loss 0·025 .	5 min.
„ „ .	15·041 .	„ 0·058	10 min.
„ „ .	15·215 .	„ 0·120	15 min.
With addition of the bichloruret—			
Zinc before exp. .	15·352 .	Loss 3·653	5 min.
„ „ .	15·326 .	„ 6·325	10 min.
„ „ .	15·237 .	„ 7·206	15 min.

The action diminishes with the concentration of the acids.

4. With hydrochloric acid, diluted with forty volumes of water, the bichloruret of platina does not act so powerfully as with sulphuric acid, and tartar emetic produces an equal acceleration.

5. Diluted oxalic acid is without action, unless bichloruret of platina be added, when the whole of the metal is converted into an oxalate.

6. Acetic acid, with an equal quantity of water, has but a very feeble action, but it is rendered very active by the addition of a few drops of the solution of the bichloruret. The other acids, with which experiments were performed, are—butyric, citric, tartaric, and racemic. A similar effect is produced when a few drops of a solution of bichloruret of platina are added to a solution of chlorides of potassium and sodium, sulphates of soda, potass, magnesia, alkaline leys of potass, soda, and ammonia, salt water, river water, and even distilled water. Sulphuric acid, diluted to a twelfth, dissolves iron pretty rapidly; the action is increased by the addition of the bichloruret of platina; arsenious acid, on the contrary, puts a stop to all action; tartar emetic and bichloride of mercury render it less active. Sulphates of copper and silver accelerate the decomposition, the latter very slightly. Other acids were likewise examined; among them, diluted nitric acid, when poured on the iron, disengaged abundant vapours of nitrous acid gas, and a persalt of iron was produced; but if a drop of the solution of the bichloruret of platina be added, hydrogen alone is given off, and a protonitrate of iron and nitrate of ammonia are obtained. Tin: it is with hydrochloric acid that this metal presents the most striking phenomena; the result is protochloruret of tin; the effect is accelerated by the addition of the metallic solutions just mentioned. The results obtained with lead, copper, antimony, bismuth, silver, and mercury were likewise considered.

On several new Compounds of Naphthaline; by M. A. Laurent.—The substances examined in this memoir are:—*Sulphonaphthalic Acid;* formula, $C^{40}\,H^{16} + 2SO^3$. *Thionaphthic Acid*, denominated by M. Berzelius *Hyposulphonaphthic Acid* (formula, $C^{40}\,H^{16} + 4SO^3$), is obtained by the action of sulphuric acid on naphthaline. According to M. Gerhardt's law of capacities, it is bibasic, and the composition of the thionaphthate of lead is a proof, the formula being $C^{40}\,H^{12}\,Pl^2 + 4SO^3 + 4Aq.$ The water is driven off at a heat of 392° F. *Nitrogenated Sulphonaphthalic Acid*, obtained by treating nitrogenated naphthaline with sulphuric acid. Formula, $C^{43}\,H^{14} + 2SO^3$. *Chloruretted Sulphonaphthalic Acid.* Formula, $C^{40}\,H^{14}\,Cl^2 + 2SO^3$. *Bichloruretted Sulphonaphthalic Acid* $C^{40}\,H^{12}\,Cl^4 + 2SO^3$. *Trichloruretted Sulphonaphthalic Acid.*—Obtained by treating chloronaphthine with sulphuric acid, when an abundant crystalline precipitate is obtained on neutralising the solution by caustic potass. Formula: $C^{40}\,H^8\,Cl^6\,K + 2SO^3$. This acid is soluble in water and alcohol, and when the solution is evaporated, a crystalline mass like pap is obtained, which decomposes the alkaline salts, setting even the most powerful acid free. *Quadrichloruretted Sulphonaphthalic Acid.*—Prepared like the former; salt of potass less soluble. $C^{40}\,H^6\,Cl^8\,K + 2SO^3$. *Bromuretted Sulphonaphthalic Acid.*—Obtained by treating bromonaphthaline with sulphuric acid, and neutralising the solution with potass; the salt of potassium is almost insoluble. Formula:—$C^{40}\,H^{12}\,Br^2\,K + 2SO^3$. *Bibromuretted Sulphonaphthalic Acid.*—Prepared like the foregoing, with bromonaphthaline. Formula: $C^{40}\,H^{10}\,Br^4\,K + 2SO^3$. *Chloruret of Naphthaline.*—Obtained by cooling to 32° F. the oil which accompanies the crystallised chloride of naphthaline; very soluble in alcohol and ether; crystallised in light spangles. Formula: $C^{40}\,H^{16}\,Cl^8$. *Bromochloruret of Naphthaline.*—Obtained by adding bromine to the preceding. Formula: $C^{40}\,H^{16} + \frac{Cl^6}{Br^2}$ — Chloronaphthine Æ. In addition to the numerous isomeric compounds, the author obtained another by treating the oily chloruret of chloronaphthine by sulphuric acid; hydrochloric acid is disengaged. Formula: $(C^{40}\,H^{14}\,Cl^2 + Cl^8) + S^2\,H^8\,O^8 = C^{40}\,H^{10}\,Cl^6 + H^4\,Cl^4 + S^2\,O^6 + H^4\,O^2$. *Nitro Bromonaphthine.*—Obtained by treating bromonaphthine by nitric acid. Formula: $C^{40}\,H^{10}\,Br^2\,X^2$. *Carminaphthine.*—Obtained by treating naphthaline by a mixture of bichromate of potass and sulphuric or hydrochloric acid; is of a fine rose colour; soluble in alkalis, from which it is precipitated unchanged by acids. Formula seems to be: $C^{38}\,H^8\,O^8$. Finally, the author, after proving the impossibility of the formulas indicated by M. Kolbe, of the compounds obtained by the action of chlorine and the alkalis on the sulphuret of carbon, concludes by stating, that these acids ought to be considered as composed of sulphuric acid, with marsh gas or its compounds, and that the formulas are (*formène* indicating the marsh gas):

Sulphoformic acid, $C^4\,H^8 + 2SO^3$ corresponding to $C^{40}\,H^{16} + 2SO^3$.

Chloruretted sulpho-formic acid, $C^4\,H^6\,Cl^2 + 2SO^3$ corresponding to $C^{40}\,H^{16}\,Cl^2 + 2SO^3$.

Bichloruretted sulpho-formic acid, $C^4\,H^4\,Cl^4 + 2SO^3$ corresponding to $C^{40}\,H^{12}\,Cl^4 + 2SO^3$.

Trichloruretted sulpho-formic acid, $C^4\,H^2\,Cl^6 + 2SO^3$ corresponding to $C^{40}\,H^{10}\,Cl^6 + 2SO^3$.

Academy of Sciences. Sitting of the 20th of July. Mr. E. de Beaumont in the chair.

Remarks on some new Phosphuretted Products; by M. P. Thenard.—In passing the hydrochlorate of methylene through an excess of phosphuret of lime at a temperature varying from 356° F. to 572° F. five products are obtained, three liquid and two solid. One of the former examined by the author was found to be composed of phosphorus, hydrogen, and carbon; it is a true alkali, as it restores the blue colour of litmus paper, reddened by an acid, and combines with acids to form neutral salts; it is colourless; hot and bitter to the taste; odour somewhat similar to ammonia; boils between 104° and 106° F.; density of its vapour 2·61—a number in all probability too high on account of the presence of a proportion of oxygen; distils without being decomposed; when exposed to a current of atmospheric air it absorbs oxygen with emission of light and forms a peculiar acid, which uniting with the undecomposed portion of the alkali, produces a salt which crystallises in fine transparent needles, in which the acid becomes at length in excess; explodes when mixed with oxygen; very slightly soluble in water, on which it floats like oil; analysed by treating it with the oxide of copper, it gave—

1st. Ex.	Carbon 46·1	Hydrogen	11·6	per cent.
2nd. Ex.	„ 46·08	„	11·7	„

It was impossible to say the precise quantity of phosphorus contained in it; the formula may, however, be expressed thus—$C^6\,H^9\,P$ divided into $C^6\,H^6$ and PH^3, contains no oxygen. The other two liquids are composed of the same elements; one is of a light yellow; viscous, inodorous; very dense; not easily volatilised; not acted upon by air at the usual temperature; insoluble in water and most acids, except the hydrochloric; probable formula, $C^4\,H^4 + PH^3$. The other colourless, smell somewhat like that of *cacodyle*, takes fire when exposed to the air; formula, $C^2\,H^2\,P^2\,H$, that is to say, three compounds of hydrogen and phosphorus, $P^2\,H$, PH^2, and PH^3; combines the first with $C^2\,H^2$; the second with $C^4\,H^4$; and the third with $C^6\,H^6$. As to

the two solid compounds, the one is the hydrochlorate of an alkali; the other not yet perfectly known is easily obtained by adding an excess of lime to the phosphuret of lime, it crystallises in beautiful white needles.

Liquid and Gaseous Ammonia.—The principal products aro, an amide (denominated by the author chloro-carbéthamide) chloride of ammonium, an ammoniacal salt, and some secondary products, among which is paracyanogen. The first presents itself in lamellæ; is fusible; volatile; very sweet taste; very soluble in alcohol; less so in water; mixed with an alkali, it does not disengage ammonia, but does so in abundance if boiled in an alkaline solution: formula—$C^{10}\ Cl^{7}\ H^{6}\ Az^{3}\ O^{8}$. Liquid ammonia, after some time, changes it into an ammoniacal salt: formula—$C^{10}\ Cl^{7}\ Az\ H^{2}\ O^{6}$, $2Az\ H^{4}\ O + 2HO$. This salt ought to be called chlorocarbethamate of ammonia; and the acid chlorocarbathamic; it is very bitter; crystallizes in white spangles; greasy to the touch; soluble in ether, alcohol, and water.

On the Composition of the Acids of Phosphorus; by M. O. Wurtz.—The conclusion of the author's researches is, that these acids originate in the same type, represented by anhydrous phosphoric acid, or by perchloride of phosphorus. Phosphorous acid is phosphoric acid, in which an eq. of oxygen is replaced by an eq. of hydrogen; and in hypophosphorous acid, two atoms of hydrogen are substituted for two of oxygen. In this memoir the author gives the result of his researches on the hyposulphites; in a second he will study phosphorous acid and the phosphite, and in a third the reaction of the protochloruret of phosphorous on ethero-phosphorous acid; amylophosphorous ether, and amylophosphorous acid. *Hypophosphites* are obtained by double decomposition of the soluble sulphates and the hyposulphites of barytes, and are in general combined with the elements of two eq. of water. The author then gives in a table the result of his analyses (hypophosphorous acid being composed of phosphuret of hydrogen and oxygen, formula $PH^{2}\ O^{3}$) of several hypophosphites, and terminates by some theoretical considerations.

On the Action of Chlorine on the Cyanuret of Mercury; by M. Bouis.—The author studied anew the influence exercised by chlorine on an aqueous solution of cyanuret of mercury when exposed to the rays of the sun. M. Gay Lussac was the first who stated that a liquid was thus produced, but without making it the object of his studies: M. Serullas indicated its composition, but without explaining all the reactions obtained. M. Bouis recommenced these researches, and thinks that three varieties of solid chloruret of cyanuret of mercury ought to be admitted; the first, monochloruretted; the second, bichloruretted; and the third, trichloruretted.

On a New Series of Acids; by M. Fremy. Memoir read.—The author communicated the continuation of his researches on a new series of acids formed of oxygen, sulphur, hydrogen, and nitrogen, which he calls sulphazotised compounds. In causing a current of sulphurous acid to pass on the azotite of potass, with the aid of water, eleven new acids were obtained which presented very extraordinary reactions.

Academy of Medicine. Sitting of the 22nd of July. M. Caventon in the chair.—The prefect of police addressed a letter, asking whether leeches which had been applied to individuals affected with contagious diseases, may be reapplied without danger after having been properly purged.

Dr. Theophile Roussel writes, claiming the priority of the discovery of pellagra in Paris, erroneously attributed to another individual: at the same time he presents a copy of his work just published on that affection.

Election of Foreign Associates; seventy-two votes; majority 37. Dr. Marshall Hall (London) obtained 49, and M. Arendt (St. Petersburgh) 37; and were declared duly elected; the third associate will be nominated at the next sitting.

On Clastic[1] *Anatomy.*—M. Renault, professor at the Veterinary School, Alfort, read a report on the model of a horse, presented by Dr. Auzoux, on the 16th of April, 1844 (vide *Medical Times*, vol. x. p. 73). The model is that of a small horse, about three feet nine inches and a half in height; the skin is removed; the musculi cutanei are preserved, and, when taken off, the animal appears as if flayed; it is so constructed that on one side all the constituent parts can be removed layer by layer, so as to expose successively the numerous organs which constitute the anatomy of the horse, the peculiar shape of the muscles, the relation they bear to each other, the vessels and the nerves which cross them and penetrate into their interior, and the precise spot of their insertion. When all these muscles are removed, the ligaments of the articulations may be seen, the cartilages which form a prolongation to certain bones, and especially the layers or thick cords of the yellow elastic tissue, so imperfectly developed in man, so abundant in the large herbivora, in one place attached to the occiput and the spinous processes of the cervical vertebræ so as to support the head; at another, forming a strong layer under the abdominal muscles, so as to form an efficient support for the viscera contained in the abdomen, and at the same time by its extensibility permit the enormous dilatation of the stomach and intestines, even when most distended. The reporter next noticed some slight modifications in the foot, the arteries, veins, and nerves, expressing a wish that the theca vertebralis, like the cranium, could be opened throughout its whole extent, the more so, as in the herbivora, and especially the horse, the spinal marrow is the reverse of what it is in man, being in proportion more voluminous than the encephalitic mass; and then continues:—In order to expose to view the splanchnic viscera, a horizontal section was made extending from before backwards so as to divide the thoracic and abdominal cavities into two parts of unequal size: the upper half could be raised like the cover of a box, the hinges being placed near the buttocks, so as to show the colour and shape of the organs contained in the cavities, and their relations with each other. But this is not all; these important viscera may be removed one by one, so as to permit our studying their peculiar forms, and even by sections properly made their internal structure may be examined; it is thus that the two aspects presented by the mucous membrane of the stomach, according as it lines the right or left side of the organ; the insertion of the œsophagus in the centre of the little curvature, the thickness of the muscular membrane around this spot explaining why vomiting is so uncommon in the horse may be shown. Similar sections were made for the heart, the lungs, the fossæ narium, the fauces, demonstrating in this last preparation that it is owing to the length of the epiglottis, in the rare occasions in which this animal vomits, the substances ejected pass through the nose rather than the mouth.

The model may be separated into upwards of two hundred pieces, which may be detached and replaced in less than ten minutes, and Dr. Auzoux in making it has performed a highly valuable object, for he has filled up a hiatus pointed out by the illustrious founder of our veterinary schools—a hiatus which he endeavoured to fill up by causing a series of anatomical plates to be published in 1779, under his own eye, by Goif. And what these two artists accomplished in drawing, Professor Reverchon, of Lyons, performed in 1822 and following years, in an anatomical point of view, by publishing a number of well-executed coloured plates on the osteology and myology of the horse. But before him, a modest and talented man, Brunot, after long and persevering studies for many years at Alfort, made models of horses of different sizes, and several limbs as large as life, in plaster. Is it necessary to state how superior the preparations of Dr. Auzoux are to what has just been mentioned, as well as to the anatomico-surgical plates drawn by Chasal, in 1828, under the direction of Professor Trousseau and M. Leblanc, and at a still later period by Professor Rigot? Finally, though this model does not render dissection useless, still it may be advantageously had recourse to when the professor wishes to call to mind any part of the body; by persons who breed or educate horses, and by savants who like to study the organization of animals throughout the whole series of beings. Consequently the committee propose:—1. To thank Dr. Auzoux for this new and interesting communication. 2. To advise him strongly to persevere in the excellent direction he has hitherto taken. 3. To draw the attention of government to this preparation, and to request its being presented to all the establishments in which the horse is the object of study. 4. To place his name on the list of candidates for the first vacant seat in the Section of Anatomy. Dr. Bouvier remarked that it was the prerogative of the Section of Anatomy to choose the list of candidates in case of a vacancy, and that therefore no name could previously be placed on the list. Dr. Nacquart was of the same opinion. M. Renault stated that this wish had already been expressed, and that it did not oblige the Section to retain the name. The conclusions were then adopted.

[1] *Clastic*, from κλάω, to break.

PROGRESS OF IRISH MEDICAL SCIENCE.

(FROM OUR OWN CORRESPONDENT.)

Dublin, Aug. 2.

Retrospect of Cases treated during the past Month; with Clinical Observations by M. Stapleton, Esq., M.D., F.R.C.S.I., one of the Surgeons to Jervis-street Hospital.

In taking a review of the cases under my care in the course of the month of July, gentlemen, I shall first direct your attention to that of Nelson, who suffered an extensive laceration of the great toe, with fracture of the two last phalanges. I did not see him on the occurrence of the accident, and when I got charge of him there was a nasty, ugly-looking slough all round the side of the toe, to hasten the separation of which, as you are aware, the application of warm dressing was employed; if the man would have but submitted, the best practice to have adopted would have been the removal of the toe at the junction of the first and second phalanges; and the propriety of such a course you will readily recognise by contrasting the case with that of the man from whom, within the last fortnight, the third phalanx of the little finger was removed for a somewhat similar amount of injury, the parts in this latter case having been so bruised that there was no chance of union by the first intention, while, by the performance of the operation, the man was enabled to leave the hospital in a few days with the wound nearly healed. In amputation of the fingers, you are recommended to do so at the joints, as the easiest method; but you will find a considerable advantage to arise from not always adhering to this rule, particularly in the case of the great toe, where, by keeping a portion of the phalanx, you preserve the attachments of some of the small muscles, and thereby assist the toe in its office of buttress to the arch of the foot.

The next case, one of compound comminuted fracture of both bones of the leg, with laceration of the integuments, was handed over to me, and notwithstanding the attention of his former surgeon, necrosis took place, followed by exfoliation of several small portions of bone. In looking at the limb, you would have expected the necrosis to have been more extensive, and that very large pieces of bone would have been thrown off; such was not the case, however, and the degree of deformity, for a case that looked so badly, promises to be trifling.

In the next case, one of simple fracture of both bones of the leg, you observed that there was considerable effusion with the formation of large vesicles; these you should treat by passing a needle and thread across them, by which means you give exit to the fluid and leave a covering for the parts beneath. I recommend you to use this in preference to worsted, which some advise, for in using the worsted you are apt, without a good deal of caution, to drag away the cuticular covering.

A considerable amount of fever attended this case, for the removal of which proper measures were had recourse to, but notwithstanding the strictest care in adaptation, very little callus has been thrown out. This, you know, sometimes arises from want of tone in the system, but in this man a tendency was given to separation of the upper fragment, from his having been in the habit (finding matters a little uncomfortable) of propping up his body with pillows borrowed from the neighbouring patients—a practice which also tended to thrust the bone through the integuments. Since measures have been taken to prevent the patient thus disturbing the apparatus,

and the limb been kept in the horizontal position, he has gone on much more favourably.

The next man, Ford, came in with œdema of the foot, for which he has been very nicely bandaged from the toes up to the knees. On examination, two small ulcers, about the size of a pea, and rather healthy-looking, occupied that part of the leg at which the tendo-Achilles arises. He stated that, about a year and a half ago, a loaded dray passed over his leg, since when he had never been well, though an inmate of two or three hospitals. Wondering how these small ulcers could have been productive of so much inconvenience, I examined the limb carefully, and, by the introduction of the probe, found that the ulcers just mentioned were at the termination of a fistulous canal, which, being slit up, led to a depot under the strong fascia of the leg; the deep-seated matter which had formed here not having been able to effect its escape, continued burrowing until it made its appearance where the fascia becomes united to the tendo-Achilles. All this mischief had escaped the notice of the medical men under whose care he had previously been. Having slit up the canal, I rubbed the floor of the sinus with nit. argenti, dressed it from the bottom with lint, and the case now goes on most satisfactorily.

We now come to the case of Brennan, who had his hand crushed by a horse running away with him. The little finger was extensively lacerated and broken, together with fracture and denudation of three metacarpal bones; the flap torn up by the accident was laid down and adjusted with sutures; but the great injury which the little finger had sustained rendered amputation of it necessary. The limb was then placed on an inclined plane, and every possible means adopted to repress inflammation, which in this case you might expect to run very high; our efforts have not, however, been as successful as could have been desired, for I yesterday pointed out to you a red line extending along the arm, indicating the existence of angeiolencitis, and this morning the inflammation, in its further spread, has assumed the character of true erysipelas. The traumatic fever is running to a considerable height, and means have been taken to prevent its further progress by leeches, &c.

The boy in No. 3, with white swelling of the knee joint, on whom Dr. Woodroffe performed subcutaneous section of the hamstring tendons, is suffering a great deal. There is undoubtedly ulceration of the cartilages, but we have some hopes of saving his limb by keeping up his constitution. He is taking a grain of quinine and two of sulphate of iron three times a-day, together with syrup of iodu-ret of iron, by which means the hectic symptoms have been very much subdued.

The limb has latterly been much easier, and bears to be moved slightly without pain; but these causes are so subject to changes and relapses that the issue of this case is as yet very doubtful.

If it be possible to preserve the limb, and save the boy from mutilation, the act will be a much more glorious one than that of removing the leg, however skilful the performance of the operation.

The man on whom I practised the operation of circumcision had phymosis to so great a degree as to have impeded materially the power of micturition, and to have prevented his being able to clean round the corona of the glans penis. I shall not now, however, go into a detail of cases in which this operation is required.

We now come to the man who met with the accident on Saturday last, while fastening one of the large Liverpool steamers, his leg having been caught between the hawser and pillar. The parts were so broken up that I saw there was no use in attempting to save the limb. The tibia was broken at the lower third, and denuded from below the ankle to within a hand's breadth of its superior extremity. The fibula was shattered in bits, and the soft parts with their tendons extensively lacerated. A consultation having been summoned, the immediate necessity of the operation was determined. I do not mean to enter into a history of amputations, which belongs more properly to a surgical course, but would just direct your attention to one remarkable circumstance connected with this subject; it refers to the use of the ligature, which was first introduced by Ambrose Paré, in the reign of Louis 16th, and with respect to the use of the flap operation, which I adopted in this instance, it was first attributed to Verudin, of Amsterdam, but properly belongs to Lourdon, of Oxford, who was the first to perform it, under circumstances like the present, below the knee.

Among the causes that render amputation necessary is malignant disease. When you have determined a limb to be so affected, the sooner you remove it the better, for the system soon becomes contaminated by its presence. Again, tumours sometimes arise, which, though non-malignant, often require removal, from the inconvenience they produce. In cases where mortification sets in, a question arises whether you are to operate or leave them to nature. I have seen instances of this kind in which nature performed a cure, and left a stump decidedly not inferior to some of those seen after the best operations. One case, which recurs to my memory, though of old standing, is remarkably illustrative of this fact. A girl had her fore-arm broken, and applied for surgical assistance, but the splints were applied so tightly that mortification was the consequence, and was with great difficulty arrested above the insertion of the deltoid muscle. The friends of the patient would not allow amputation, and on subsequently dressing the limb, I moved the bone, which, to my great surprise, separated at the epiphysis. In a few days after I introduced my finger into the wound, and removed the head of the bone. But suppose mortification to take place in the middle of a limb, it is very doubtful whether a sufficient covering for the bone would be left, and if you would not have a conical or sugar-loaf stump, with extensive caries, and necrosis, and various other lesions which we shall not go into the consideration of here, but which might also be enumerated amongst the cases in which the operation is occasionally required.

Had the species of injury which called for amputation in the case under consideration occurred in a boy of twelve or fourteen, I should have been strongly inclined not to have operated, but to have run the boy's youth against the risk arising from the extensive suppurations which would have been established. The much greater vascularity of the bone, in the case of the boy, would most likely have preserved it from death—a circumstance which must inevitably have occurred in this man had he been left to nature. I chose the flap operation in this case in preference to the circular incision, because I think below the knee it affords a better stump; the bones are better covered, and the nerves are not involved in the cicatrix, which is a source of considerable subsequent pain and irritation; besides, you avoid by it all chance of protrusion of the bone. While operating I stood at the outside of the limbs, and pushed the catling in at the outside also—a mode of proceeding by which there is much less danger of passing the blade between the bones. If, in addition, you use the precaution of pressing the thumb against the fibula, you are sure to pass the instrument out at the tibia; but in entering it upon this bone, you are very likely indeed to pass it into the interosseous spaces. The surgeon not unfrequently finds that, after cutting his flaps, he has not calculated sufficiently largely—a source of considerable disappointment, and to obviate the recurrence of which, Graef used to recommend the skin to be well drawn up, and the leg to be flexed a little, while the flap was being made. I am not an advocate for complicated dressings, and in order to avoid secondary hemorrhage prefer not bringing the flaps together for a couple of hours after the operation.

PROGRESS OF ENGLISH, ITALIAN, AND AMERICAN MEDICAL SCIENCE.

[The following comprise the principal articles of interest to our readers in a number of the *Medical Gazette*.]

Perforation of the Stomach.—A case of perforation of the stomach which had occurred in the practice of Dr. Barlow, of Guy's Hospital, is published by him. The patient was a woman, 59 years of age, who for eighteen months had suffered from obscure pains in the epigastrium and left side, darting through to the shoulder blade, and from occasional vomiting. These were at first treated as dependent on irritability of the stomach, caused by intemperance, and afterwards as sub-acute gastritis, and with some relief for a time, so that she left the hospital. While engaged afterwards in her domestic duties, she was suddenly seized with intense pain in the left side and shoulder, and great difficulty of breathing. These symptoms continuing, she again became a patient at the hospital, where she was treated for sub-acute gastritis, probably complicated by pleurisy. A day or two after admission, as she still complained of pain in her side, though it had greatly abated, her chest was examined, and the following results were obtained. Thorax upon percussion was moderately resonant both in front and behind, except under the left scapula, where it was rather dull. On applying the ear to the chest anteriorly, the respiratory murmur was audible, as also posteriorly on the right side, but not increased in this situation. About two or three inches below the left scapula and near the place of dulness, amphoric respiration was distinctly heard, synchronous with the movements of the lungs. It could also be traced down nearly as far as the loins. Metallic tinkling was also occasionally heard in this spot. Over the scapula, and of course above this last-mentioned point, egophony was heard, or, more properly, Punch's voice, for the words which she spoke were highly harsh and discordant. There seemed to be no obvious difference in the size or motion of the two sides of the chest. No pleuritic rubbing could at this time be detected. Sometimes splashing was heard on succussion, but this was not constant. The epigastrium presented rather an elevated bulky appearance, and was very resonant upon percussion, as was the whole abdomen. The remedies she took alleviated the vomiting and the pleurisy which she evidently laboured under, but she gradually sunk, and two days before she died, she sat leaning forward in bed, resting her head upon a pillow in front of her, and referring all her pain to the epigastrium. The examination of the body was made thirty hours after death. On opening the chest and abdomen, the first thing that presented itself was a large peritoneal abscess occupying the left hypochondriac region. It was circumscribed by adhesions which had previously been formed, and was thus separated from the general peritoneal cavity. It was bounded above by the diaphragm, which was very much forced upwards. Its front and side were formed by the ribs, and its lower boundary by the left lobe of the liver, spleen, and superior part of the stomach. The abscess communicated by two openings with the stomach. It was lined by a membrane which was partially sloughing, and involved the adjacent parts of the liver and spleen. It contained a dark offensive fluid, full of broken-down membrane, and also some air. On the mucous membrane of the stomach were some red patches, and close to the œsophageal opening on the right side was a perforation, the result of the ulcerative process, communicating with the above-named abscess, and large enough to admit the middle finger. On the anterior wall of the stomach there existed another perforation, but not so large as that just described. When the chest was opened a large quantity of sero-purulent fluid escaped from its left side. No pleuritic adhesions existed, with the exception of one or two unimportant bands of lymph. The lungs were very much condensed from the pressure of the diaphragm, which was forced up as high as the fourth rib. With this exception, they were healthy: no tubercles could be discovered. The heart was healthy, and there existed no traces of pericarditis, neither recent, nor of an older date. There existed no communication between the chest and abscess. The indications of pneumo-thorax which were discovered by the stethoscope, are attributed to the passage of air, by the pressure of the diaphragm from the cavity of the abscess into the stomach, and *vice-versâ*. The egophony was produced by the effusion of fluid into the cavity of the chest, from the pleuritic inflammation.

Spermatorrhœa.—Mr. B. Phillips, in a communication entitled "Further remarks on spermatic discharges," gives the results of a rather extensive experience on this disease. It appears that he has seen 109 cases in rather more than two years, and he says that the cases which have come under

his notice have left on his mind the impression, that though great general depression, and much mental discomfort, are the common accompaniments of those discharges, the instances are unfrequent where permanent bodily or mental mischief results from them: still he has known cases in which the mind as well as the body has broken down under the complaint. Usually, however, the inconvenience is got the better of; owing more commonly to effort on the part of the patient, than to the skill of the attendant. Of the 109 cases, eighty-four were under twenty-two years of age; ninety-seven admitted that they had practised masturbation to a greater or less extent, and they referred their present distress to that practice. Every one, however, stoutly asserted that the habit had been discontinued—by some for a few months, by others for years—but in many cases there were reasons to doubt the correctness of the assertion. In two of the older cases, irritation within the rectum was the exciting cause; in two instances abuse of sexual intercourse; in one, probably in two, stricture of the urethra; in four, the irritation consequent upon congenital phymosis. In the remaining cases there was no doubt that masturbation was practised, though it was strenuously denied. In thirty-eight cases the patients were submitted to active treatment; caustic was applied upon the urethra. In seventy-one instances no medical treatment seemed to be necessary, except for the purpose of exercising some moral influence over the patient, and to gain time. They were advised in many instances to use a mixture of the Tinct. Ferri Sesqui-chloridi, and Tinct. Lyttæ, and in those cases where the patient was reasonable, Mr. Phillips tried to convince him that it was unnecessary to employ any medical treatment. The ordinary characters of the disease are the involuntary emission of semen during the night, occurring during lascivious dreams; and the escape of a drop or two of a viscid transparent fluid, with the last drops of urine, either when simply emptying the bladder, or when at stool. This kind of loss very commonly produces severe mental depression, often amounting to absolute hypochondriasis. The way in which Mr. Phillips explains this kind of discharge is as follows:—A large number of lads soon after puberty inflame their minds by reading lascivious books, from which they derive images of sexual pleasures. A large number, also, are early taught the practice of masturbation. Under both circumstances, the gratification derived by contemplating the image on the one hand, and by the physical excitement on the other, keeps up a constant irritation. The testicles, instead of enjoying moderate rest, are incessantly stimulated by the dream at night, the mental or physical stimulus during the day; the secretion is constant, the seminal vesicles are distended, and unless the ejaculation takes place with sufficient frequency to relieve them, the fluid must escape by some other means; and the pressure upon them during the efforts at stool, or in making water, squeezes out a certain quantity of the fluid by which they are distended, and it usually escapes with the last drops of urine. At one time he doubted whether this fluid were spermatic, it is usually so smooth, transparent, and homogeneous; but if it be examined under the microscope, spermatozoa can generally be observed in it. Its thin fluid character has induced some people to think that it was a depraved secretion, become watery by exhaustion of the secreting organ; and sometimes it may be so, but usually it is not; for if a person who complains of a constant escape of the thinner fluid has an ejaculation, the fluid will be thick and grumous. It is therefore most probable, that the more fluid portion of the secretion which fills the seminal vesicles is most easily pressed out; and this is a reasonable explanation of this particular feature of seminal discharges. Mr. Phillips recommends for the cure of this symptom, the keeping the testicle quiet, by substituting new images for the prurient fancies which have occupied the mind, and emptying the vesicles occasionally by sexual intercourse; for which latter purpose he recommends marriage. The influence of the mind in destroying the virile power is very great, and it is equally necessary to exert an antagonising mental influence to rouse the energies, and control the disease.

Cyanosis.—Mr. A. S. Taylor details the following appearances as presented at the post-mortem examination of the body of a woman, aged 45, who died suddenly in the hospital. She had laboured under cyanosis all her life, and was supposed to have been destroyed by a poisonous dose of nux vomica. The pericardium contained a considerable quantity of clear serum. The heart was greatly enlarged, its increase of size being entirely due to the state of the right cavities. The pulmonary artery was very conspicuous; there were some white patches, like cicatrices, upon its left side; and its back part adhered to the aorta by strong bands. The right cavities of the heart were distended with dark semifluid coagula. The right auricle was very capacious, and communicated with the left by an oblique opening capable of transmitting the ends of three fingers. In the remains of the septum, below this, was an oblique passage, closed on the side of the left auricle, and evidently the trace of a foramen ovale. It was clear that there must have been originally two of these communications, one of which had closed, the other remaining permanently open. The four pulmonary veins opened into the right auricle. The common termination of coronary veins occupied its usual position, and was furnished with a complete valve. The tricuspid valve was natural; the right ventricle extremely capacious, and its walls thick. The pulmonary artery was of extraordinary width; the tissues of the vessel were strong, and still extensible. The sigmoid valves were considerably thickened, and had some vegetations attached to their free edges; notwithstanding the extreme dilatation of the artery, they doubtless acted as efficient valves. The left auricle was smaller than the right. The left ventricle was remarkably small in comparison with the right; its walls were thick, but their muscular tissue was not strong. The aorta and its valves were healthy in structure; but this vessel was remarkably narrow, being less than an inch and a half in circumference at the widest part of its orifice; and distal to the left subclavian artery it was very perceptibly narrower than elsewhere. There were several enlarged bronchial glands near this spot, which may have encroached slightly upon the aorta; or the dilated pulmonary artery may have somewhat compressed it; but there was no distinct stricture here, and the contracted state of the left ventricle and ascending aorta proved that this narrowing had not caused much impediment to the circulation. The whole remaining tract of the aorta was nearly free from deposit, but very singularly narrow. Neither the internal mammary nor the intercostal arteries presented any obvious enlargement. The lungs were, in parts, highly emphysematous, and were generally much congested, as was also the liver. The chest was much deformed, apparently from tight lacing. The contents of the stomach were examined chemically; but no traces of nux vomica, nor of any other poison could be discovered, and Mr. A. S. Taylor referred the death to the delay occasioned to the passage of the blood in the right cavities of the heart.

Dyspepsia from Over-Eating.—Dr. Dick says, over-distension of the stomach frequently repeated overcomes the resiliency of the muscular coat. A species of muscular impotence ensues; the food lies comparatively motionless in the flaccid organ, and the important process by which the gastric juice is mixed intimately with the food, and brought in contact with the surfaces of the minutest fragments, is very imperfectly effected. Hence, just in proportion to the degree and permanence of over-distension of stomach, is digestion tardy and imperfect, and as food, not transmitted downward, in due time, acts in consequence of chemical changes and accumulations, as a morbid stimulant, various untoward consequences arise. Over-distension and its ill effects may not be confined to the stomach, but excessive meals may extend their disastrous consequences over the whole alimentary canal. An alimentary mass larger than the system requires, and than can be duly digested, distends, in turn, the duodenum and small intestines (interfering, meantime, with the free excretion of the liver by the common duct), and, in consequence of the flaccid condition apt to be induced in the parts now named, impactions of the duodenum, and scybalous accumulations in the small intestines, frequently occur. Another hurtful consequence of large, frequent, and stimulant meals, is the production of permanent hyperæmia of the mucous coat of the stomach, than which state nothing interferes more with the function of a secreting surface.

The Pancreas.—In an article on the various forms of dyspepsia, Dr. Dick thus speaks of this organ:—Though we are, in a great measure, ignorant of the precise uses of the pancreas, yet there can be little doubt that it performs a part in the process of digestion. Dr. Baillie mentions a case of abscess of this organ, in which the symptoms before death consisted in wandering abdominal pains, in spasmodic affection of the abdominal muscles, in squeamishness, in stomachic distension. Disease of the pancreas may simulate, or rather be mistaken for, affections of the stomach, or of the left lobe and convex surface of the liver. It frequently causes epigastric pain and sickness, and sometimes jaundice, when structural disease, extending along its duct, involves the ductus choledochus, narrowing or obstructing that common conduit. Its enlarged bulk may also be detected through the stomach, and be mistaken for structural disease of that viscus; or else pressing on the ductus communis, or the duodenum, may cause obstruction of the former, impaction of the latter.

Leucorrhœa.—Dr. Allnatt mentions a case of leucorrhœa, very imperfectly detailed, in which it seems that some relief was experienced from the use of the oxide of silver.

Scirrhous Stricture of the Colon.—A case of intestinal scirrhus occurring in the person of an aged female, is reported from Guy's Hospital. The disease apparently commenced at the umbilicus, where it formed a soft and elastic tumour, about the third of a hen's egg in size, which gradually became harder, of a bluish or purple colour, and very painful. Suppuration afterwards took place, followed by discharge of unhealthy pus, mixed with blood. The bowels were also costive, and there was general abdominal tenderness. After her admission into the hospital, tumours were discovered extending from the epigastric by the left hypochondriac region. Fæcal vomiting next occurred, and afterwards hæmatemesis. Meanwhile the abdominal tumors continued to extend, and the strength declined; she died nine weeks after her admission into the hospital. The following is the account of the post-mortem appearances, as furnished by Mr. King. The lungs contained seven or eight round, coarse, reticular, creamy tubers, the size of nuts; an undefined scirrhous state of parts at the umbilicus; some adhesions about the liver and gland below. The left end of the arch of the colon was contracted and dense; from this there was a wide opening into a slough cavity, the size of an egg, hard and contracted, with a simple, free, sinuous canal into the stomach, near the mesian line. Tubercles occupied the left lobe of the liver, the size of a child's head (with a partial coating of peritoneum, half an inch thick, even and semi-transparent) radiating, dissolving; watery and numerous tubercles in the liver, and about the described parts; also in, on, or about the uterus, scattered as beans. The cœcum only was distended. The ileum was large, the serous surfaces injected and gray.

Congestive Apoplexy.—Mr. French narrates the particulars of a case of congestive apoplexy occurring in a little girl, between two and three years of age, which terminated fatally. Prior to death, certain appearances seemed to indicate mischief in the abdomen, and after death, the cardiac extremity of the stomach was found to be perforated by an aperture of about three inches in diameter. It presented a wide, open, irregular laceration: the edges, soft, thin and membranous, running into shreds like those observed in spontaneous perforations of this organ. There was no thickening of the coats of the stomach in any part, nor any appearance of disease,—in one or two patches near the aperture, the coats appeared to be slightly thinned. The mucous membrane forming the edge of this aperture was of a dark bluish black colour. There was only a thin layer of mucus on the stomach, no solid or liquid matter, nor any appearance of food. It seems that only a small quantity of tea was administered in the twenty-three hours during which the child survived the attack, but it is doubt-

ful, from the account given by the parents, whether even this was swallowed. There were no traces of the meal which the child had made, three hours and a half before its seizure; a fact further established by iodine water having no effect upon the contents of the organ. Nothing appeared to have escaped from the aperture; there was no sign of extravasation, no mark of peritoneal inflammation, nor any softening of the spleen or surrounding structures in the neighbourhood of the perforation. The mucous membrane, it should be observed, was entirely free from any trace of inflammation. Mr. French examines the question, whether this was a case of death from poisoning or disease. The facts detailed, as well as the negative proofs derived from an analysis of the contents of the stomach, show that this could not have been a case of poisoning. The perforation might have been ascribed to a powerful irritant, like sulphuric or oxalic acid; for the blackened appearance of the mucous membrane at the aperture somewhat resembled the effects of these poisons; but, 1st, the symptoms did not come on until nearly four hours after the last meal taken, whereas these acids produce their effects immediately; 2nd, the symptoms were not those of an irritant poison; 3rd, there was no sign of inflammation in the stomach; 4th, no appearance of the presence of these two acids nor any other poison in the stomach. A narcotic poison might account for the symptoms, but not for the perforation; still, it is impossible to admit that a narcotic poison had been taken;—1st, the symptoms came on suddenly, and about four hours after the last meal; 2nd, there was no appearance of narcotic poison either by the odour nor by the application of tests. The supposition of poisoning, for these reasons, cannot therefore be admitted. With respect to disease, the principal question to be considered is whether the perforation of the stomach took place during life, and was the cause of the symptoms and death, or whether it was merely the result of post-mortem changes. The child had occasionally complained of pain in the region of the stomach, as of the sensation of a bone in her side after eating, but she had not suffered from any disease of the organ, and her appetite was good even up to her last meal. The symptoms and appearances are wholly unlike those observed in death from perforation of the stomach as a result of disease. In these cases the person is suddenly seized with the most violent and excruciating pain, vomiting, and other symptoms indicative of mortal collapse. The intellectual faculties are retained, and the individual dies from peritonitis. After death an aperture is found, commonly small, well defined, with thickened edges sometimes discoloured,—marks of disease in the mucous membrane (ulceration) in or near the seat of perforation,—extravasation of the contents of the stomach,—with the well-marked signs of peritoneal inflammation in the abdominal cavity. On comparing this description with that of the symptoms and appearances in the case of the deceased, they will be found to be wholly dissimilar. On the other hand, the perforation presented all the characters which have been assigned by pathologists to those spontaneously produced by chemical action, either after death or during the last moments of life,—as, for example, its situation at the cardiac extremity,—its size, occupying the whole of that portion of the stomach, —the thin, shreddy, pulpy, and blackened edges,—the absence of any sign of disease, as inflammation, ulceration, or thickening in the mucous membranes; all these are circumstances which appear to point to this, as the true explanation. It is perhaps somewhat unusual to find the stomach thus extensively perforated from spontaneous causes in so young a subject, and admitting the correctness of this view, it appears to show that for the production of spontaneous perforation, it is by no means necessary that there should be food in the stomach, or that a meal should have been made shortly before death. Death was ascribed to congestive apoplexy, an opinion founded on the symptoms, coupled with the highly congested state of the brain and its membranes.

Pericarditis connected with Rheumatism.—Dr. Taylor relates a case of sub-acute rheumatism occurring in a female servant, twenty years of age, which became complicated with acute pericarditis. The rheumatism was of some duration when she came under his care at University College Hospital, on the 1st of January, 1839, and the pericardiac disease had already commenced, as evinced by sharp pain under the left breast, increased by a deep inspiration, by coughing, and on pressure; a sense of weight about the heart, and some palpitations, with a frequent pulse. Auscultation was not carefully practised; but the heart's impulse was increased, and then was a double morbid sound. The treatment consisted of venesection repeated thrice, the exhibition of a full dose of calomel and opium, followed by half-grain doses of tartarized antimony, every four hours. By these means the pain was diminished, and the other symptoms relieved, but on the ninth day after admission, the pain still continued. The pulse was 108; respiratory murmur rather puerile everywhere in the right lung; audible in the upper part of the left lung, but in the lower part almost or entirely wanting. There was not any other morbid respiratory sound. She was cupped on the left side to eighteen ounces, and calomel and tartarized antimony exhibited every four hours. The report the next day was, respiration audible in every part of the left lung; heart's impulse not very strong, less than it was; rhythm regular; a double morbid sound, like a rough friction-sound; the second the louder, most distinct about the junction of the fifth costal cartilage with the left border of the sternum; nearly as loud over the third rib, and audible, more or less, over the whole region of the heart. The second morbid sound heard but feebly, at the top of the sternum; a slight morbid sound in the neck; healthy sounds audible nowhere. A single rough bellows-sound, synchronous with the pulse, heard along each side of the vertebral column in the greater part of its length, but loudest on the right side, opposite the fifth and sixth dorsal spines. It was distinctly audible over the whole of the back part of the chest, even at the axillary borders of the scapulæ, and also in the lumbar region. *Percussion* yielded a dull sound over too great an extent in the situation of the heart, but a natural sound over both lungs; pulse 80, soft and regular; tongue furred, and rather black. A light tonic was soon after prescribed, and, the mouth having become sore, the patient's health somewhat improved; but when discharged, the impulse of the heart was still too strong and too extended; there was dulness on percussion as high as the third rib only; and scarcely a trace of morbid sound over the heart or along the sides of the spinal column. In some remarks appended to the history of this case, Dr. Taylor observes that the chest was not examined for some time after the patient's admission into the hospital, both from the non-suspicion of the existence of any serious disease, and from the presence of hysteria, but subsequent experience has taught him the importance of remembering that although hysteria may be proved to exist, it does not follow that it is the *sole* disease. Cases of this kind frequently present considerable difficulty in diagnosis. It is often easy to perceive, for example, that pain in the abdomen is neuralgic, because it is increased by the slightest touch of the skin; but this is sometimes accompanied by a deeper-seated pain, which may likewise be neuralgic, but which may also be *inflammatory;* and both the general and local symptoms are such, that the diagnosis may for some time be not a little embarrassing. The general symptoms of the pericarditis were, acute pain under the left breast, increased in respiration, by coughing, or by pressure; a sense of weight or oppression about the heart; and palpitations. The pulse was frequent, and the heat of the skin was somewhat increased, but these symptoms were not urgent, and did not excite much notice. The complication of the pericarditis with pleurisy was also suspected, but was not fully ascertained from the non-practice of percussion. On admission, the heart's impulse was increased, and there was a double morbid sound. This, in the course of ten days, was found to be less; and the sounds were more carefully noted, when the question presented itself—were these sounds the result of pericarditis or of valvular disease? The general symptoms not being such as to afford much assistance, the diagnosis rested chiefly on the physical signs. Now we find—1st. That the sound was double, continuous, and rough, but, as was noted at the time, it would be difficult to affirm that, considered in itself, and apart from its situation, extent, and duration, it could be distinguished from many valvular murmurs. 2nd. It was heard extensively, and loudest at first, where valvular sounds are seldom loudest, and afterwards changed its point of greatest intensity to opposite the third rib. This fact (not mentioned in the history, and the date of which is not mentioned at all) agreed best with the notion that the pericardium was the seat of the sound, and seemed to indicate either adhesion, or, more likely, greater serous effusion. 3rd. The morbid sound was very loud over the third rib, and scarcely audible at the top of the sternum,—a circumstance which could hardly occur in aortic valve disease. On these grounds it was concluded that the sound was pericarditic, and it would cease in a few weeks—a prediction which was verified by the event. The phenomena subsequently observed proved that there was pericarditis. On the 24th, the morbid sounds were much less intense, and there was a dull sound, on percussion, as high as the second rib. On the 30th, the increased impulse is again noted, and a dull sound, as high as the third rib only. Now the fact that the dulness on percussion in the cardiac region reached, on the 24th, as high as the second rib, is sufficient of itself, Dr. Taylor believes, in the absence of disease in the lung, to enable him to say that the pericardium contained a liquid, and, taken in connexion with the diminished extent of dulness a few days later, it must be admitted to be quite distinctive. The friction-sounds, although feebler, still existed on the 24th, proving that they may co-exist with a certain amount of serous effusion in the pericardium. The single murmur at the back of the chest is a very remarkable feature in this case. Did it originate in the aorta or in the pericardium? Dr. Taylor thinks in the latter, for the following reasons:—1st. It was loudest about the fifth and sixth vertebræ, and therefore opposite to the heart. 2nd. The great *transverse* extent of the sound, without any evidence of disease of the lung to conduct it. 3rd. Its diminution on the 24th, when the friction-sound diminished, and when there was evidence of increased serous effusion into the pericardium. 4th. Its cessation with the friction-sound on the 30th. If this view be correct, it is remarkable that this sound was *single*, whilst the sound in front was *double*. Perhaps the single sound depended on a fibrinous exudation on the posterior surface of the pericardium, so disposed as to occasion a friction chiefly with the ventricular systole; considered in itself the sound resembled that occurring in disease of the aorta much more than the rubbing sound of pericarditis; but, independently of the considerations adduced above, it may be presumed that it would have been less likely to cease in the former than in the latter case. Signs of enlargement of the heart remained when the patient was discharged.

Ligature of the External Iliac.—A case in which this operation was successfully performed is recorded by Dr. Duncan in *The Northern Journal of Medicine*. The patient was a man, thirty years of age, an American sailor, of a stout robust frame, and full habit of body. The disease commenced in consequence of making a violent effort while reefing a sail, and was of some months' duration when he was admitted into the Royal Infirmary in Edinburgh, at which time the tumour was rapidly increasing in size. It measured six inches in length, and extended from about an inch above Poupart's ligament downwards. It was somewhat irregular on its surface, in consequence of some enlarged glands lying over it. It felt pretty resisting at all points, except over its upper and anterior part, where it was more compressible and most prominent. It pulsated, when grasped, in all directions; but the pulsations were felt most distinctly over its upper and anterior part. Over the same part an indistinct bellows murmur was heard, more particularly when the thigh was flexed on the abdomen. When the limb was extended so as to make the fascia tense, the tumour diminished somewhat in size; and a certain diminution could likewise be effected by pressure, and likewise by compressing the abdominal aorta so as to suspend the pulsation in the swelling. The integuments over the tumour were free from discoloration, were per-

fectly lax, and could be moved freely over it. There was no œdema of the limbs, and no congestion of the superficial veins. After the requisite preliminary antiphlogistic treatment had been practised, the vessel was tied. The patient was laid resting rather on his left side, with the shoulders slightly elevated and the limb somewhat bent. An incision dividing the skin and superficial fascia was made, commencing about an inch above the middle of Poupart's ligament, and carried upwards for about three and a half inches, in such a direction as to be when it passed the anterior superior spinous process, about an inch or more internal to it. It was slightly curved, the concavity being towards the mesial line. The aponeurotic expansion of the external oblique, the internal oblique, and transversalis, were divided to the same extent. The fascia transversalis was next divided to the requisite extent, the peritoneum carried inwards, and the vessel exposed. The thin fascia covering the artery was divided to a very slight extent, and the needle carried around the artery, with its convexity towards the peritoneum, counter-pressure being made with the forefinger of the left hand. As a small filament of a nerve lay over the needle along with the artery, another needle was passed from within outwards, the first being retained to serve as a guide. The vessel was then compressed over the needle, and immediately the pulsation in the tumour ceased. The ligature was secured, one end being cut close to the knot. The securing the ligature was followed by immediate cessation of the pulsations, and collapse, to a certain extent, of the tumour. The wound was brought together by several points of suture, and lint wetted with cold water applied. The patient was laid in bed, with the limb slightly bent, and supported by pillows at the knee. The patient scarcely had a bad symptom afterwards, except that some excitement was caused by a crowd of students around his bed at the visit the day after the operation, which was removed by an opiate antimonial draught. He was also bled from the arm the same evening. The ligature came away on the twenty-second day.

[The following are the principal articles of interest to our readers in two numbers of the *Lancet*.]

Fracture of the Thigh-bone.—Mr. Prior has narrated the details of a severe compound transverse fracture of the femur with displacement, which occurred in the person of a young sailor, who had fallen from the maintop to the quarter deck, a height of from seventy-nine to eighty feet. The fracture was reduced by his fellows in bringing him ashore. There were other and numerous injuries inflicted by the fall, such as contusions and lacerations, so that the whole body was more or less ecchymosed. The consequent shock was very great, on recovering from which the limb was placed on the double-inclined plane, and treated in the usual manner. Mr. Prior abstained from bleeding at any period of the treatment. The principal symptoms which presented themselves afterwards were those of muscular irritability, which for a time was very troublesome. The wound was examined, for the first time, about three weeks after the accident, and was found to be nearly closed. The fracture apparatus was removed five weeks later, and the man was allowed to walk about on crutches. In another month he was dismissed, walking well, with the limb not perceptibly shortened. In another case which Mr. Prior saw occasionally only, but which was not under his care, the fracture was oblique, and extended nearly to the condyles. The patient was several years older than the other, and of an impatient, irritable habit, yet did not suffer so much from involuntary muscular action as the former. The limb was placed in the straight position, but union did not make progress. The end of the upper portion of the bone in about a month gradually diverged outwards, forced its way through the integuments, and thus made the injury a compound fracture of the worst description. Profuse suppuration ensued at the end of seven or eight weeks, and amputation was performed, the patient dying thirty hours after. In this case the constitution never recovered from the original shock.

Fracture of the Spine.—Mr. Prior gives at some length the particulars of a case in which fracture of the spine occurred as a consequence of a fall from a ladder—from a height of thirty-four feet. The patient, a bricklayer's labourer, fifty-four years of age, complained of excruciating pain in the spinal column, more particularly about the eleventh dorsal vertebræ, which on careful examination afforded a distinct crepitus from fracture of the spinous process; there was also great pain from the gentlest pressure in the two vertebræ immediately above. Besides other bruises and wounds of minor importance, there was a prominent elastic swelling on the left dorsum ilii. The respiration was oppressed; no pulse at the wrist; the man could not pass his water, and the lower limbs were paralysed as to motion, but not as to sensation. Stimuli and anodynes were exhibited, and the water drawn off by the catheter. Reaction occurred but slowly, but the man by the third day recovered sufficient expulsive power over the bladder, so as not to need the use of the catheter. He suffered much from excessive cramps in the limbs, and from some symptoms of paralysis of the intercostal muscles; he was also delirious for a short time. The treatment already mentioned was steadily pursued, and cathartics were exhibited when required. Under this plan the man improved somewhat, so as to be able to lie on the back, and shortly after to change to the right side, and even to rotate the lower limbs slightly. The integuments over the lower dorsal vertebræ were pustulated by the tartar-emetic ointment, after which he was cupped over the seat of the injury, and mercurial frictions used; a few days later an issue was formed on each side of the spine near the lumbar vertebræ. During this while the man may be said to have gradually but steadily improved. At the end of more than two months the loss of voluntary motion over the lower extremities in flexion and extension constituted the only unpromising symptoms, but as he can rotate them freely when extended, Mr. Prior thinks there is reason to hope for further amendment. The treatment already described is to be persisted in. Another case of fractured spine which occurred on board the Inconstant, is also recorded by Mr. Prior. The injury resulted from a fall of about seven feet, and was followed by considerable collapse. The spinous process of the tenth dorsal vertebra was fractured. The principal symptoms very nearly resembled those already recorded, but the recovery of the patient when discharged from the ship, three months after the accident, was more advanced than in the first case, he being able to move about tolerably well by means of a crutch and stick. In both these cases in all probability the spinous process was alone broken, although it is not impossible that the posterior arch was also splintered, and thus some degree of pressure caused on the spinal cord. It is, however, very unlikely from the symptoms which presented, that any serious injury was done to the body of any of the vertebræ, although in the first case there were one or two rather suspicious symptoms. Even the partial recovery which took place could scarcely have been anticipated, had the vertebral bodies been fractured.

Strychnine in Chorea.—Dr. Ross mentions two cases in which he employed this alkaloid successfully in the treatment of chorea. The remedy was given in small doses. It is, however, a very dangerous experiment, and should not be had recourse to, until other means of cure have failed.

Apoplexy a Cause of Sudden Death.—Mr. Semple narrates a case of exceedingly sudden death, in which the only morbid appearances detected, were congestion of the membranes of the brain, of the lung, liver, and kidneys. The heart and its valves were healthy. The patient was a gentleman, fifty-five years of age, about five feet ten inches high, stout, but not corpulent, with a rather short neck, of moderate and regular habits, and generally in the enjoyment of perfectly good health. He was not known to have experienced any premonitory symptoms.

Variola and Scarlatina.—Mr. Barnes gives the particulars of a case in which these two exanthems ran their course almost simultaneously.

ORIGINAL RESEARCHES ON THE FRONTAL SINUSES, WITH OBSERVATIONS ON THEIR BEARINGS ON THE DOGMAS OF PHRENOLOGY.

By SIR WILLIAM HAMILTON, Bart., F.R.S., Secretary to the Senate of the University of Cambridge.

(Concluded from page 179.)

By the kindness of Dr. Monro and Mr. Mackenzie I was permitted to examine all the crania in the public anatomical museum, and in the private collection of the professor; many were, for the first time, laid open for my inspection. I was thus enabled to institute an impartial induction. A random measurement of above thirty perfect crania (laying aside three skulls of old persons, in which the cavity of the sinus was almost entirely occupied by a pumicose deposit) gave the following average result: breadth, two inches four-tenths; height, one inch and nearly five-tenths; depth (taken like Dr. Monro), rather more than eight-tenths of an inch. What in this induction was probably accidental, the sinuses of the female crania exhibited an average, in all the three dimensions, almost absolutely equal to that of the male. The relative size was consequently greater.

Before the sinuses of the fifty crania of Dr. Spurzheim's collection (of which I am immediately to speak) were, with the sanction of Professor Jameson, laid open upon one side, I had measured their three dimensions by the probe. This certainly could not ascertain their full extent, as, among other impediments, the probe is arrested by the septa, which so frequently subdivide each sinus into lesser chambers; but the labour was not to be undergone a second time, especially as the proportional extent of these cavities is by relation to the phrenological organs articulately exhibited in the table. As it was, the average obtained by the probe is as follows:—In the thirty-six male crania (one could not be measured by the probe), the breadth was two inches and nearly four-tenths; the height, one inch and nearly three-tenths; the depth, rather more than one inch. In the twelve female crania (here, also, one could not be measured by the probe) the breadth was one inch and rather more than nine-tenths; the height, nearly one inch; the depth, within a trifle of nine-tenths.

I should notice that in all these measurements, the thickness of the external plate is included in the depth.

So true is the observation of Portal, that the "*frontal sinuses are much more extensive than is generally believed.*"

The collection of fifty crania, of which the average size of the frontal sinuses has been given above, and of which a detailed table of the impediment interposed by these cavities to phrenological observation now follows, was sent by M. Royer, of the Jardin des Plantes (probably by mistake), to the Royal Museum of Natural History in Edinburgh; the skulls, taken from the catacombs of Paris, having, under Dr. Spurzheim's inspection, been selected to illustrate the development of the various phrenological organs, which development is diligently marked on the several crania. Thus, though I have it in my power to afford a greatly more extensive table, the table of these fifty crania is, for the present purpose, sufficient. For—

1st, They constitute a complete and definite collection;

2nd, A collection authoritative in all points against the phrenologists;

3rd, One to which it can be objected by none, that it affords only a selected or partial induction in a question touching the frontal sinus;

4th, It is a collection patent to the examination of the whole world;

5th, In all the skulls a sinus has on one side been laid open to its full extent; the capacity of both is thus easily ascertained, and, at the same time with the size of the cavity, the thickness and salience of the external frontal table remains apparent.

In these circumstances it is to be observed—

In the *first* place, that, as already noticed, while the developments of all the crania have been carefully marked, the presence of the frontal sinuses has been signalised only in one skull (the male, No. 19, xiv), in which they are, however, greatly below even the average.

In the *second* place, that the extent of the sinus varies indeterminably from an affection of one to an affection of sixteen organs.

In the *third* place, in this induction of thirty-seven male and thirteen female crania, the average proportional extent of the sinuses is somewhat less in the female than in the male skulls; the sinus, in the former, covering 4·4, and affecting 1·2 organs; in the latter covering 5, and affecting 2·1 organs. This induction is, however, too limited, more especially in the female crania, to afford a determination of the point, even were it not at variance with other and more extensive observations.

In the *fourth* place, the male crania exhibit at once the largest and the smallest sinuses. The largest male sinus covers 12 and affects 4; whilst the largest female sinus covers 7, and affects 3 organs: whereas while the smallest male sinus affects only one, the smallest female sinus covers 2 organs.

In the *fifth* place, so far from supporting the phrenological assertion that the sinuses are only found, or only found in size, in the crania of the old, this their collection tends to prove the very reverse; for here we find about the smallest sinuses in the oldest heads.

TABLE exhibiting the variable extent and unappreciable impediment, in a phrenological relation, of the Frontal Sinuses; in a collection of fifty crania, selected, and their development marked, under the direction of Dr. Spurzheim.

Number of Skull, as hereinarranged, according to sex and age.	Number of skull, according to Spurzheim's fortuitous order.	Sex, as marked by Spurzheim.	Age, as inferred from teeth and other criteria.	Extent of Sinuses, as entirely or nearly *covering* (†), or as more or less *affecting* (*), the pretended phrenological organs, according to the late and latest numeration. (1)

(1) The organs denoted by these numbers:—ix, 7, Constructiveness; xx, 32, Mirthfulness or Wit; xxii, 19 [2], Individuality, Lower Individuality; xxiii, 20, Configuration, Figure; xxiv, 21, Size; xxv, 22, Weight, Resistance; xxvi, 23, Colour; xxvii, 24, Locality; xxviii, 27, Calculation, Number; xxix, 25, Order; xxx, 19 [1], Eventuality, Upper Individuality; xxxi, 26, Time; xxxii, 28, Melody, Tune; xxxiii, 29, Language—this organ Gall divides into two, to wit, into the organ of Language and the organ of Words; xxxiv, 30, Comparison; xxxv, 31, Causality. The order of the numbers in this table was taken from that of a more extensive and general table; so that whilst here xx, 32, has not been affected at all, there it was affected more frequently than ix, 7.

ON INFANTICIDE.

By ORFILA.

(Translated for the Medical Times, by Dr. ROSENTHAL.)

In the month of January last I was requested by a professor at a medical school to give an opinion, as to whether it be possible to distinguish the ashes left behind by burnt wood, from those of a burnt new-born child. It seemed probable that a young female after having killed the child of which she had been lately delivered, had burnt the body by placing it on wood, ignited in a furnace, and it was supposed, that the judge commissioned to investigate the case would put to the medical witnesses the following question :—"Is it possible to ascertain whether ashes found in a furnace are derived from the combustion of an infant?" The day after receiving the above question I answered to the effect, that it was an easy matter to resolve the problem proposed. The ashes of a fœtus, on being calcined with potassa, ought to yield cyanide of potassium ; whereas the mere wood ashes, on being treated with the alkali, furnish no trace of the cyanide. This question being of some interest, I undertook a series of experiments, which will constitute the subject of the following memoir : the results of my labour, while more than sufficient to resolve the problem in question, may, perhaps, be useful some day in elucidating a question of a similar kind to that addressed, in 1840, to my honoured friend, Ollivier (d'Angers)—I think I ought first to state the case described by this experimentalist, as it will make known the present state of science on this point.

CASE OF M. OLLIVIER (D'ANGERS.)

The female L. states that she was in the sixth or seventh month of her pregnancy, when on a sudden, towards midnight, she was seized with labour-pains, and having no notion of the cause of her sufferings, she rose to satisfy a call of nature. Immediately, however, the head of a child, giving no signs of life, was expelled. She divided the umbilical cord, and the delivery became gradually complete. According to the statement of the woman L. the labour and act of parturition lasted only a quarter of an hour. After having wrapped the infant in linen, she concealed it under a mattress. Feeling convinced that her pregnancy was unsuspected, she intended to destroy the body, and contrived to burn it, so as not to leave any traces behind. After having kindled a strong fire in her room, she put the body on the burning mass, which she maintained in a continual state of ignition. She believes that about four hours were required entirely to consume the body. She was not aware that, mixed with the ashes, numerous particles of partially incinerated bones were left.

M. Freyssinaud, the judge in this case, asked the opinion of M. Ollivier (d'Angers) and Dr. Evrat, and sent to them, besides other matters, a vessel containing five killogrammes (ten pounds) of ashes, partly in a humid state. It appeared by a simple inspection, that the bony *residuary mass*, which was mixed with the ashes, was extremely brittle, being generally *almost completely calcined*. The experimentalists thought at first that these fragments could easily be separated by a sieve ; but owing to their great brittleness, it was necessary to abandon this means of separation. To avoid destroying entirely the bones remaining, the nature of which it was important properly to ascertain, it became necessary to employ delicate forceps to remove the fragments singly.

The conclusions given in the report were as follow :—

1. The bones, the fragments of which have been examined by us, evidently belong to a human fœtus.

2. After having compared several of these bones with one another, and with those of other fœtal skeletons, we think we are warranted in maintaining that the infant, of which the female L. was delivered, was a mature one.

3. Several bones of the woman L.'s child, on being compared with similar ones of other skeletons of the same age, were found to be in such proportion as to induce us to suppose that this infant was very large.—(*Annales d'Hygiène*, vol. xxvii. p. 350.)

As in the above case incineration was not persisted in to its utmost extent, the problem now before us is left considerably untouched. Not only could the fragments of bones, mixed with the ashes, be recognised, but it was likewise possible to determine that they were the bones of a fœtus, and even to ascertain its age. This would not have been the case, of course, if the calcination had reached a higher degree, and had changed the osseous fragments to such an extent as to convert them into a coarse powder. I must add, that this is the common case, for when I burnt bodies of mature infants, I obtained with the ashes fragments of bone of greater or less size, but generally of such small dimensions, that in most instances it was difficult to say to which particular bone they belonged. The question to be discussed for the present applies, therefore, only to cases in which the fragments cannot be recognised, either because the calcination has reached a high degree, or because the ashes have been triturated in such a manner as to furnish an almost homogeneous powder.

Experiment 1.—I calcined blood until it was reduced to ashes; four grammes of which, after being treated with boiling water, furnished a *solution*, which on being mixed with sulphate of iron, even when acidulated by hydrochloric acid, did not give the slightest trace of *prussian blue*. If 4 grammes of these ashes be calcined with 50 centigrammes of pure potash, and then boiled with water, the solution acidulated, filtered, and acted on by the same reagents, furnishes a perceptible quantity of prussian blue.

Experiment 2.—The above ashes calcined for two hours without an addition of potash, until incinerated as completely as possible, and treated with boiling water, produced the same effect as the foregoing. If 4 grammes of the same ash be calcined with 50 centigrammes of pure potash, and the product dissolved in water, acidulated with hydrochloric acid, and treated with sulphate of iron, a considerably less quantity of prussian blue is given than that of the foregoing experiment.

Experiment 3.—A fœtus of 7 months was burnt, the ash was of a gray colour, and contained fragments of bones of a white colour.

Examination of the Bones.—After having reduced them to powder, 5-6ths of the whole were mixed with 2 grammes of concentrated and pure sulphuric acid, a small quantity of *sulphuretted hydrogen* was soon disengaged, which could be recognised by the odour it diffused, and its action on white paper, impregnated with acetate of lead, which was turned brown. Three days after, the action on the bones by acid being ended, the mixture was boiled with distilled water for one hour; the liquid when filtered was of an acid reaction, and contained biphosphate of lime ; the precipitate thrown down by pure ammonia was white, and the liquid, after being evaporated to dryness, and mixed with charcoal, yielded phosphorus, when heated to redness.

Examination of the Gray Ash.—2·6 grammes of this ash, after being boiled with distilled water, and treated with sulphate of iron, gave no prussian blue. The same quantity of ash, on being calcined with 0·3 grammes of pure potassa, and dissolved in boiling water, gave a colourless and limpid fluid; this fluid after having been filtered and acidulated with hydrochloric acid, on the addition of a few drops of a solution of sulphate of iron, yielded a greenish blue colour, without any turbidness, and on the following day a small quantity of prussian blue was deposited. If a very small proportion of animal ash be calcined with potassa, the mass dissolved in boiling water, and then acidulated with hydrochloric acid, it frequently happens that the liquid thus obtained, on being treated with sulphate of iron, is not rendered turbid at first, but generally becomes yellowish; some hours afterwards, however, it acquires a green colour, without ceasing to be transparent; finally, it turns blue, and is opaque, throwing down after twenty or thirty hours a precipitate of cyanide of iron (prussian blue). By treating 2·6 grammes of the same gray ash with 1 gramme of pure sulphuric acid, sulphuretted hydrogen gas was disengaged; after remaining in contact for three days, the mixture was boiled with distilled water, when a liquid was obtained which reddened litmus paper, and contained biphosphate of lime: by pure ammonia phosphate of lime was thrown down.

Experiment 4.—I burnt a mature fœtus, the gray ash mixed with osseous fragments was reduced to powder, one half of this powder weighing 4·7 grammes, on being treated with the sulphate of iron, produced the same effect as the gray ash in experiment 3, except that a more copious precipitate of prussian blue was obtained. The remaining portion being treated with 2 grammes of pure sulphuric acid caused sulphuretted hydrogen gas to be disengaged; after having remained in contact for three days, the mixture treated with boiling distilled water, yielded a liquid reddening litmus paper, and containing biphosphate of lime.

Experiment 5.—The same experiment repeated with 5 grammes of gray ash, mixed with bones obtained by burning a fœtus of eight months, and treated with sulphate of iron, and sulphuretted hydrogen gas, gave exactly similar results.

Experiment 6.—I treated 40 grammes of oak-ashes with boiling water, that is to say, a quantity eight or ten times greater than the animal-ash I before experimented on. The solution was alkaline, restoring the *blue colour* to litmus paper reddened by acids; it precipitated the sulphate of iron of a green colour, and hydrochloric acid dissolved the precipitated oxide without leaving the slightest trace of prussian blue. After calcining 40 grammes of the same ash with 4 grammes of pure potassa for one hour in a *covered* crucible, and boiling the residue with distilled water, an alkaline *liquid* was obtained, which threw down the sulphate of iron with a deep green colour; but the precipitated oxides of iron being instantly dissolved by hydrochloric acid, left *behind no atom of prussian blue*. 40 grammes of the same ash mixed with 16 grammes of pure sulphuric acid gave *no trace of sulphuretted hydrogen gas*; after having been left in contact for three days, the mixture was treated for one hour with boiling water. The liquid, *instead of being of an acid reaction*, as was the case in experiments 3, 4, and 5, was alkaline, restoring the *blue* colour to litmus paper reddened by acids; and was not precipitated by pure ammonia.

Experiment 7.—The last-mentioned experiment being repeated with a similar quantity of ash, obtained from the charcoal used in the laboratory, on being treated with water, sulphate of iron and pure sulphuric acid acted like the foregoing.

Experiment 8.—I repeatedly calcined charcoal from the oak, fir, &c., with potassa, *in open crucibles*, and obtained invariably the same results.

Experiment 9.—I treated with boiling water 40 grammes of the ash of vine twigs; the solution was alkaline, and when, after being acidulated with hydrochloric acid, it was mixed with *sulphate of iron*, no prussian blue was obtained. The same quantity of ash calcined in a *porcelain crucible* for one hour, and then treated with boiling water, gave a *solution*, which being acidulated, and mixed with sulphate of iron, yielded no prussian blue. When, however, it was calcined in a *hessian crucible*, and the aqueous solution obtained by boiling was acidulated with hydrochloric acid, and mixed with *sulphate of iron*, a slight green precipitate was thrown down, very different from prussian blue, and probably formed of silicate of iron. It is important not to confound deposits of the latter kind with prussian blue, which is well characterised by its colour and other properties. 40 grammes of the same ash mixed with 16 grammes of pure concentrated sulphuric acid, gave off a small quantity of sulphuretted hydrogen gas, and being allowed to stand for three days, and then boiled with distilled water, the solution thus obtained was of a slightly acid reaction, and was slowly precipitated by ammonia.

Experiment 10.—25 grammes of rhamnus frangula (bois de bourdaine) were calcinated with potassa, and the mass left behind was boiled with distilled water. The filtered liquid, on being acidulated with hydrochloric acid, and mixed with sulphate of iron, yielded no prussian blue. 25 grammes treated with 10 grammes of pure concentrated sulphuric acid, after having been in contact for three days, was boiled with distilled water, and furnished a solution with *scarcely* a trace of an *acid reaction*, and from which, by pure ammonia, no sensible quantity of phosphate of lime could be precipitated. By treating this ash with sulphuric acid, no sulphuretted hydrogen gas was disengaged.

Experiment 11.—150 grammes of turf ashes being continued with pure potash, yielded a product,

which, treated with distilled water, acidulated by hydrochloric acid, and mixed with sulphate of iron, gave no prussian blue. The same quantity of ash mixed with 60 grammes of sulphuric acid, disengaged no perceptible quantity of sulphuretted hydrogen gas. After a contact of three days, and boiling with distilled water, the filtered liquid was found to be *highly alkaline*, and treated by carbonate of ammonia threw down no precipitate.

Experiment 12.—50 grammes of peat ashes (mottes à bruler) were calcined with potassa, and the product obtained boiled with distilled water; the solution filtered, acidulated with hydrochloric acid, and mixed with sulphate of iron, yielded no prussian blue. The same quantity of ash after being in contact for three days with 20 grammes of pure sulphuric acid, disengaged scarcely any sulphuretted hydrogen; by treating with boiling water, a *solution* was obtained of a distinctly *alkaline* reaction, which by contact with ammonia, threw down no precipitate.

Experiment 13.—150 grammes of coke ashes were calcined with potassa, and the residue boiled with distilled water; the acidulated solution mixed with sulphate of iron, yielded no prussian blue. An equal quantity of the same ash, mixed with 60 grammes of pure sulphuric acid, disengaged a considerable quantity of sulphuretted hydrogen gas; after having been allowed to stand for three days, it was boiled with water; the solution obtained was of a *highly acid* reaction, and being treated with pure (not carbonated) ammonia threw down an *abundant* precipitate.

Experiment 14.—150 grammes of coal ashes (houille, pit-coal) were calcined with potassa, and the residue boiled with distilled water for a quarter of an hour, the solution acidulated with hydrochloric acid, and treated with sulphate of iron, yielded a small quantity of prussian blue. A similar quantity of ash, decomposed by 60 grammes of pure sulphuric acid, disengaged a considerable quantity of sulphuretted hydrogen; and when, after having been allowed to stand for three days, the mass was boiled with distilled water, a solution was obtained of a highly *acid reaction*, containing a *large quantity* of phosphate of lime and sulphate of iron.

Experiment 15.—40 grammes of ash taken from a fire-place in which wood was burnt with coke, were calcined with potassa, and the residue boiled with distilled water; on adding to the *solution* thus obtained sulphate of iron, a *scarcely perceptible precipitate* was thrown down.[1] 16 grammes of pure sulphuric acid being thrown on 40 grammes of the same ash, scarcely any sulphuretted hydrogen gas was disengaged; after boiling the mixture with distilled water, the solution was found to be of an acid reaction, and phosphate of lime was precipitated by ammonia.

Experiment 16.—40 grammes of ash, taken from a fire-place, on which *wood is burnt*, but into which *rags, bones, and fragments of meat* are thrown, on being treated to redness with potassa, left behind a mass, which, after being dissolved in boiling water, acidulated with hydrochloric acid, and, treated with sulphate of iron, yielded a little prussian blue. 16 grammes of pure sulphuric acid being thrown on 40 grammes of the same ash, disengaged a small quantity of sulphuretted hydrogen; the mixture, having been allowed to stand for three days, was boiled with distilled water; a liquid was thus obtained of a slightly acid reaction, from which, by ammonia, rather a copious precipitate of phosphate of lime was thrown down.

Conclusions.

1. When the ash of a fœtus is not mixed with fragments of bones, which can at one glance be distinguished from other ashes, it may be recognised by the following characters:—*a*. If it is calcined with potassa in a porcelain crucible, either open or closed, cyanide of potassium is obtained, even though a very strong and long-continued heat be applied during the operation; on boiling the product obtained by the action of the alkali with distilled water, and treating this solution with sulphate of iron, a dirty green precipitate is thrown down (cyanide of iron and ferroso-ferric oxide); this precipitate disappears almost entirely by an addition of hydrochloric acid, which dissolves the ferroso-ferric oxide, and leaves behind the cyanide of iron (prussian blue); sometimes the quantity of the latter body is so small that it is not deposited before the expiration of twenty-four or forty-eight hours. *b*. By treating the ash of a fœtus with two-fifths of its weight of pure and concentrated sulphuric acid, sulphuretted hydrogen gas is invariably disengaged; hence white paper, impregnated with acetate of lead, being held over the vessel in which the experiment is made, becomes immediately brown or black. The ash of the fœtus being allowed to stand with sulphuric acid for three days, and then boiled with distilled water for a quarter of an hour, the solution is *invariably of an acid reaction*, strongly reddening litmus paper. *c*. This solution invariably contains biphosphate of lime, and, consequently, if treated with ammonia (not the carbonate), precipitates a considerable quantity of phosphate of lime.

2. The ash of *charcoal of the oak or fir tree*, calcined with potassa in a porcelain crucible, either open or closed, contains no cyanide of potassium, and on being treated with two-fifths of pure and concentrated sulphuric acid, disengages no sulphuretted hydrogen gas; and on allowing this mixture to stand for three days, and boiling with distilled water, the solution is *invariably of an alkaline reaction*, restoring the blue colour to paper reddened by acids; finally, by ammonia (not the carbonate) no precipitate of phosphate of lime is thrown down.

The above differences between the two sorts of ashes are so characteristic and decided, that they may be found even in a quantity similar to that employed above, which is eight or ten times greater than the ash of a fœtus. It will, therefore, be easy to distinguish these two sorts of ashes from one another. And if a mixture of ashes of the oak or fir tree with those of a fœtus are delivered for examination, the experimentalist will easily discover that it is not wood ash alone with which he has to deal.

3. The ashes of peat act like those of wood, except that, by a treatment with pure sulphuric acid, traces of sulphuretted hydrogen are disengaged.

The ash of rhamnus frangula (bourdaine) being treated with potassa, yielded no cyanide of potassium, but mixed with pure sulphuric acid a scarcely perceptible amount of biphosphate of lime was obtained, and no sulphuretted hydrogen was disengaged.

5. The ash of vine twigs acted like the foregoing, except that a few atoms of sulphuretted hydrogen were disengaged.[1]

6. The ash derived from coke gave no cyanide of potassium, but it yielded a considerable quantity of phosphate of lime, with a copious disengagement of sulphuretted hydrogen gas.

7. The ash of the oak and fir tree, mixed with ashes of coke and remnants of animal matters, acted nearly like the ashes of a fœtus, except that they furnish a great deal more prussian blue, sulphuretted hydrogen, and phosphate of lime.

8. The ash of (pit) *coal* offers the same reactions as the foregoing, except that it gives a small quantity of prussian blue.

9. The ash of *turf* gave neither cyanide of potassium nor biphosphate of lime; but it disengaged a perceptible quantity of sulphuretted hydrogen, when treated with pure sulphuric acid.

10. It follows from the above statements that the experimentalist should be extremely cautious in giving an opinion on the nature of ashes, if he could not ascertain whether the fœtus was burned with wood of either the *oak or fir tree*, or *such other kinds* as contain neither nitrogen nor sulphur, as other combustibles might have been employed, which, if not with all, yet with some of the above reagents, produce the same effects as the ashes of animal matter.—*Annales d'Hygiène Publique*, July, 1845.

[1] It clearly appears that the small quantity of prussian blue is owing to some fragments of bones, or other animal matters, which might have been thrown into the fire.

[1] The difference observed between the ash of the vine-twigs and that of the above kinds of wood may be owing to the nature of the manure employed in vine plantations. With reference to the sulphuretted hydrogen, it is evident that it will be disengaged, whenever the charcoal yielding the ash contains one or several sulphates, susceptible of being converted by the charcoal into sulphurets.

NOTICES TO CORRESPONDENTS.

☞ *Subscribers who are in arrear since Midsummer, are requested obligingly to forward their remittances. By paying in advance for the year, a saving is effected to them, and much trouble about accounts spared us. Our rule is to be paid in advance.*

W. M.—*We recommend our correspondent, who is very properly desirous of becoming a Fellow of the New College of General Practitioners, to enrol his name immediately as a Member of the National Association.*

A Constant Reader, *Dublin.—A few copies, from the commencement, of the Pharmaceutical Number remain. If our correspondent wish to complete his set up to the present period, we advise an early application.*

R. P., *Leeds.—The Pharmaceutical volume will extend to twenty-four numbers, one of which is published on the first of every month. Fifteen Numbers have been already published.*

Maritus *will find an answer to his first question in one of our Pharmaceutical Numbers already published; we are unable at the moment to indicate the precise number. An explanation of his second question would be clearly unfitted to our columns.*

A Young Surgeon and Apothecary.—*We believe all English diplomas to be recognised in the United States. Each state, however, has its own peculiar laws on the subject; and in some, considerable changes have recently taken place in medical legislation. We should, therefore, recommend our correspondent not to decide without a serious consideration of the subject, and an inquiry into the changes to which we have alluded. All sound knowledge finds a ready market in America, and a market certainly not so much overstocked as our own. Accoucheurs can never be dispensed with in any civilised country.*

A Subscriber, Nottingham.—*Many thanks for the donation. The amount received will, at the termination of a reasonable period, be announced by the committee, as one or more prizes to be competed for by the profession generally of the United Kingdom. For the present, gentlemen are requested to forward any remittance, by post-office order, to the Treasurers, W. Griffith, Esq., Lower Belgrave-street, Pimlico, and R. B. Knowles, Esq., 59, Arlington-street, Camden-town; to the Honorary Secretaries, W. B. Costello, Esq., M.D., Golden-square, and Wyke House, Brentford, and J. Foote, Esq., Tavistock-street, Covent-garden; to Mr. Baillière, the Medical Bookseller, Regent-street; Mr. Renshaw, the Medical Publisher, Strand; or to the Publisher of the* Medical Times, 49, *Essex-street, Strand.*

We have received a copy of the Montrose Standard, *in which a communication from* "our London Correspondent" *suffices to prove the extreme ignorance of the writer on a topic he has chosen very largely to dilate on—viz., medical polity.* Our London Correspondent *has evidently not read the* Medical Times *he criticises, or he would not have prosed on the timidity with which medical journals express themselves on the different phases of Sir James Graham's Bill.*

The Case of Poisoning, *sent by* Mr. Thomas, *shall be inserted in an early number. He has our thanks for his suggestion.—The uncommon medico-legal case of Mr. Hunter Lane shall appear next week.—Papers by Mr. H. W.—Clito.—Medicus.—A Constant Reader, Bath.—Inquirer.—A Friend to the* Medical Times.—*M. D. declined—Several other communications have been received, which are under consideration.*

F. B.—*Conflicting statements have been made on the use of Mesmerism as a medical agent, it is supposed to be most effective in nervous maladies, in reference to which it is said to have a very similar agency to Indian hemp, aconite, &c. We have no personal experience on the subject, but are disposed, at least till it be further investigated, not to treat the matter with any show of intolerance. F. B. must be referred to the Zoist for the further information he seeks. There are, in* vol. vi. *of the* Medical Times, *records of some medical cases by Dr. Elliotson, in which Mesmerism was the agent used.*

X. Y.—*It is our rule to let all parties, as far as we know how, have fair play. We have no*

interest in the discussion, save that of letting the best horse win.

G. B. Z.—*The College of Surgeons require no apprenticeship, and consequently no indentures. The Apothecaries' Society have no power, under their act, of dispensing with indentures. We know that, in special cases, they venture to stretch their courtesy very considerably, but the case of G. B. Z. is, we fear, beyond their power.*

C.—*The University of Edinburgh is in a worse plight than O. P. Q. paints it, if C.'s advocacy would benefit it.*

"Non tali auxilio, nec defensoribus istis
Tempus eget."

Whoever be O. P. Q., his personality has nothing to do with the question which is, "Has the system pursued by the university and its rulers, as developed in the works of its teachers, tended to do for Science all that should have been done?" C. is quite out on this question. We leave the defence, therefore, in the more prudent hands of Dr. Lewins.

We regret that an accidental circumstance has postponed until next week the continuation of Dr Clay's paper on Asphyxia, and the paper on Mesmerism by Dr. Warenne, which are in type.

THE MEDICAL TIMES.

SATURDAY, AUGUST 9, 1845.

Trembling, hoping, lingering, flying,
Oh! the pain, the bliss of dying!—POPE.

A HUNDRED respectable practitioners met during the last week, at Sheffield, to discharge, for the Provincial Medical and Surgical Association, at an important moment, the accumulated arrears of a year's business. Two days (besides a journey) did those estimable gentlemen give to public business: for forty-eight hours did they, unflaggingly for the Profession, speak, write, discuss, form committees, give reports, and eat dinners; and yet the great aggregate result suggests, as a natural query, what was the meeting for? Why was it held? What has it done? The Association's use has certainly undergone a sad ordeal in this annual meeting of 1845. Some huge want seems revealed, when the great event of a twelvemonth's history offers so little of actual doing. From the labour of so stupendous a mass, people expected a more important birth.

In the Sheffield papers and columns of our respected cotemporary, the "Provincial Medical and Surgical Journal," we find an able digest of the two days' proceedings. Let us briefly narrate the principal points.

The president-elect, Dr. C. Thompson, of Sheffield, having declined, from a medico-political difference of opinion, to fill his chair, had a substitute elected in Dr. Favell; and the last year's president and his successor delivered the short valedictory and introductory addresses suited to their respective positions. The Council's report followed, touching receipts and expenditure, increase of members, benevolent fund, medical reform, and poor-law. It was noticed that Dr. Green, who had been awarded £516 11s. 4d. for losses sustained by his connection with the Association's Journal, should be paid by five-shilling subscriptions; a committee was named to give an opinion on medical reform; thanks were voted mutually, additions made to the committee, fruitless discussions on an increase to the benevolent fund indulged in, and a case of medical practice read. So ended the first meeting of the morning.

In the evening a report, showing the Association's inefficiency as a medical board of benevolence, was read; a long proposition submitted on a new annuity fund, and a retrospective address on surgery, delivered by Mr. Teale. The evening finished with the view of a *time*-honoured "*reflector*" adapted to the speculum—an ingenious invention, no doubt.

On the second day some discussions occurred on the subscriptions for Dr. Green's repayment, a retrospective address was delivered on medicine by Dr. Charlton, and a resolution taken that that everlasting bone of contention, the Journal, should be continued another twelve months. Brief reports were read, showing that the scheme for the school of medical men's sons was not progressing satisfactorily, and that Sir James Graham's future bill should contain two or three reasonable points of medical reform. Three or four papers were read on medical subjects; as many announced as received; and, with some formal thanks and arrangements for a meeting next year at Norwich, the business ended. A dinner followed, marked by the usual loyal and amiable toasts, and so ended a great annual meeting formed of medical men travelling from all parts of England!

Now, we are not disposed to deny that the Provincial Association has done good, or that, with the management that befits it, it might not do more. Composed of worthy and respectable men, as a body, its managers are practitioners animated with the purest intentions to serve their brethren; but we venture to think that, by one false step after another, they have got their Association into that pass in which they cannot longer, without a large change, work it either efficiently, or satisfactorily, or usefully. In every aspect in which it can be viewed—under every form under which it was originated—it stands out a complete and helpless failure. As a scientific society for the promotion of high professional knowledge, it is not worth a report. As a joint-stock publishing society, it is equally imperfect and unsatisfactory. As a political organ, its power and influence have completely gone. As a medical benevolent society it has signally and lamentably failed. As the originator of a system of medical schools for the sons of medical men, it unfortunately threatens to be not less unsuccessful. These are strong sentences, but they are still but the sentences of "soberness and truth." An association, in the annual receipt of £2000, assumes credit to itself for devoting "*not less* than £220" to distressed medical men during a year when the claims have been "unusually numerous and pressing;" and for the next year it has not a farthing for eleemosynary needs, save what may be furnished by voluntary donations forwarded in *addition* to the usual annual subscription! So much for the Provincial Association as a society for the relief of its more indigent members.

Why debate on its inefficiency as a political engine? Why has the National Association reached its 5000 members, and been treated with by Government as the only association representing the Profession, but simply because the Provincial Association, at the most critical period of our history, abdicated its functions as a medico-political body, showing itself either ingloriously mute or ambiguously laconic? At this instant the Association is a political nullity. It is followed by nobody, feared by nobody, looked up to by nobody. The colleges have forgotten, and Sir James Graham has never heard of, its existence! Why is this?—why is it that an Association which should have enlisted under its banner all those who are now enrolled on the books of a society of yesterday, which should stand before Government as a great regulating power, and time-honoured representative of the Profession—why is it, in the very moment when it should be everything, that it has thus become a political nonentity? The answer is easy. The energies of the Association have been frittered away in too many objects; ends positively incompatible have been sought. It has been turned into a mercantile confederacy, subjected to all the exigencies of a trading firm—the question of profit or loss—increase of members or bankruptcy—coming into consideration on every question of professional right or sound policy. Its ruling managers, having to keep together, *quocunque modo*, a large body of members, for the sake of revenue, are compelled to place principle under the dominion of money. They have so fixed their body, that it cannot safely speak out frankly or act decisively. How can they, when, if an honest opinion were not well received, the Worcester Council would have to be gazetted as unsuccessful traders!

With regret we say it, but the necessity of duty compels us to declare, that the Sheffield annual meeting was emphatically what the Duke of Wellington called all such affairs—a farce. It was only not ridiculous, because it was lamentable. Why were 100 men dragged from their far homes and useful occupations to be told, "We are an Association for promoting Medical Reform; but we cannot express a bold and decisive opinion, or sustain with influence a respectable and effective policy! We are a joint-stock publishing society, but we must curtail the expenses of our only two publications! We have engaged ourselves to support schools for the sons of medical men, but we have nothing for the object, and voluntary subscriptions will not do! We are a Benevolent Association, in receipt of £2000 a-year, but we cannot afford to give a single £100, nay, a single farthing, during the coming year for an eleemosynary purpose! Even a debt of £500, that we unwittingly incurred as publishers and booksellers, must be raised in pittances of five shillings by subscriptions per member, or not paid at all!" These are the startling confessions of a great medical confederacy, that, with a more courageous, and straightforward, and generous management, might by this time have wielded the whole power of the Medical Profession—these the tremendous shortcomings of what should be a vast medico-political engine, all influential in the impending reorganisation of the Profession! Beyond the things told of in this sad summary—this autographic indictment—the

annual meeting's doings consisted of *nothings*—emphatically nothings—for what else to a Profession in the position of ours are votes of thanks, tenders of mutual compliments, and cheerings of loyal toasts? The amount of mutual admiration expressed was indeed edifying. The meeting seemed like the anniversary of a society founded for the promotion of mutual admiration: the extent in which this exhilarating commodity was dispensed at the meeting was much in the proportion of which its want is likely to be in other quarters.

Let us say to the respectable secretary, Dr. Streeten (who, like all connected with the Association, gives great toil and labour for small payment), and to the very able president of the Worcester Council, Dr. Hastings, that they cannot too soon resolve on an effective change. This annual meeting has demonstrated that they have too many irons in the fire, and that some of the best of them are growing cold. A great political power they may be, compatibly with making provision for their own misfortune-stricken brethren, but not compatibly with the support of a journal, which requires them to devote about a fourth of their funds—nearly £500 per annum—in payment of government duties alone. To *give away* so large a sum is monstrous; and it might well be thought on, whether the whole amount, inclusive of this waste, spent about the Journal, could not be far better employed in some other manner. A known organ to a political party, written by its chiefs, and for whose every word, act, or omission of word or act, a large Association with discordant elements is directly, and in so many words answerable, seems to us the greatest nuisance a political organisation can be cursed with. If *not* plain-spoken, decided, and fearless, it is a contemptible rag; if the contrary, it must ruin the Association. Appearing weekly, its ominous silence at a critical moment confounds and disappoints; its "shilly-shallying" ambiguity disgusts, or its premature decisiveness divides! It puts the Association in a false and perilous position, and is clearly incompatible with full deliberation or fixed action. It does not allow the society that full freedom, that perfect play of its mechanism, necessary to large and prudent action. It cuts off a hundred aids, and precludes a thousand precautions.

But it is said, without the Journal we lose members. If that be the tenure on which the Association hold its subscribers, how deservedly powerless is it as a political or professional engine? If true, there never was a medico-political union supported on so hollow a foundation. The fact would imply a strange insult to the public spirit of the members or the worth of the Association. For ourselves, we donot believe it.

It is, perhaps, as well to make what is, after all, a needless assurance, that we possess no interest in this matter but a public one. The *Provincial Journal* does the *Medical Times* no harm, but rather a service. It may excite, but cannot satisfy, a taste for journalism. It is a matter of fact that its readers invariably subscribe to other medical periodicals, and we know that our own circulation among them is as great proportionally as among other divisions of the Profession. Our anxiety is that the vast utilities of an influential Association should not lose themselves in paltry pecuniary matters below its care; that the position of governing influence and power, known to it in days of yore, should be reassumed through a more effective and simple organisation, and that concurring, or, better still, coalescing with the National Association, it should give the Profession the only circumstance now wanting to to secure it that happy and important change which the ruling managers of both societies have so earnestly at heart.

SANATORY CONDITION OF THE PEOPLE.

Our readers will recollect that, in concluding a series of analyses of the evidence laid before the Health Commission by physicians and surgeons resident in London, and conversant with its sanatory state, we promised to give early notice of any proceedings in Parliament bearing on the subject. With the exception of a few questions put from time to time in either House, little has transpired, and nothing has been done, till a few days since the Government fulfilled its pledge by bringing in a sanatory measure, which now lies on our table. It was ordered to be read a first time, but will not be proceeded with any further till early in the next session of Parliament, when, as we sincerely hope, it will meet with no opposition, though we think it admits of material improvement. It is entitled "A Bill for the Improvement of the Sewerage and Drainage of Towns and Populous Districts, and for making Provision for an ample Supply of Water, and for otherwise promoting the Health and Convenience of the Inhabitants."

The preamble of the bill sets forth that the sewerage and drainage of the towns and populous districts of the realm, and the supply of water for the domestic use of the inhabitants, and for the due cleansing of drains, are extremely defective, or utterly neglected, especially in the districts chiefly inhabited by the poorer classes, whereby excessive disease and great mortality have been occasioned; and that the general laws in force are wholly insufficient for the remedy of so great a mischief, and the like defects, for the most part, exist in the power of trustees acting under the authority of divers local acts.

As a remedy for these evils, the bill empowers one of her Majesty's principal Secretaries of State to nominate inspectors of competent skill and science, who, previously to the making of an order in Council for enforcing the provisions of the act, shall be directed to visit and report on the state of any town or district, particularly in respect to the state of the drainage thereof, the quantity and quality of the water supplied to the inhabitants, the average amount of mortality among the population, and generally on the sanatory condition of such town or district, and on any other matters or things which may be deemed necessary and proper for the purpose of enabling her Majesty to judge of the necessity and expediency of ordering the provisions of this act to be in force within any such town or district. The inspector shall also, if required, describe and mark down on a plan the boundaries of the town or district, and if the town contain more than 10,000 inhabitants, divide it into wards, of which he shall also describe and define the limits, and assign to each ward the number of *commissioners*.

These commissioners, whose duty it is, subject to the surveillance, direction, and approval of the inspector, to carry the provisions of the act into play, are to be designated "The Commissioners for Water and Sewers for ——"

The Report of the Inspectors having been submitted to her Majesty in Council, it shall be lawful for her Majesty to direct, by an order in Council, that, at or from a time named in the order, the provisions of the act shall be in full force and operation in the town or district in question.

In addition to the inspectors and commissioners of water and sewers, two other officers are created by the act—a medical officer of health, and an inspector of nuisances.

The first 110 clauses of the bill are chiefly taken up with defining and limiting the powers of the commissioners, prescribing the mode of election, the qualifications of electors, and other matters of little interest to the general reader, and of course differing little from the machinery of other bills of a similar nature. The duties and powers of inspectors are also further described.

From the succeeding clauses we learn that the commissioners are to be surveyors of highways, to have the management and control of all streets in their town or district, with power to level and pave, to create public highways, to fence footways, to make and alter sewers, remove obstructions to efficient drainage, to construct house-drains, to cause gully-holes to be trapped, and drains, privies and cesspools to be kept in good order, to cause streets to be cleansed, and dust and ashes to be removed from the houses, to abate nuisances, to form public conveniences, to provide means of watering the streets, to order houses to be whitewashed and purified, to regulate and inspect lodging-houses and slaughter-houses, to supply, or arrange for the supply of, water to districts not already supplied by water companies, including the supply of houses, public cisterns, pumps, baths, and washhouses, and for the extinction of fires.

The commissioners are provided with ample powers for effecting all these important objects, and for raising by rates the necessary funds. As far as a first, and not a careless, perusal of the act enables us to judge, the commissioners are armed with the power and means necessary for effecting the improvements so urgently called for. The machinery appears to us to be efficient, and not likely to get out of repair. A system of inspection, which hitherto has been so great a desideratum, is also supplied, and the means are provided of carrying the recommendations of the several inspectors—the inspector-in-chief (if we may give him a name), the medical officer of health, and the inspector of nuisances—into effect.

The bill also defines the width of streets to be hereafter constructed, namely, of a carriage-road *thirty* feet, of a footway *twenty* feet, but if the buildings skirting the carriage road or footway respectively shall exceed the height of thirty and twenty feet, then the width of the street shall be at least equal to the height of the houses. The act, moreover, prohibits the letting, as a dwelling, of rooms below the level of the street, unless such rooms shall be provided with areas to the extent of at least five feet long by two feet six inches wide, (together with an open fireplace furnished with a proper flue, and a window opening at least nine superficial feet in area), of which at least four and a half superficial feet shall be made to open for ventilation.

There are several other provisions which, if our space were less limited, we might point out, such as the power given to the commissioners to purchase, provide, and maintain apparatus necessary for searching for drowned persons, and for restoring suspended animation. For the details of the measure, however, we must refer our readers to the bill itself, contenting

ourselves with a few additional observations on the new officer screated by the bill, especially the medical officer of health, and one or two defects which, as we think, might and ought to be remedied.

The duty of *inspector of nuisances* consists in superintending and enforcing the due execution of all duties to be performed by the scavengers appointed under this act, and to report to the commissioners all breaches of their bye-laws and regulations, and to point out the existence of any nuisances. The inspector is also required to keep a book, in which shall be entered all complaints made by any inhabitant of the town or district of any deficiency in the supply of water, and of any infringement of the provisions of the act, and the inspector shall then inquire into the truth of such complaints, and report to the commissioners. This report, and the order of the commissioners thereon, shall be entered in the said book, which shall be open at all times to the inhabitants of the town or district, and the inspector, subject to the direction of the commissioners, is to make complaint before a justice, and take legal proceedings for the punishment of the offenders.

The *medical officer of health*, with whose functions we are most interested, is to be appointed by the commissioners, subject to the approval of the secretary of state. He is to be a legally qualified medical practitioner, of skill and experience, whose duty it shall be to inspect and report periodically on the sanitary condition of any town or district, to ascertain the existence of diseases, more especially epidemics increasing the rates of mortality, and to point out the existence of any nuisances or other local causes which are likely to originate and maintain such diseases, and injuriously affect the health of the inhabitants of such town or district, and to take cognizance of the fact of the existence of any contagious disease, and to point out the most efficacious modes for checking or preventing the spread of such diseases, and also to point out the most efficient means for the ventilation of churches, chapels, schools, registered lodging-houses, and other public edifices within the said town or district, and to perform any other duties of a like nature which may be required of him. The medical officer of health is also to be summoned by the coroner to the performance of post-mortem examinations with or without an analysis of the contents of the stomach, receiving for this duty no special fee, but being paid for the performance of all his duties as health officer, such a salary as shall be approved by the secretary of state.

We hail with great satisfaction the proposed appointment of medical officers of health, and we consider their duties as thus defined to be of the highest importance to the community. Nothing can tend more to raise the character of the profession than this association of its members with officers appointed for the discharge of duties of a public nature; and if proper care be bestowed on the selection of their officers, and they shall be really men of "skill and experience," we anticipate the happiest results from their labours.

It must be perfectly evident to any one who has the slightest experience of the working of public bodies, especially such as are elected by the rate-payers (and such are the commissioners in whom the appointment of the health officers is vested), that efficient officers can only be obtained by demanding a minimum of qualification in all candidates for office. Now we esteem this to be essential in the case of the health officer: he should not only be a properly qualified medical practitioner, but he should be specially qualified for his duties. We would venture therefore to suggest that, after a given date, no medical man should be eligible for this office who had not attended a course of lectures on hygiene, consisting of at least twenty-five lectures, a course of chemical manipulation, and a course of practical toxicology. He should also be required to produce a certificate of punctual attendance, and a testimonial of competency to perform chemical analyses. If the bill is expected to define the qualifications of officers, it is so far defective. It would also be highly desirable to hold out to these health-officers an inducement to the proper discharge of their duties, by providing that a certain proportion of the members of the new Board of Health to be formed under the provisions of the long-threatened medical bill, shall be selected from among the medical officers of health. It may further be well worthy the consideration of government, whether the science of state medicine might not be most advantageously promoted by endowments in the principal medical schools. If chairs were moderately endowed (say on the scale of the new Irish colleges) in Edinburgh and Dublin, and in the two colleges of the University of London, men would be able to devote themselves exclusively to these most important subjects, instead of being constrained, as now, to make a livelihood by the practice of a most engrossing profession, while all their time and attention ought to be given to the subjects they profess to teach. Hence it happens that men who have shown themselves possessed of all the qualifications necessary to the improvement of the science of state medicine are found to seize the earliest opportunity of quitting a pursuit by which it is utterly impossible that they should earn a subsistence.

These suggestions are incidental to the discussion of the qualifications of health officers, and are merely thrown out *en passant*. To return to the bill. As far as the provisions for street-cleansing, drainage, and supplies of water are concerned, its provisions appear to us wise and comprehensive; but we think that the bill should go somewhat further. With the exception of some provisions incidental to the disallowance of underground habitations, and the extension of the duties of the medical officer of health to the pointing out of the most efficient means of the ventilation of churches, chapels, &c. (see cap. 175), the subject of ventilation is altogether overlooked. We think this omission has arisen from a difficulty which has been felt in drawing the bill in selecting any plan of ventilation from the many which have been recommended. We are ourselves far from wishing the government to select any particular plan, as the one to be enforced in all cases in which ventilation may be proved to be defective, but we are strongly of opinion that something might be done. The New Building Act requires that every room intended to be occupied as a bed-room should have a chimney in it, and the same provision is made in the present bill in the case of rooms underground. Now, why should not this provision be extended to all rooms whatsoever, whether occupied as day rooms or as sleeping apartments? It might at first sight appear unnecessary to insist on this, as few such rooms are built without chimneys. This is quite true, and yet if a man will take the trouble of visiting a few of the shops and workshops of London, he will find that the chimneys are either altogether closed, and the escape of foul air rendered impossible, or partially closed for the reception of the flue of a stove, by which the escape of foul air is reduced to a minimum. We would, therefore, suggest that a clause should be inserted in the bill rendering an open chimney a *sine quâ non* in all rooms whatever, and preventing the use of stoves, unless they are provided with distinct and separate flues. This would do much for ventilation; but we must go still further, if we would prevent the present baneful system of aerial poisoning. Space is the most efficient means of insuring a due supply of air. Let it therefore be enacted, that to employ men in day-rooms, or cause them to sleep in bed-rooms, containing for each person less than 500 cubic feet of air, shall be an indictable and finable offence. A minimum quantity of air, and one exit at least for foul air, is the least that ought to be done to guard our labouring classes against the present reckless system which makes so many of them the victims of consumption. Perhaps it might be possible to infringe still further the so-called rights of property, by requiring that in all places where gas is used, provision should be made for carrying off the products of combustion. As these provisions, especially that which prescribes a minimum of space, might be attended in certain instances by serious inconvenience to the owners of narrow premises not admitting of enlargement, it might be enacted that, on adopting any system of ventilation certified as efficient by the health officer, a smaller space might be allowed to each man. These are the chief provisions which we would suggest with a view of ensuring efficient ventilation, and we believe these, or others at least as effectual, to be to the full as necessary as sewerage and supplies of water. The bill contains no provision for the consumption of smoke, which, as it seems to profess to be a comprehensive sanitory measure, it should do; nor does it contain any clause preventing the pollution of our streams of water by the truly barbarous and wasteful system of pouring into them the contents of the common sewers. Surely it might have been rendered incumbent on the commissioners to guard against this wasteful and unnecessary and uncivilised practice. If the practice were forbidden, other means of disposing of the valuable refuse of towns would be discovered. There is abundant evidence in the Report of the Health Commission to show that the more solid contents of the sewers may be safely deposited, and the liquid manure be applied with great advantage and profit to the land. Why such a provision was not inserted in the bill, we are at a loss to conceive. We have one more objection to the bill, and that is, that it does not extend to the metropolis. Why should the capital be robbed of the advantage which is to be conferred upon the rest of England and Wales? Are there too many conflicting interests? In such a matter all these should be reconciled. Does the government fear the opposition of parties interested in existing abuses? Let it boldly defy their selfishness. We do sincerely trust that no idle apprehension of the trouble of reconciling conflicting interests, no undue regard to those rights of property which have been so clearly proved to be fearful wrongs to the poor, will prevent the government from extending their measure to the metropolis. They are strong enough to carry what they esteem useful measures against the open opposition of a large proportion of the intelligent people of this country; we trust that they will not flinch before the anticipated displeasure of landlords, shopkeepers, and manufacturers. They have assumed, and we think not unjustly, that they know better what ought to be done for Ireland than a million and a quarter of petitioners, and they will scarcely be consistent if they do not turn a deaf ear and a resolute front to those who in ignorance or selfishness may oppose a truly comprehensive sanitary measure, comprehensive alike in its provisions and its boundaries. It should not stop short till it embraces the whole country

from one end to the other, nor should we leave untouched a *single cause* of unnecessary sickness and premature death. The government itself has, perhaps, formed too low an estimate of the importance of the work on which it has entered. We think, and we are sure that we do not stand alone in our opinion, that a truly comprehensive measure of sanitary reform is the most urgent and the most important subject that can occupy the attention of Parliament.

HEALTH OF THE COUNTRY.

The registrar-general has just made public a quarterly report, abounding in interest. The registrar of Charlton gives this curious account of the medical attendance of his district:—

"Thinking it desirable to know the proportion of the inhabitants who avail themselves of medical assistance in time of severe illness, I have for some years past kept a private record of the attendants in cases of fatal disease, an analysis of which gives the following result:—

"Out of 1000 cases of fatal illness recorded, there were—

"Under the care of regular medical practitioners as private patients	585
As dispensary, infirmary, and hospital patients	199
Prescribed for by druggists	117
Had no medical assistance whatever during the last illness	99

From this it appears that in this district, which contains a *smaller* proportion of the very poor than most others, nearly one quarter (226 out of 1000) are not attended by authorised practitioners even in their last illness, and many of the rest are so attended for a very short time only preceding death. There is no doubt that the proportion of those who do not obtain regular medical assistance in less severe forms of disease is very much larger. The absence of proper medical attendance, in a large proportion of cases, renders it exceedingly difficult to procure correct information of the cause of death —impossible, indeed, without great care and labour, and the employment of medical knowledge."

A statement of this kind, while showing how serviceable to the interests of the profession may be a careful and thoughtful system of registration, and therefore how much to be encouraged, offers a striking picture of the need that exists that the medical attendance which superabounds in this country should be made more available than it is—through causes easily removed—to the exigencies of the public. The mortality of the spring quarter has, after all, been less than the average. Small-pox has, however, committed fearful ravages, from the apathy of the poor to the advantages of vaccination. In the only case of death recorded after vaccination, the operation had been performed by a midwife! One hundred and four women also died from childbirth in the metropolis within three months! The weekly deaths in the metropolis fell progressively in the quarter from 884 to 756 as the temperature rose.

BOOKS RECEIVED.

Microscopic Illustrations of Living Objects. Third Edition. By ANDREW PRITCHARD, M.R.I., &c. London: Whittaker and Co.

The contents of this work convey its best recommendation. Of ten chapters two are given to a record of microscopic improvements, and explanation of microscopic terms; three to very full descriptions of a gnat, dung-fly, and a species of British hydrophilus; in two others, Dr. Goring gives us some practical remarks on the use of microscopes for viewing and drawing aquatic larvæ, and on the best possible way of constructing the stand, or mounting of microscopes; and in the other three we find extremely valuable descriptions of the achromatic microscope, and of Dr. Goring's operative aplanatic engiscope, with the best mode of using both. An appendix is added, containing Mr. Talbot's two papers on the Optical Phenomena of Crystals.

This short summary of the book's contents will suffice, without any commendation on our part, to those who follow microscopic studies, and know the claims to confidence Mr. Pritchard's long experience give him on all subjects appertaining to his favourite science.

Surgical and Practical Observations on the Diseases of the Human Foot, with Instructions for their Treatment. By JOHN EISENBERG. London: Henry Renshaw.

This elegant quarto, ornamented with superb paper and exquisite type, intimates that chiropedia is not the least profitable part of "pure" surgery. The book, however, is out of our way. Mr. Eisenberg has so many opportunities of submitting to the public by newspaper advertisement testimonials of his high professional merits, that the loss of ours on the present occasion will probably no more pain than surprise him. The work is, however, made professional by its dedication, by permission, to the author's friend, Dr. M. Hall.

Memoirs of Lady Hester Stanhope. 3 vols. Colburn.

No woman who can read should omit the perusal of these volumes; they show the energy of which a woman's nature is capable, and the impotent result of its misdirection. Had Lady Hester devoted her strange powers to those ends for which her sex was formed, her physician would have recorded, from her lips, an example to be emulated, not one to be avoided. It is lamentable to behold power wasted, taking its channel through a desert which it cannot fertilize, and which at last will choke it up. Not to any principles in nature is the happiness of the world on earth more debtor than to the soothing, gentle, and *homely* disposition of woman.

Lady Hester, with more than the common energy of her sex, wanted the practical observation and judgment of the man she *aped*. Even *her* abilities, removed from their native channel, became impotent of good. In truth, this moral—the vain consequence of power unduly exercised—is nowhere to be found more thoroughly set forth than in these memoirs of her life, related by herself in conversations with her physician. We recommend the book to be read wherever there are women. In other respects, it is worth perusal, containing an immense fund of interesting anecdotes relating to the great people of the last and passing generation.

The Oxford and Cambridge Review. July and August, 1845.

The first number of this Review contains promise of a flourishing succession. The "Policy of the New Generation" is an apology for the Young England party. It is beyond our province to say more of it than that it is well written; that praise may be extended to nearly all the others, their interest varying only according to the interest of their topics. The August number is still richer in good materials. The article on Lord Grey, by Mr. Smythe, M.P., is particularly clever. There is another thoughtful article by Lord John Manners, which is worth perusal.

Douglas Jerrold's Shilling Magazine. August.

"The History of St. Giles and St. James" (resumed) is the commencing article of this number. Mr. Jerrold continues to lay about him his powerful and keen satire: as ever, he is the sarcastic and cruel advocate of humanity. He here exposes clearly that horrible vice in nature which associates the ideas of poverty with crime.

The present chapters are, however, especially valuable from their severity—well merited, upon one of the greatest pests of justice—the thorough-paced Old Bailey barrister. Mr. Montecute Crawley is an admirable specimen of the genus; the portraiture is to the life, and medical men who have had to give evidence to such persons may well wish that some of those of whom Mr. Crawley is the type should know how well they are described, and by a covering of decency endeavour to escape the odium of the Pecksniffs, the Crawleys, &c.

The other contributions of this month are moderate, with the exception of the "Travels in Barbaraland" and "The Hedgehog Letters," which are both particularly good.

DEATH OF DR. MALE, OF BIRMINGHAM.

"Pallida mors æquo pulsat pede pauperum tabernas Regumque turres."

It is with much regret that we record the death of Dr. Male, of Birmingham, one of the most distinguished and esteemed physicians of the present day. The event, or rather the catastrophe, occurred on the morning of Saturday, July 26th, and it would have had from us an earlier notice, but that the probability of a coroner's inquest induced us to withhold our communication until we had gleaned sufficient information to be trustworthy or useful.

It appears that Dr. Male had for some time prior to his decease been the subject of severe rheumatic pains, chiefly affecting the lumbar region and the hips, for which he had tried, but unavailingly, a variety of remedies; at last it occurred to him, on reading a work recently published by Dr. Fleming on Aconite, to make trial of that drug. The circumstances will be best given in the words of Mr. Russell, as elicited at the coroner's inquest, holden by Dr. Birt Davies, on Tuesday, July 29th. "Mr. Russell, surgeon, of Newhall-street, was next sworn, and said,—I have known the deceased for a number of years. He has complained to me occasionally, for six weeks or two months past, of pains in the back and loins. On Thurday morning (July 24th), about half-past nine, his son came for me, and on going to his father's house, I found the deceased in bed. His extremities were cold; the general surface of the skin cold and clammy; the pulse 130, feeble; cramps and pains in the legs, and spasmodic pains in the stomach. He said his head was confused. He told me, that not experiencing relief from medicines in ordinary use, he had been taking tincture of aconite. He then asked me if I had ever given the medicine, and I said no. I then asked him what doses he had taken, and he replied, on the preceding Sunday five drops two or three times a-day. I cannot be positive whether he said twice or thrice, but I believe he said two or three times a-day, and had increased it to six, eight, and ten drops. One dose of ten drops only had been taken on the previous night. He had also been suffering from diarrhœa for a few days, and he had taken ten drops of solution of opium early that morning for it. I inquired where he had got his notion from relative to aconite? He said he had been reading a book now circulating through our societies, treating upon the advantages of aconite in similar pains. He expressed his conviction that he should die, that the medicine was too powerful for him; but he also expressed his most earnest desire that he might recover, as his life was of the utmost importance to his children at this time. I cheered him as much as I could, reminding him of his former depression when ill, and that I thought he had nervous power sufficient to wear out the effects of the medicine he had taken. I gave him mild aperients to overcome the poison, with camphor and ammonia. His son-in-law, Mr. Amphlett, saw him along with me in the evening, and we left him somewhat relieved. On Friday we again met, and towards evening with Dr. James Johnstone, as we found him more sunk. Dr. Johnstone agreed with us in our treatment. Late that evening I found him in a dying state. He was in a torpid condition, from which, however, he could easily be roused, and then his intellect was clear. He had no paralysis; he was perfectly composed, and died about ten o'clock on Saturday morning. Twenty hours after death I made a post-mortem examination. The body, with the slightest possible exception, was in a healthy state. The blood was unusually fluid." The jury then returned a verdict of "Accidental death from an overdose of aconite, taken medicinally by the deceased."

This case presents many features of toxicological interest. Examples of poisoning by aconite are happily very rare in the human subject, but one of the most evident and instructive of them is that which we have now the painful duty of recording. That Dr. Male died from the effects of this drug there can be no manner of doubt, and yet we should be inclined, *à priori*, to say that the doses taken were only very moderate. Dr. Thomson says that the tincture of aconite, made by digesting one part of the leaves in six parts of alcohol, "may be given in doses of from m. v to m. x, gradually increased to m. xl." In the case before us, ten drops was th

maximum dose, and was taken only once. It is probable, however, as suggested by Mr. Russell, that the poisonous action was an *accumulative* one, and that the previous doses of five drops twice or thrice daily, for two or three days, had prepared the nervous system to suffer from the impression of a larger quantity of the drug. Pereira says, that the fiftieth part of a grain of aconitina has endangered life when taken medicinally (*Elements of Materia Medica*, 1842, ii. 1811), and Christison killed a rabbit in twelve minutes by introducing the tenth of a grain of muriate of aconitina into its cellular tissue (*Treatise on Poisons*, 4th edit. p. 870). Dr. Fleming mentions a case in which two grains of an alcoholic extract of the root produced alarming effects, and another in which four grains proved fatal. These are some justification of Dr. Christison's emphatic remark, that the active ingredient of this herb is "probably the most subtle of all known poisons." But the quantity which killed Dr. Male is certainly the smallest poisonous dose hitherto recorded. At the very most, he took only eighty drops of the tincture (it is likely that he took less), and these in ten doses, during a period of four days! It is reasonable, however, to think that Dr. Male's age (sixty-six years) will account for his not bearing a dose which a younger man might have taken with impunity. But, at least, we learn from this melancholy occurrence two important facts in reference to the medicinal use of aconite:—1st, That it is a remedy of very uncertain effects; for whilst Dr. Christison has given "six grains of a carefully prepared alcoholic extract (the same of which thirty grains killed a rabbit in little more than two hours) to a female suffering from rheumatism, without being able to observe any effect whatsoever," we find a comparatively infinitesimal dose producing death in a short time, and in spite of all means used to avert it; and 2nd, That we should especially regard the age and strength of the patient to whom we administer it, and, above all things, guard against the chances of its accumulative influence.

Monkshood has hitherto been classed amongst the narcotic-acrid poisons. The following exquisite description by Nicander of the poisonous operation of hemlock has been considered to apply also to that of aconite:—

> "Tu quoque signa malæ jam contemplare cicutæ:
> Hæc primum tentat caput, et caligine densa
> Involvit mentes: oculi vertuntur in orbem,
> Genua labant; quod si cupit ocius ire, caducum
> Sustentant palmæ corpus; faucesque premuntur
> Obsessæ, et colli tenuis præcluditur isthmus:
> Externi frigent artus."

This detail of symptoms, as applied to the fatal action of aconite, serves in part, but not altogether; it fails in everything that identifies this drug with the narcotico-acrid class. It should rather be considered a *direct sedative*, and, as Dr. Fleming has lately suggested, to owe any evidence of narcotic action to a state of more or less complete asphyxia, caused by its depressing effects upon the nerves supplying the voluntary muscles. Its acridity is perhaps less questionable. Dr. Fleming, who disbelieves in this property, and denies that "purging is ever produced in any genuine case of poisoning with monkshood," contends that nausea, vomiting, and epigastric pain, may be dependent "merely on the same local nervous impression which is produced on the organs of taste" (*Christison Op. cit.* p. 872). This nervous depression is of course derived from the action of some irritant body. *Irritants* and *acrids*, toxicologically speaking, differ only in degree, and therefore run into one another, and to say that vomiting and pain in the stomach are not evidences of acrid poisoning, because they are merely repetitions of nervous impression produced upon the organs of taste, seems to us very much like talking nonsense. Any local acrid influence which is not directly *chemical* (and perhaps this applies exclusively to *mineral* substances) is due to a primary action upon the nerves of the affected part. Circulation is altered secondarily, and then comes an altered secretion, or an effusion, as the case may be. Every part of monkshood possesses a hot, biting taste, followed by a tingling of the tongue, and then partial numbness. Surely this is proof enough of *acridity*; and when such manifestation occurs in the bowels, the usual and natural consequences are vomiting and purging; and these things of course arise merely from the same local nervous impression which affected the organs of taste. How could vital organs be roused to any degree of activity without their nervous tissue being the direct medium of the functional change? The best proof, however, that we can have of aconite being an *irritant* (we will waive the *acrid* if it be desired) to the stomach and bowels, is in the fact that, in Dr. Male's case, both vomiting and purging resulted from its use, notwithstanding that its quantity was singularly small. The two other points deserving of notice are, the slow decline of strength and life, forty-eight hours intervening between the occurrence of the severe symptoms and death, and the absence of all morbid appearances except the characteristic and complete fluidity of the blood.

Dr. Male was the son of the late James Male, Esq., of Belle Vue, near Birmingham. He received his preliminary education at Eton College, where he acquired some distinction in the classics and belles lettres. His medical studies were for the most part prosecuted in Edinburgh, from the university of which place he obtained his degree. He settled in Birmingham, as a physician, in 1802, and was shortly appointed one of the medical officers of the General Dispensary, which institution he continued to serve with much fidelity and usefulness for seven years. In 1805, the resignation of Dr. Carmichael caused a vacancy in the General Hospital, and Dr. Male was fortunate enough to become his successor. To this institution the subject of our biography was an honour and an ornament for thirty-six years: it is not too much to say of him, that for that lengthened period he was unvaryingly distinguished for the kindest sympathy and the profoundest skill, towards the several objects of his professional care. To his private patients, which were both numerous and of the highest respectability, he was endeared not only by the success of his treatment, but by the soundness and integrity of his principles. He was a man of most undeviating honour and rectitude, faithful to his friends, and of unyielding firmness in whatever he believed to involve matters of truth or of duty. He was a sincere upholder of professional dignity, courtesy, candour, and kindness. Perhaps the best proof of the estimation in which he was held by the profession of Birmingham, will be found in a remark made to the writer of this article by a fellow-physician, who is too just to pay an unmerited compliment, and too generous to withhold a deserved one—the observation came with peculiar emphasis, for it was offered over a grave—"Dr. Male, Sir, was a man to whom I invariably took my hat off." That sentence, coming from a source whose uprightness none can better appreciate than ourselves, will convey a far higher tribute to the memory of the lamented individual, than any praise which it is in our power to offer.

As an author, Dr. Male enjoyed a distinguished reputation. He was the father of English medical jurisprudence. The first work upon this subject in our language, was Dr. Samuel Farr's "Elements of Medical Jurisprudence," published in 1788. This, however, was little more than an abridgment of the "Elementa" of Fazelius, and although medico-legal questions were subsequently discussed in the writings of Mead, Monro, Denman, Percival, and John Hunter, and Dr. William Hunter published an able essay "On the Uncertainty of the Signs of Murder in the case of Bastard Children," yet the first *original* work in English on medical jurisprudence, was Dr. Male's "Epitome of Juridical or Forensic Medicine." This appeared in 1816, was dedicated to Sir Samuel Romilly, and consisted of two hundred pages. It displayed an unusual amount of shrewd observation, clear reasoning, and comprehensive research. It shortly passed through a second edition, and was reprinted by Dr. Cooper in America, in 1819, along with the treatises of Farr and Haslam. Although various impediments, professional and other, prevented Dr. Male from bringing it in later years up to a later science, his work is still quoted as being upon certain subjects amongst the most exact and accurate of any extant.

It is singular that Birmingham should be able to boast, in the person of the late Dr. Male, of the first original writer on English medical jurisprudence, and in the person of the late Dr. Darwall, of the most ample annotator of the greatest work upon the subject in our language and out of our country—viz., the stupendous work of Beck, in America; and the coincidence is not more remarkable than mournful, that the distinguished individual whose memoir we now close, should have been one of our first writers on indigenous poisons, and finally a victim of the deadliest of them.

THE UNIVERSITY OF EDINBURGH AS A MEDICAL SCHOOL IN 1845

By Robert Lewins, M.D., &c. &c.

(Continued from page 338.)

[Having given our correspondent O. P. Q. an opportunity of explaining the grounds of his depreciatory estimate of the Edinburgh university, on the ground of our personal knowledge of his good faith and full acquaintance with the subject, it gives us no small pleasure to be the medium of publishing opposing observations from a gentleman of certainly not less integrity or information, and whose opinions are entitled to the highest consideration from his peculiar personal knowledge of the constitution of Scottish college life, and of the entire polity of the university of Edinburgh in particular.—Ed.]

(To the Editor of the Medical Times.)

Next in point of seniority to Dr. Graham stands Dr. Alison, as an Edinburgh medical professor. For upwards of twenty years the colleague and successor of Dr. Duncan, Dr. Alison lectured on physiology with great credit to himself and advantage to the students of the medical school of the northern metropolis. On the resignation of the late Dr. Home, in 1842, Dr. Alison was, at his own request, transferred to the chair of the practice of medicine—one more congenial to his own disposition, and for which he had been a candidate many years before, on the death of his uncle, the late celebrated Gregory. Dr. Alison is, universally, allowed to have proved himself a faithful and efficient teacher. He stands, deservedly, high in the estimation not only of students, but of all competent judges of professorial merit; his name is known and respected in Germany, in France and Italy, and in the capital, if not in the provinces, of the Russian dominions. Dr. Alison's works on physiology and pathology entitle him to a conspicuous place as a medical writer. As a benevolent physician he is adored, I had almost said, by the poor of Edinburgh. As a philanthropist he is known far beyond the boundaries of Scotland—it may safely be asserted beyond the wide limits of England.

Dr. Christison stands *fourth* in order on the list of the medical faculty of the university of Edinburgh. As a student of medicine, and a junior graduate, he established for himself a name amongst the scientific men of the age, to which he owed the first professorship he held. The talents and acquirements displayed by Dr. Christison, whilst yet a young man, were duly appreciated by those who, at the time, dispensed the royal patronage. When Dr. Duncan resigned the chair of medical jurisprudence (a *regius* one), Dr. Christison was appointed, and he filled it with great *éclat*. His matchless work on poisons, the very best on the subject in any language, has stamped him as a man of first-rate talent, and procured for him more than European fame—whilst, and wherever, science is cultivated—and, so long as it is considered an object worthy of the laws of enlightened nations to exculpate the innocent and to consign the guilty to punishment, Christison's admirable production on Medical Jurisprudence will remain an imperishable monument of his profound knowledge as a medical jurist, and of his pre-eminent talent as a writer on forensic medicine. In 1832, on the death of Dr. Duncan, the last professor of materia medica, Dr. Christison became a candidate for that chair. His opponents were—Dr. Maclagan, who had meritoriously exerted himself in improving the system of general education in Scotland, and in rendering the curriculum of the Edinburgh College of Surgeons the excellent one which it now is, and Dr. John Argyle Robertson, who had lectured successfully for several years on materia medica. Dr. Christison,

however, to the honour of the town council (the patrons of the chair) carried his election by a large majority. As a professor of materia medica he has gained additional reputation. It may be fairly, and on the present occasion particularly, stated that, as a teacher of materia medica, Dr. Christison is equalled by few, surpassed by no one in Europe. His Dispensatory, or Commentary on the Pharmacopœias of Great Britain, is a work of extraordinary merit, and supports the name he acquired by his earlier publication on poisons—whilst Dr. Christison's valuable work on Granular Diseases of the Kidneys affords conclusive evidence of his skill as a practical physician and his acumen as a professor of clinical medicine. It is not too much to aver that no individual physician has recently more effectually supported the medical scientific reputation of our country than the professor of materia medica in the university of Edinburgh; and I repeat, that nowhere is that important department of medical science better, if so well, taught as within the walls of the Scotch metropolitan university.

Sir George Ballingall's merits, as a professor, fall next to be considered. He succeeded to the chair of military surgery in 1823. Dr. Maclagan, who had served in the army with great credit to himself, was, at the period referred to, a candidate for the chair under consideration. Sir George Ballingall had been assistant surgeon in the regiment commanded by his late Royal Highness the Duke of Kent, and was, I believe, favourably known to some of his illustrious relatives. The candidates were both men of ability. It is very probable that the former was supported by the Whig, the latter by the Tory influence of Edinburgh, and probably of another place. Be that as it may, Sir George Ballingall was the successful competitor. During his incumbency the class became one of importance. Sir George Ballingall's lectures have been numerously attended, and amongst his auditors are frequently to be seen medical officers of standing in the service, some of whom—it is consistent with my knowledge—have a high opinion of Sir George Ballingall's talents as a teacher and a military surgeon. His lectures evince ample acquaintance with the literature of his peculiar department, whilst his style of lecturing is adapted to convey practical information, and it is well known that many of his pupils have distinguished themselves as medical officers in the British and Indian army. As a writer the Edinburgh professor of military surgery is favourably known by his Practical Observations on Fevers, Dysentery, and Liver Complaints, and by his work on Military Surgery, one which it is imperative on all young medical officers to study.

Dr. Traill is next in seniority as a medical professor in the university of Edinburgh. He was appointed to the chair of medical jurisprudence (also one in the gift of the crown) in 1832. In the appointment of Dr. Traill we have an example of the inaccuracy of the writer's insinuation conveyed by the query, "Whether it was or was not a fact, that family arrangements, aided by local influence, had not acted so as to exclude all talent, however elevated?"—*Medical Times*, July 19.

When nominated to his professorship, Dr. Traill was a physician in Liverpool, without local influence in Edinburgh, whilst the other candidates, Dr. Maclagan, the late Drs. Mackintosh, Fletcher, and James Gregory,* were possessed, collectively at least, of local influence, which, if local influence produced the effect insinuated by the author of the paper which has occasioned these remarks, would have been overwhelming. And it is a fact, I believe, that Dr. Maclagan was backed by the Whig Solicitor-General of the day, if not by the Lord Advocate, with a degree of party zeal somewhat indecent; nevertheless the *stranger* candidate was preferred. Political interest was, no doubt, in active operation (and a person of no less importance than Lord Brougham was said to interest himself in Dr. Traill's behalf), as it always will be on such occasions. But, contrary to the conjecture of the writer, whose sentiments on the condition of the university of Edinburgh in 1845 I hope to refute, local influence *was not* effectually exercised in favour of the Edinburgh men who were candidates for the chair of medical jurisprudence when last vacant.

London, July 30, 1845.

(To be continued.)

* Drs. Mackintosh, Fletcher, and Gregory were men of superior talents and great professional industry; by their premature death, Science lost three ardent votaries. As the intimate friend of the two former, on me devolved, alas! within the space of one short year, the painful duty of recording the merits of both. (See biographical notice of Dr. Mackintosh in the "British and Foreign Medical Review," 1838, and Dr. Fletcher's posthumous work on "Physiology, edited by Robert Lewins, M.D.," &c.) Dr. Mackintosh fell a victim to the practice of his profession, having caught typhus fever, in the discharge of its duties, of which he died. Too intense application to study sent the amiable and accomplished Fletcher to an early grave. Dr. James Gregory, a young physician of great promise, died of typhus contracted in the wards of the Royal Infirmary. It is truly heart-rending to reflect on the number of excellent members of our profession who have been cut off in the bloom of youth and in the prime of manhood by this direful disease.

GREAT MUSEUM AND LIBRARY OF PATHOLOGY, AND PATHOLOGICAL ANATOMY, FORMED OF MODELS IN RELIEF.

By DR. FELIX THIBERT.

The arrival in London of this extremely beautiful museum is to pathological collectors an event of considerable importance, and to which we beg leave to call the particular attention of the readers of the *Medical Times*. It has arrived opportunely at a moment when a question of great difficulty has arisen, namely—what is to be done with the present pathological museums? The profession generally, and especially those best acquainted with the subject, are now quite convinced that the present pathological collections have ceased to be of benefit to the student, to the practitioner, and to the lecturer; that the method of preserving morbid specimens in alcohol or other preserving liquors has been a failure, or very nearly so; that besides being all but useless in itself, the scheme is seriously expensive to those who require the use of such preparations; that as regards mere pathology, or the representation of the external appearance of disease, alcohol, &c. is wholly inapplicable; that models in wax, besides their great cost, are open to numerous objections—but too well known to those accustomed to their preservation—we shall in a future notice advert to; and that representations by coloured engravings or drawings, however beautifully executed, leave but vague impressions on the mind, soon obliterated, and wholly useless to the student.

The arrival of Dr. Thibert's museum in this country will go far to propose a remedy for, at least, some of the difficulties just stated, and promises to benefit humanity to an extent which those who have not seen the collection could scarcely credit. In this view, therefore, even without any reference to the benefits it will confer on science, the museum of this distinguished foreigner is worthy of the attention, not merely of medical men, but of heads of colleges, directors of public boards, infirmaries, dispensaries, &c.; and of the general Government itself, which in founding educational institutions in Ireland and elsewhere, ought, and will, no doubt, attend to the means for instruction with which such buildings should be furnished.

But before saying another word in respect to Dr. Thibert's museum, we strongly and earnestly recommend to the medical men of the metropolis and its vicinity, and to all interested in medical education, to visit the collection, which they will find open for inspection at 29, Bridge House-place, Newington Causeway, on Mondays, Wednesdays, and Fridays, from 11, a.m. till 4, p.m.

Our readers desirous to try further the value of our recommendation, may consult the official report of the Institute of France, of the Royal Academy of Medicine, and other official bodies, in favour of M. Thibert's discovery, as given in our advertising columns.

SWALLOWING FOREIGN BODIES.—Dr. Brookes describes two cases, in one of which a black pin, and in the other a halfpenny, was swallowed, and remained sticking in the œsophagus. In each instance the foreign body could readily be distinguished in the tube, where its presence was productive of great distress; the doctor's practice, however, was at first restricted to the exhibition of an emetic, and he did not have recourse to the probang until the emetic had proved useless. Immediate relief followed the dislodgement of the foreign bodies, which were afterwards found in the stools. We trust the experience thus gained by Dr. Brookes will induce him in future not to trust to emetics, when the foreign body is within reach of a probang.

GOSSIP.

APOTHECARIES' HALL.—Gentlemen admitted Licentiates on Thursday, August 1, 1845:—Henry Bencraft, Emanuel Peter Downs, Alexander Henry, George William Bagg, Giles Andrews, George McHenry.

THE NEW ISINGLASS PLASTERS.—The instances that have come under our notice where Mr. Macord's transparent plasters have been used, authorise us to say with Mr. Aston Key, that their qualities of adhesion and resistance to the solvent power of embrocations, give them strong claims to preference above the ordinary plasters. We may add, that their property of not irritating the edges of wounds, and their extreme cleanliness, particularly attracted our attention.

THE NATIONAL ASSOCIATION AND THE SOCIETY OF APOTHECARIES.—On Wednesday, the 23rd of July, the annual dinner of the Apothecaries' Society took place at the West India Dock Tavern, Blackwall. We observed present the principal members of the Worshipful Society, and of the Committee of the National Association. The Worshipful Master, K. Wallace, Esq., presided. After the usual loyal toasts, "The College of Physicians" was given, and Dr. Turner returned thanks. The Chairman then, in an eloquent and effective address, proposed the "National Association of General Practitioners," coupling it with the name of its venerable president, and eulogising strongly the efforts made by the Committee for the improvement of the medical profession. Mr. Bird briefly responded. After the expression of his acknowledgments, he insisted strongly that the policy pursued by the Association was directed to the general good of the *whole* profession, to whose learning and high standing, as a whole, all the labours of the Association, to his own knowledge, tended. Without detracting from the merits of older institutions, the new body sought to work in the same vineyard for the common good, not in opposition, but in concurrence with the other labourers. Mr. Ancell was then called upon, and in a lucid address described the advantages which would inevitably result from the great mass of the profession being admitted to participate more extensively in their own corporate government, and eloquently dilated on the advantages to medical science that would arise from the more fervid competition created by the stimulus of a new incorporation. The evening was spent in great hilarity, and the meeting dispersed highly gratified at the hospitality of the Worshipful Society, and the interest evinced in favour of the National Association.

GIESSEN DIPLOMAS.—Dr. Balser, the Dean of the Faculty of the University of Giessen, has written in bad French to the editor of the "Annales de Thérapeutique Medicale et Chirurgicale" of Paris, in reference to an article reprinted in that journal from the *Medical Times*. Dr. Balser talks sneeringly of "un homme Bond," and says that the "connexion" of that individual, and his "disgraceful advertisements" with the University, is an incorrect supposition: the University have taken steps, he adds, to provide against the further *machinations* of "un homme Bond." The only circumstance we have to add to this disgraceful affair is, that Mr. White, the respectable chemist in Cornhill, has written to us to say, that after the *eclaircissement* published in our journal, he has declined to allow his house to be further used as the receiving-house for the letters of Mr. Bond, alias Dr. Rowland Mackenzie.

No. 306. SUMMARY. Aug. 16.

LECTURES ON DISEASES OF THE HEART.

By D. J. CORRIGAN, M.D., Physician to the Whitworth, Hardwick, and Richmond Hospital, Lecturer in the Dublin School of Medicine, &c.

I have next to direct your attention to another functional disorder of the heart, arising in persons who have led dissolute, intemperate lives. In such persons the complaint commences with palpitations, which are excessively troublesome, and annoy the patient to such an extent as to induce a fear that organic disease of the heart may be present, and which may prove quickly fatal. The action of the heart is violently strong and tumultuous, and is often accompanied with pain shooting down the left arm as far as the elbow: these palpitations are much increased when he walks or takes exercise, if at all of a violent nature. In this state he is miserable, dreading nothing so much as instantaneous death at some period (of course) unforeseen by him; yet, with all these complaints, when you examine the heart you find its sounds natural. The tongue, in this disease, presents an appearance which you could not, *à priori*, conjecture; on examination, its sides, tip, and dorsum present a red and glazed appearance, indicative, in some degree, of subacute gastric inflammation. In this disease the stomach acquires the power of secreting air, which often takes place to an enormous extent; and if we press upon it towards its great arch, we shall find it somewhat elastic, and if we apply the stethoscope in this situation, we shall find the stomach tympanitic, and the sounds of the heart in this region become preternaturally clear and distinct. The reason of this is obvious. The stomach, being enormously distended with its gaseous secretion, irritates the heart, and throws it into irregular action, while the sounds of the organ are transmitted with preternatural distinctness through a medium so well adapted for their conveyance as the air, which is secreted by the stomach in its present disordered state. I have seen this form of functional heart disease, as I have remarked already, in persons who have led dissolute intemperate lives, addicted to excesses of every kind. I have seen more of it, however, in those persons who have returned from the civil wars in Spain than among any other class. I think that their mode of living while in Spain accounts satisfactorily for its very great prevalence among them. They were persons who, for the most part, were deprived, in a great measure, of a due supply of wholesome food; but who, in order to make up for this deficiency, addicted themselves to the intemperate use of stimulants of every class, such as green tea, tobacco, and, last not least, to the use of those which the country itself supplies with such lavish profusion—wine and brandy. Here we have all the causes necessary to produce gastric inflammation, and it is this which is the root of the disease.

We shall find the appearance of the tongue of material benefit to us in pointing out the treatment to be adopted, which is nothing more than the removal of the gastric inflammation which exists in a sub-acute form. In our treatment of this affection, our first step should be the application of counter-irritation over the epigastrium, and this continued, too, for a considerable time. For this purpose, I generally prescribe the croton oil liniment, made with a drachm of the oil to an ounce of spirit of turpentine, or compound camphor liniment. This is to be rubbed in every morning and night until pustulation is produced. Along with this topical treatment, I am in the habit of prescribing oxide of bismuth, in conjunction with bicarbonate of soda, or, better still, a combination of these two with the saccharine carbonate of iron in the following proportions:—

℞. Sodæ bicarbon. gr. x, Bismuth trisnitrat., Ferri c. saccharo āā gr. viij, pro pulvere, ter. in die sumendo.

This must be persevered in for some time, until the tongue becomes improved in appearance, the stomach loses its power of gaseous secretion, and the patient no longer complains of palpitation or any other irregularity of the heart. It will be needless for me to mention that, in addition to these means of cure, you must prohibit your patient most strictly from the use of tea and all other stimulants. Let his diet be one of a nutritious, non-stimulating character, containing animal food in quantity and quality suited to his enfeebled digestive powers.

I have next to call your attention to another functional affection of the heart, which, in some papers published in the *Dublin Journal*, I have called Epileptic Palpitation, and which, strange as it may appear, is always caused by diseases of the brain. It seems strange that an affection of the brain could cause palpitation of the heart, but, though strange, it is nevertheless true. You will be consulted by a young man, or by one probably in the prime of life, who will tell you that he has been attacked by palpitations for some time past, which render him uneasy, anxious, and uncomfortable, and that they come on him when he takes exercise or is at all agitated. These palpitations frighten him very much, but when you examine the heart you find its sound perfectly normal. On questioning him as to the first occurrence of this irregular action of the heart, he will tell you, perhaps, that some short time ago he was attacked with a fainting fit, which he says has recurred since, and that, after the first attack of syncope, the palpitations began to annoy him. This is what the older writers termed epilepsia silens—silent epilepsy. About the fainting fits themselves, the patient has not the least concern; he fears only for the palpitation, and to this he directs your attention exclusively. These fainting fits, if allowed to proceed unchecked, will terminate, perhaps in a very short time, in well marked and regular epilepsy. However, they may run on for a period of two years before the disease perfectly shows itself. Your attention will be awakened here by finding these fainting fits coming on at a period of life when they should be naturally absent, from the vigour which the constitution enjoys. You will, therefore, proceed to inquire from what cause it is that they arise. The heart, as I have said before, is perfectly normal in its sound; no disease there; no symptoms of irritation along the vertebral column. Where, then, does the mischief spring from? The head, as I have remarked, is the cause of these alarming palpitations, and of these fits of syncope which have preceded the palpitations.

We have now to consider the means best adapted to relieve both the cause and its effects. The medicine which I have found to possess properties the most serviceable and advantageous in arresting this disease is the digitalis purpurea, or foxglove. I have witnessed more benefit in cases of this kind from the use of the digitalis (bleeding from the arm having been in every instance premised) than from any other remedy or class of remedies which I have seen tried. To produce its beneficial effects here, you must not content yourself with administering it in the small doses of the pharmacologists. The form of the drug which I have found most beneficial is the powder; it must be given in doses of *two or three grains at bedtime every night*, and, in some cases, *in five grain doses*, until it exerts its peculiar effects on the constitution. You will, therefore, consider this affection of the heart only as it really is, one of secondary importance; and, in the selection of your remedial measures, you will proceed at once to strike at the root of the evil where it really exists—in the brain; and not until every trace of mischief has vanished from thence, *can* your patient be *free* from these palpitations, which are to him a source of such needless alarm. Without my having told you, your own common sense would at once have made you acquainted with the propriety of keeping your patient as free as possible from every source of mental irritation, as this has been known to prolong the disease to an extremely protracted period of time.

You will often meet, in persons of sedentary habits, an affection of the heart, consisting of violent palpitation, which, as in all these cases of functional derangement of the heart, give the patient a great deal of unnecessary alarm. There is no abnormal sound here, though the heart may be felt acting with great vigour. If we examine these cases minutely, we shall find, in every one of them, evidences of venous congestion; the pulse is full and quick, the eyes are suffused, the patient feels more or less drowsy; there are sometimes a turgescence and lividity of the face, and swelling of the legs, and, occasionally, an inclination to syncope. These signs, if neglected for any period of time, will terminate in an attack of apoplexy, in all probability fatal. It is easy to conceive why, in these cases, the heart should become affected with palpitations, in consequence of the extraordinary quantity of blood thrown upon it by the sedentary habits of the patient; these palpitations being nothing more than the struggles of the overloaded ventricle to discharge completely the quantity of fluid contained within it

The treatment here is obvious and simple. Take blood from your patient to the extent of eight or ten ounces, so as partially to unload the ventricle; after that give a purgative, so as to unload the alimentary canal; and, in my opinion, you will have done every thing requisite for your patient; in fact, you can do no more.

In concluding the subject of diseases of the heart, there may be others which I have not touched upon,

but, unless my memory fails me, I have given you every thing necessary for you to know on the subject. You may have thought me tedious, from the great length at which I have entered upon them, but particularly from the stress which I have laid upon functional disorders of the organ, which, probably, you may be inclined to set but little value upon; but I would beg of you most earnestly to consider the paramount necessity which exists that you should be able to distinguish accurately between these latter and structural diseases of the same organ, clearly resembling each other as some forms both do. Recollect the serious responsibility which attaches itself to you to be able to distinguish each variety of the diseases of such an important organ as the heart from the others; and that the effect of making a false diagnosis may be ruinous to your patient, and that while you are ordering a system of depletion, one of a totally different character may be necessary.

In every disease it will be incumbent upon you to know what other affections of the same organ may resemble the one which you are about to treat, in order that your patient may not be made a victim to a claim of pretended knowledge on your part, which you really do not possess.

COURSE OF LECTURES ON THE THEORY AND PRACTICE OF MEDICINE.

Delivered by C. J. B. WILLIAMS, M.D., F.R.S., Professor of the Practice of Medicine, and of Clinical Medicine, at University College.

The next disease to be noticed is small-pox. This, like other exanthematous diseases, seems to have been unknown to the ancients. It was first discovered in the fifth century, and it is a mystery where it came from. It seems that this terrible and destructive disease, soon after the discovery of America, was imported into that country as a sort of exchange for an infection communicated to us, which destroyed three millions and a-half of people within a very short period. This was the small-pox of Mexico. This is still a very fatal disease.

The natural disease is distinguished by two names, the *variola discreta* and *variola confluens*, according to the amount of the eruption. The latent state, and the state of incubation, vary from seven to twenty-one days. There may be that period before the fever begins. With the fever there is weakness, pain at the back, loins, and epigastrium, nausea, vomiting, giddiness, and headache. After the third or fourth day, the eruption may show itself; first on the face, the neck, and breast, and afterwards the joints, and then it extends to the limbs. It is often preceded and accompanied by a sort of rash, a diffused spotty patchy redness. This is one reason why the disease is mistaken in its early stage for measles, and sometimes for scarlatina; but there is this distinction: besides this diffused or patchy redness certain hard points may be felt—hard pimples under the skin, rendered rather painful on pressure. They are quite separate and distinct from each other at first. About the sixth or seventh day of the fever, and the third or fourth of the eruption, the pimples begin to show little vesicles upon them, especially on the face and about the cheeks, the forehead and joints, where the eruption first appears. These vesicles are irregular in their appearance. As early as the third or fourth day the interstitial redness disappears, and the redness becomes concentrated in these pimples. About the ninth or tenth day of the fever, and the sixth or seventh of the eruption, there is manifest a central depression, with an opaque double circle around it. On the eleventh day of the fever, and the eighth of the eruption, that which was before vesicular becomes opaque, more pustular; the matter contained in it becomes purulent, and now the central depression becomes more distinct. About the twelfth or thirteenth days of the fever, and the ninth or tenth of the eruption, the central depressions disappear, and the pustule swells out. About the fourteenth or fifteenth days of the fever, and the eleventh or thirteenth of the eruption, the pustules exude puriform matter, which forms scabs, and after this the scabs fall off, leaving pits in the skin, extending even to the cellular tissue; inflammation and redness may remain some time after. The course of this eruption is most distinct on the face, and it is quickest in its progress, and most complete in cases of the distinct small-pox, in which it begins sometimes earlier than the confluent variety. As to the general symptoms, about the fourth day the eruption is accompanied by great swelling, but the general redness may have subsided somewhat. The whole surface of the body, particularly the face, is very much swollen, and the fever, which is generally proportioned to the quantity of the eruption, diminishes when the eruption is fairly out. When the pock is fully formed, a secondary fever is apt to occur; the skin is hot, the pulse quick, and other general symptoms of fever, which increase. During this period new complications and dangers are apt to arise.

The difference between the confluent and the distinct small-pox appears to be ascribable to the different strength of the dose of the poison in the system. Where the dose is weak, and the power of reaction is strong, the eruption is small, and the health is less affected; when it is strong, there is great general depression.

In the distinct form there is generally less disturbance and less interruption, and there is commonly less reaction in the system; each pustule is more defined, and runs through its course more perfectly.

In the confluent variety there is more general disturbance of the whole system, and the pustules of the eruption are less distinctly separate—less characterised by circumscribed projections. The pustules, under these circumstances, spread and run into each other; the inflammation, also, which intervenes, is more of the erysipelatous kind, less phlegmonous and circumscribed in its character, and consequently there is more general swelling accompanying it, and great tenderness in the intervals. With this there are also proofs of the poison in the system—globular swellings, forming sometimes buboes—and the fever is more of the typhoid kind; the pustules do not swell out—they remain flat, and in many instances they do not suppurate; instead of going on to opaque suppuration in the advanced stage, before the eighth or tenth day, they remain filled with a serous fluid of a dark colour. These pustules, more like vesicles, extend to the mouth, the nose, the tongue, the pharynx, and the œsophagus, and occasionally the trachea, causing many uncomfortable symptoms. The salivation which is often present in small-pox is here very bad. There is difficulty in swallowing, hoarseness, cough, dyspnœa, with great accumulation in the trachea; much constitutional irritation and depression. Many sink under this state, from small-pox in the early period of the eruption; at least, before the secondary fever occurs. Sometimes the eruption presents a more thin and watery matter in the vesicles; and these are very bad forms of the disease, and are accompanied by the adynamic form of fever, and if the patients recover, their recovery is extremely tedious.

Sometimes the disease may excite the different varieties of fever, the ataxic, the nervous, and the congestive forms. Petechiæ sometimes occur in different parts, and the spaces between them are of a livid colour, with ecchymoses or effusions of blood. This is the hemorrhagic or petechial form of small-pox, and is a very fatal disease. It may take place as early as the fifth or seventh day. Sometimes you find effusions taking place in the brain, and other internal organs.

The greatest number of deaths takes place at the decline of the small-pox, which is very dangerous. These occur in connection with the secondary fever, various inflammations of the surface, and all sorts of complications. Erysipelatous inflammations of the surface and various parts, sometimes affecting the skin and cellular tissue; afterwards the inflammation, often becomes more circumscribed, forming boils, or even carbuncles; and sometimes abscesses, or infiltration of pus in the cellular tissue, sloughing and extensive sores. There is often, too, ulceration of the parts; all this proves there is irritation from the poisonous matter. The secondary fever is doubtless connected with an increased production of this matter. There are other inflammations besides this of a serious nature—ophthalmia, involving the structure of the eye, and sometimes sloughing and gangrenous inflammations of the genitals and the scrotum; various internal inflammations, pleurisy, pneumonia, laryngitis, and circumscribed inflammation of the lungs, and suppurative infiltration, or abscesses of the lungs. The membranes of the brain are sometimes inflamed in connection with secondary fever. These inflammations are very frequently latent, and are not obvious by permanent symptoms, and are chiefly to be found out by closely watching the functions and the physical signs. These inflammations especially show a suppurative tendency, and appear to be like purulent deposits. All these facts are proofs of mischief done to the system, analogous to that arising in connection with extensive burns. The pulse is often very frequent, and there is vomiting, delirium, tremor, syncope, and a dry, brown tongue, ending in death.

There are results of a more chronic character—various cachectic and scrofulous diseases; scrofula in its various forms is sometimes exhibited; the skin is generally left in an unhealthy state, and various other skin diseases sometimes result, such as ecthyma, impetigo, and ulcers of parts, particularly of the eyelids and about the joints; globular swellings, too, tending to slow suppuration of the scrofulous kind. Sometimes the patients, during the convalescence from small-pox, are attacked with a low fever of the typhoid kind, or erysipelatous inflammation; and it would appear that the weakness which has been produced by the small-pox peculiarly predisposes the body to these things. This has been proved in the Small-pox Hospital.

The sources of danger may arise, first, from the malignancy of the poison, which may manifest itself in the form of fever, becoming typhoid or petechial even before the actual eruption is very much declared externally; secondly, the malignancy may show itself in the confluence and quantity of the eruption, and it is quite certain that this is promoted sometimes very much by stimulants and heat. The cases that show any of these symptoms are the worst. The confluence alone, although it renders the disease more serious, does not necessarily render it fatal; for although the confluence is a proof of the strength of the poison, yet if the vital powers be strong, the system may bear up against the disease. We judge whether the bodily powers are strong by the pulse continuing of considerable strength, and not being very frequent—by the spots going through all the proper stages.

Then the danger may arise from another cause, that is, the complications; these may be in connection with, first, the fever, or with the eruption, as in the case of inflammation of the mouth and fauces; and secondly, they may occur in connection with the secondary fever. Patients in the secondary fever may die from the complications, or else from the exhaustion connected with them, from the fourteenth to the twenty-fourth day. This is one of the chief sources of danger, both because of the depressing or poisonous effect of the matter in the system, during the occurrence of the secondary fever, and because when the inflammatory complications occur, they are not here benefited by depression, and are not to be cured by depletion.

The cause of small-pox I need not dwell upon, whether it is by infection, or by contact, or by application to an abraded surface. Inoculation exhibits all the different modes of the infection; the infectious matter appears to exist from the first period of the fever, during the whole progress of the disease, until the disappearance of the last scab from the body. As long as there is a scab on the body it may be a constant source of infection. It seems certain that the infectious matter possesses a very volatile and strong smell, and persons have been affected by the effluvia from the dead body without any contact taking place; and thus small-pox has proved a source of pestilence. It is a remarkable fact that in some circumstances it spreads in some localities, and not in others. There is less predisposition required to receive this poison than that of other fevers, yet predisposition is necessary, for there are some persons who resist the influence of the small-pox, who never have even a modification of it during their whole lifetime. Others, again, take it very readily, and suffer more. It is more of this character in plethoric persons, of irregular habits of living, and in weakly persons. The fœtus-in-utero may take it, without the mother having any affection; the mother having had the disease before, and being exposed to the infection. When the mother

takes the disease, it is fatal to the fœtus, and it is very apt to be so to the mother too. Vaccination of the mother does not protect the fœtus, although the mother may take the disease, and communicate it to the fœtus; and although the fœtus may take the poison without the mother taking it, in regard to the natural small-pox, the same cannot be said with regard to the cow-pox, as that disease occurring but once in the course of the life, protects the system against its after occurrence, but not completely so here as in any other case.

Inoculated small-pox is another variety to be noticed. It is milder in its character, and there is actually much less amount of eruption, and the fever and all the symptoms are slight; the whole disease is of shorter duration, and there is, therefore, no wonder that it should be generally practised. Inoculation had long been done in the East, and it was from the East the practice was introduced into this country by Lady Mary Wortley Montague, in 1781. It was first practised on criminals, but the Royal Family set a good example by inoculating two daughters of the Prince of Wales. There was at first great caution used in practising it, and in the first eight years after its introduction into this country only 897 were inoculated, and out of these only 17 died. This was a very low mortality compared with the disease previously. As the inoculation was better practised it became more successful, and was in high vogue until the close of the last century, when its place was supplied by vaccination. The inoculation renders the disease milder, and partially accelerates and renders it shorter; the eruption appears about the seventh day instead of the twelfth, after the infection, and thus there is less time for the poison to be generated in the system, and the bodily powers are so much the stronger: where the disease is commenced in this way, it may supersede the natural disease. The natural small-pox is accelerated two or three days by the inoculated small-pox, and becomes milder. The chief precaution is, that the matter inoculated should be very small in quantity, and hence it was practised by needles and lancet-points slightly touched; the fifth and sixth day of the eruption was selected. It mattered not whether the disease was natural or inoculated, and it answered when taken from malignant cases. The eruption of inoculated small-pox was often very distinct and very scanty, and preceded, as in the other cases, by a rose-coloured efflorescence, but even where it was confluent it rarely extended to the throat. The general character was milder. It is stated that no malignancy was ever exhibited by any form of inoculated small-pox, and the secondary fever was comparatively slight. As a result of the inoculation, we find that the mortality of the inoculated small-pox was much reduced—to 3 in 1,000; whereas in the natural small-pox the mortality had been 3 in 10 cases.

Morbid small-pox is another variety to be noticed, as in some few cases it occurs a second time, the system not being perfectly protected from its recurrence. In this way, too, we have vaccinia, which also constitutes a morbid form of small-pox, and its chief difference is, that it is altogether milder than the others. The eruption is distinct and hard, the circumscribing inflammation is considerable, and instead of running on to vesiculation and pustulation, there are dry scabs, many of which die away without suppurating at all; the scabbing takes place a day or so before the complete suppression of the eruptive fever. The eruption is very limited; there are few pustules in most instances, and the inflammation does not go deep. The general health is affected for the first four or five days by the fever, but it is generally restored. The disease may discolour the skin very much; the eruption is very copious, and scarcely ever confluent; it may disfigure the appearance very much, but it neither tends to prolong suppuration and the secondary fever, nor does it cause any deep-seated inflammation, as in the other cases. If there are any pustules developed, they may generally be observed to have the characteristic depression in the centre.

The treatment of small-pox, first of all, in its natural kind, is to be founded on the character of the fever and the complications. In the early stage of the fever, a calomel purgative and an emetic are often of use to promote reaction, followed by antimonial salines and antiphlogistic treatment, observing coolness of the habitation, with free ventilation, quietude and rest. It is recommended by some to exclude light; they suppose that light increases the disease, and that it spreads very much under the influence of light, and this is the great reason why the hands and face are the most affected. It is certain that stimulants and heat make the disease more severe, and make it come out more in the confluent form. If there are signs of inflammation at the first outset of the fever, it may be necessary to bleed, according to the situation of the local inflammation, on the temples, the epigastrium, or the chest. In many instances there is a good deal of irritation where these complications are present, and with some amount of delirium, beating of the carotids, and contraction of the pupil. If the rash is retarded, hot pediluvium or mustard poultices to the feet and cold to the head should be used. When the rash is out and advances, it is of great importance to keep the body cool, but not cold, nor exposed to drafts, nor anything of that kind. If the inflammation passes to the extremities, it may be relieved by leeches. Where the disease is of the more depressed kind, stimulants, combined with salines, may be given. Stimulants ought to be given in considerable quantities, and this is particularly indicated if the surface is cold and the pulse frequent and weak.

Means have been tried to diminish the amount of the eruption; if this could be done it would be of great importance, not only on account of the disfigurement of the skin, but likewise to diminish the amount of secondary fever. The methods for this purpose have been greasing and rubbing the face with mercurial ointment and nitrate of silver, letting the matter out by puncture, and excluding the light.

In the secondary fever, the various local inflammations may be such as to require antiphlogistic treatment, but where there is great depression these measures are not well borne. Stimulants and tonics are often necessary in connection with the secondary fever, more particularly when it exhibits the adynamic type. With the stimulants and tonics antiseptics appear to be of considerable use applied externally; sponging the surface with a little vinegar and water, or *aqua sodæ chlorinata*, and as the surface is sometimes very sore and smarting, and great complaint is made on exposure to the air, it is necessary to apply a powder to the surface, or else cold cream. It is of great consequence to prevent the parts being unduly pressed upon in this disease. The more painful parts may be relieved by warm-water dressing; the hair cut short in order to keep the head cool, and because the exudation is likely to cause matting; the bed-clothes and patient's apartment should be sprinkled with a chlorinated solution or vinegar frequently, and kept cool and well-ventilated. For the same reason, the rules with regard to continued fever apply to this; take care that the secretions are kept free by mild aperients, and all excrementitious matter should be removed immediately.

If any of the parts show a tendency to slough, they require special treatment.

In convalescence, after the secondary fever has passed away, and even during part of its duration, if the patient is in the adynamic state, he may be benefited by warm sea-bathing, generally giving an aperient medicine to carry off the dregs from the system—iodide of potassium and sarsaparilla.

AN ESSAY ON THE VARIOUS FORMS OF ASPHYXIA, OR SUSPENSION OF SOME OF THE PRINCIPAL POWERS OF ANIMAL LIFE, WITH GENERAL RULES FOR RESUSCITATION.

By Dr. Chas. Clay, Piccadilly, Manchester.

(Continued from page 267.)

GENERAL CAUSE OF DEATH IN ASPHYXIA.

How the vital action becomes suspended, so as to cause death, is still an undecided question, about which authors differ very considerably. The impediment to the circulation through the lungs, by the cessation of the respiratory powers, does not appear to arise from the suspension of the mechanical motions of the chest, or from the venous blood destroying the contractility of the heart and large blood-vessels, but (as Dr. J. Reid expresses it) from the difficulty of transmitting the venous blood through the capillaries of the lungs; when the chemical changes have been arrested, the failure of sensibility, he says, arises from the accumulation of venous or unoxygenised blood in the vessels of the brain, &c. The object, then, should be to re-establish those chemical changes which have been arrested, and thus to prevent new changes more destructive to life from occurring.

On this subject Mr. Erichsen observes, "That one of the chief causes of the arrest of the circulation, is the obstacle offered to the passage of the blood through the lungs consequent upon the cessation of its arterialisation and the arrest of the respiratory movements, and that the contractions of the heart cease, and the functions of the brain and nervous centres become suspended, in consequence of the circulation of unoxygenised blood, deficient in stimulating and nutritious properties, through their tissues. Our first object should, therefore, be to arterialise the blood, and the second to restore or maintain the action of the heart, and thus cause the freshly aerated blood to circulate through the nervous centres, on which it acts as the most powerful stimulant, re-exciting the functions of the *medulla oblongata*, and the nerves of respiration, and thus enabling the respiratory movements to be properly maintained, and, consequently, the oxygenisation of the blood to be naturally performed." Much interesting matter on this subject will be found in Dr. Kay's work on Asphyxia, and in the article "Asphyxia," in the *Library of Practical Medicine*.

GENERAL REMARKS ON THE MEANS OF ARTIFICIAL RESPIRATION.

It will be necessary to introduce a few general observations on the manner of effecting artificial respiration, before speaking of its application in particular cases. In urgent cases (and all cases of suspended vital powers must be urgent) the simplest means, and those which can be commanded under almost every circumstance, and are applicable to every situation, are decidedly the best and most to be relied on. A pair of common bellows is, perhaps, the best and most available instrument, after all, if properly applied. The point of the tube must be inserted into one of the nostrils, whilst the other nostril, as well as the mouth, is effectually closed; the lungs are then inflated by the bellows, and now the operator must adopt means to expel the air he has just sent into the lungs; for this purpose the bellows must be removed, and pressure with the hands spread over the surface of the chest is generally resorted to; but by far the most effectual plan is to take a piece of calico, about half a yard broad and two yards long, the ends of which are to be torn up into shreds to the number of six or seven, keeping it whole in the middle, which part is applied to the back of the chest, and the torn ends cross each other over the top of the chest. Two assistants, one on each side, having the ends of the calico in their hands, can by extension produce a very equal pressure on the chest, closely imitating the natural action of breathing, and thus easily expel the air sent in by the bellows. The bellows, with the bandage, should work alternately, which may easily be done by a little activity. From time to time the operator should endeavour to ascertain if any natural action be set up, for which purpose, if the stethoscope is not at hand, the ear is equally good, when applied over the region of the heart, &c. Many plans have been proposed by various persons as improvements in artificial respiration, some of them entitled to great praise for their ingenuity; but it must be confessed, however effective they may be in restoring the powers of life, which cannot be questioned, yet it happens unfortunately that cases to which such means are most applicable, are many of them so situated that they are in a great measure *inapplicable*. The question is really, *not* so much what is the best, but what is to be preferred of those means which are at hand. It is, however, only justice to their ingenuity to give them a place here, in order that, if an opportunity should present itself where they can be put in requisition, they may not be neglected. One of the means proposed is warm air, in lieu of cold, as the object is unquestionably to promote warmth, as well as restore mechanical

movements to the chest. It is very desirable to substitute warm air when it can be done without sacrifice of time. An additional supply of oxygen gas to the air used for inflation has been proposed also by others, but I am afraid the objection just started against warm air is equally fatal against the latter proposition, namely, the consumption of valuable time, as well as the difficulty of obtaining it when wanted. Nevertheless, the suggestions are valuable for a suitable time, and, therefore, ought not to be lost sight of. If oxygen imparts warmth to the system, the principle of its application is legitimate; but if, as some have supposed, the action of the air on the lungs is purely mechanical, then it would be of little consequence to add oxygen to the air for inflation. Again, if purely mechanical, the expired air from one person's lungs might be used for inflating the lungs of others with impunity, and, on account of its warmth being always present, this would be preferable to any other; but that this is not the case common sense would dictate, that air rejected as unfit by one system is equally so for another, particularly when the one to which it is applied is so nearly defunct that any deleterious or injurious principle, however trifling, would have a very powerful effect in extinguishing the feeble remains of animal life. Electricity and galvanism are undoubtedly very powerful agents, and well calculated to restore animation, but, like the means just spoken of, an electric machine or galvanic trough is not always at command; indeed, but very seldom where resuscitation is most frequently required to be practised, for it must be remembered that suspended animation from design, or the character of the accident, frequently (indeed mostly) occurs in isolated and unfrequented spots, where philosophical means, and minds to apply them, are much rarer than the circumstances that call for their use. With these considerations, it is evident our best hope must rest on the judicious application of the simplest means, and such as can be understood and put in practice by the meanest capacity, and are at the same time immediately at command.

In asphyxia it is necessary to bear in mind the difference in the treatment required between those cases where the action of the heart is still continued (though feebly) and those where it has ceased altogether, otherwise syncope may be confounded with real asphyxia. In syncope the impression is upon the nervous system, the heart continuing its action, and depending on the small remains of oxygen in the lungs—animal life suspended, but organic existence continued. In real asphyxia the impression is first on the respiratory and circulatory systems; the nervous system being only secondarily affected, the blood rapidly becomes venous, and no longer stimulates the heart. Thus a very different treatment is called for. In asphyxia the blood must be re-oxgenised. In syncope the nervous system must be roused. In syncope the action of the heart is carried on very feebly for an indefinite period. In asphyxia it ceases altogether very rapidly. To the questions, "Can artificial respiration re-establish the circulation through the lungs after it has entirely ceased—or excite the heart to contract when once it has given up doing so?—Mr. Erichsen and Professor Sharpey reply, that after the action of these organs has entirely ceased, and they become congested with asphyxiated blood, they can be restored. Mr. E. adds, that four minutes is the longest period of cessation of action from which restoration can take place.

ASPHYXIA OF NEW-BORN INFANTS.

At first sight it may appear unnecessary to treat of infant asphyxia in an essay designed for general use, but when it is considered that thousands of infants are born without any person being present capable of rendering efficient assistance, and the number still greater born with only the assistance of females, also that a large portion of asphyxiated births occur where little or no assistance of an efficient nature is rendered, a short space devoted to this particular subject will not be deemed irrelevant, and may possibly lead to extensive preservation of human life.

CAUSES OF INFANT ASPHYXIA.

Asphyxia of new-born infants may arise from different causes, separately or combined; pressure on the cord or navel string, during the efforts of child-bearing preventing a due circulation of blood to the child; pressure on the brain of the child, by coming too powerfully in contact with the bony parts of the mother; plugging up of the respiratory passages with mucus; dividing the navel string too early, before the respiratory process is properly established in the child; general constitutional debility; and lastly, the effects of deleterious substances given to the mother during child-birth, some of which are often given for the purpose of facilitating birth, such as ardent spirits, &c. I may also add, that the ergot of rye, *when given in substance*, has a tendency to produce asphyxia in the child—a circumstance that does not appear to attend its exhibition when given in watery infusion (for particulars respecting which I refer the reader to the sixth volume of the *Medical Times*, pages 356 and 371.) Any one of the causes above mentioned is sufficient to account for the asphyxiated condition. As it is a circumstance of very frequent occurrence, it is the more necessary to point out the treatment, particularly as a large proportion of these cases happen when professional aid is absent.

TREATMENT.—There has been, and still exists, a variety of opinions on the treatment of infant asphyxia. Dr. Scholer, of Berlin, is persuaded that immersing the child in cold water will often be successful. Popular feeling would run against such a practice in this country; but its merits (if it has any), should not be disallowed on that account. For my own part, I should think it a very hazardous experiment, and not very likely to be attended by successful results. Dr. Marshall Hall, whilst he advocates the sudden application of cold to the face and chest, by blowing and dashing cold water upon them, yet advises the rest of the body to be kept warm; also inflating the child's lungs, by expiring the operator's breath, through the pores of a cloth, into the mouth or nostrils of the infant.[1] I can easily conceive how the sudden application of cold would, by causing contraction of the muscles of the chest, facilitate the motions required for respiration (it being well known that a sudden effort of inspiration occurs, whenever water is dashed on the face or chest of an adult in health), and reasoning from analogy, the same will undoubtedly take place in the infant. Thus, to a certain extent, the sudden application of cold air or water is not only desirable, but necessary. But I cannot so fully accord with the practice of inflation of the child's lungs by the expired air from the lungs of the operator, until it be clearly proved that the action of the air upon the lungs be merely mechanical, even although the plan of inflation include the precautions of Dr. Marshall Hall, which are as follow:—"The practitioner's lips are to be applied to those of the infant, interposing a fold of linen, and he is to propel the air from his own chest, slowly and gradually, into that of the infant, closing its nostrils, and gently pressing the trachea on the œsophagus. The chest is then to be pressed, so as to induce a full expiration, and allowed to expand, so as, if possible, to effect a degree of inspiration. But it is important, in doing this, that the practitioner himself should previously make several deep and rapid respirations, and finally a full inspiration. In this manner the air expelled from his lungs into those of the infant, will contain more oxygen, and less carbonic acid, and consequently be more capable of exciting the dying embers of life."

This celebrated physiologist then admits the oxygenising power of respiration. Now, on such a supposition, the effects of carbonic acid are considered injurious, to which the lungs of a new-born babe must be exquisitely sensible, though the portion of carbonic acid may be very trifling. Having made these observations, let the following be understood as what appears best to be done with children born in the asphyxiated state.

1st. The navel cord should never be separated until the pulsation from the mother has ceased. The neglect of this precaution I am confident from long experience is the cause of a great portion of these cases.[2] 2nd. The mouth and nostrils should be cleared from every particle of mucus, which in many cases is so great, as entirely to stop the respiratory efforts. 3rd. The tongue is found turned upwards and backwards, so as to act like a closed valve to the entrance of the air passages to the lungs; it is therefore necessary to open the infant's mouth, and press the tongue down with the tip of the finger, and at the same time draw it a little forward; the atmospheric air then finds free access to the entrance of the trachea or windpipe. By this simple means, I have restored many cases of infant asphyxia. 4th. Inflation of the lungs, on the principle proposed by Dr. M. Hall already alluded to, or in the following manner, which I believe to be more effectual, and which avoids the possible deleterious tendency of inspiring air that has been once expired. I take the common clyster India rubber bag and pipe, which holds about as much air as the lungs of an infant; I insert the pipe into the mouth, or, if small enough, into the nostrils, which is better; the rest of the passages being closed, the clyster bag is pressed, so as to expel the air contained in it into the lungs of the infant; the pipe is then to be withdrawn, when the atmosphere again fills the bag, which can be repeated as often as required. When the pipe is withdrawn, the expiratory process must be assisted by pressing the surface of the chest, &c. Where the India rubber bag is not at hand, the small pair of bellows used for dusting will be found an admirable subsitute; when bellows are used, they must always be removed from the nostrils while filling with fresh air; and where neither are to be obtained, then the operator may substitute his own expired air, but which, I believe is to a certain amount objectionable, and only to be used when better means are not at hand. 5th. Friction, particularly over the chest, with the warm hand is often of service. 6th. Dipping a cloth in cold water, and suddenly dashing it on the chest,[3] is frequently the means of exciting a sudden inspiration; and in consequence the respiratory organs commence their natural operations. 7th. The rest of the body should be wrapped up warmly, but not be put in the warm bath, as is a common custom. Dr. Edwards has shown by numerous experiments the bad effects of the warm bath. He maintains that the oxygen is consumed, and the necessity for respiration keeps a direct ratio with the development of animal heat; and likewise, that the application of heat to the body increases its power of developing caloric, whilst the abstraction of heat by means of any cold medium, has a contrary effect. Every one may observe, that when the body is heated by exercise, or by any other cause, the necessity for respiration becomes much increased, and that breathing cannot be stopped for more than a few seconds, without inconvenience, and even danger. Now, it is the stoppage of respiration that is the cause of mischief in drowning, as in every case of asphyxia; and withdrawing a person from the water would be of no avail unless respiration were re-established; for otherwise the process of asphyxia would be going on; and therefore the warm bath, by putting the system in a state which requires more oxygen, would hurry on the process of death, *if it did not at once cause the act of respiration* to commence. Thus the common, *nay*, almost universal practice of immersing the infant in warm water, is in all probability attended with greater mischief than good; yet, I am aware of the difficulty of convincing the world to that effect, in the face of a generally received custom, and supported by a large proportion of the medical faculty. It is certainly a matter worthy of serious

[1] It is probable a similar practice was enforced by the ancients. We read in Scripture of Elijah's acts of resuscitation, 1 Kings chap. xvii. ver. 21; but still more pointedly in 2 Kings chap. iv. ver. 34.

[2] In waiting for the pulsation of the cord to cease, care must be taken not to confound the independent circulation of the child with the joint circulation of the mother and child; for the impulse of the true circulation of the child will extend some inches along the cord, and it is therefore necessary to test the cord *at a considerable distance from the umbilicus*, to ascertain if the natural connection has ceased. If it has, the division may take place, although pulsation may be strong in the cord near the umbilicus of the child.

[3] Or moistening the surface of the chest, and blowing suddenly on it with a pair of bellows.

consideration.[4] 8th. Pungent stimulants to the nostrils should be applied. 9th. Irritating or tickling the fauces and nose with a feather or bristle. 10th. If the child be plethoric, a tea-spoonful of blood taken from the navel string will probably restore it. 11th. Electric sparkling, as well as galvanism, may be applied with advantage, if the apparatus be at hand. Their application with judgment, also requiring professional information, can only be used efficiently by medical men; still they are remedies that must not be lost sight of, as they are valuable in cases where a long time has elapsed, and no progress been made. The state of the atmosphere may render electric operations very uncertain. Those latter remedies may be practised a full hour or more after birth, and with a probability of success.

Then, as to what must not be done. The cord must not be divided till the pulsation has ceased; expired breath of the operator must not be used, except when other means are not at hand, as bellows, clyster bag, &c. We must not omit to press the tongue downward, and forward with the finger, to admit the air into the trachea; otherwise, you may be inflating the stomach instead of the lungs. Never bleed from the cord if the child be a weakly one. The use of the warm bath is questionable. In the absence of clyster bag, bellows, &c., do not forget to apply the mouth to the child, or, if this be objected to, a female catheter, the barrel of a quill, or stiff paper rolled up as a pipe, are all good substitutes in an emergency.

To conclude these observations, this chapter may be esteemed a little out of the path of the humane societies, but can those bodies so conclude when informed, that one child out of every twenty dies from asphyxia at birth? that a vast proportion of births are attended by illiterate females? that many are born with only the presence of relatives or friends? and lastly, it is surely as legitimate an object of humanity to save the life of an infant in the commencement of its existence, as it is to restore the adult from the asphyxiated state, particularly when the fate of that infant may involve the fate of an anxious and suffering mother at the time, who at all events must be esteemed a valuable member of the community, and worth a struggle to save.

THE CURATIVE POWER OF MESMERIC INFLUENCE PROVED BY ITS SUCCESSFUL APPLICATION IN A VARIETY OF EXTREME CASES.

By WILLIAM WARENNE, Lecturer on the Physiology of Health and Disease, Hull.

[We forbear in any way to identify ourselves with either the theories or alleged facts of this extraordinary paper. The statements appearing with the name of the writer, a medical Teacher, are published with a serious responsibility, and being very specific, cannot, we hope, escape a searching scrutiny. Whatever the result, we shall have no hesitation in promulgating it.—Ed.]

Mesmerism having now become a scientific as well as a public consideration, more worthy by its proved utility than by its hitherto unaccounted-for phenomena, I consider it my duty to lay before you a few cases, selected from a great number, in which successful results have been attained, through the exciting or sedative nature of mesmeric influence, or, as it has been termed by some, animal electricity. In common, I believe, with all persons who have practised and reflected upon the phenomena and utility of mesmerism, or, as it is termed by Mr. Braid, of Manchester, hypnotism, I admire that gentleman's labours, and his bold and straightforward avowal of his opinions, and consider him entitled to the thanks of the members of the faculty for the extensive range of information which he has in various ways placed before them and the public; and though I feel obliged to differ from him in some of his conclusions, arising probably from a difference in our mesmeric state, or in that of our patients, yet I feel happy in being enabled, by a most extensive course of experiments, to bear out his testimony to the wonderful utility of mesmerism as a curative agent. I may here be permitted to say, that in all the wonders I have witnessed in connexion with mesmerism on the continent, before and since its introduction into this country, I never detected or had any reason to suspect frauds; though in all I have seen, and in all I have since practised, I have felt myself (as every body else has) entirely unable to account for the phenomena, and the more so, as I found them so differently exhibited in different persons, and in the same persons at different times; but with regard to the facts of its curative agency, where no fraud would be suspected, I have had and have produced so many proofs, that my refusing to acknowledge them would be refusing the evidence of those faculties of sense and reason which elevate us above the lower grades of creation.

I may here also remark that I have frequently tried, but never succeeded, in producing mesmeric phenomena by the means recommended by Mr. Braid; whilst by the usual method, that is, by contact, I have never failed. This suggests to me that there may be a difference in mesmeric influences residing in the mesmerisers, consequently, my want of success in adopting Mr. Braid's method, does not lead me to question his statements, and experience has taught me that, to send the patient into that state of unconsciousness termed mesmeric trance, is not in all cases necessary when mesmerism is applied as a curative agent. I differ from Mr. Braid in his opinion that the influence resides entirely in the patient. I have, as the following cases will best explain, been led to think that the electrical power passes from the mesmeriser to the patient, and I think it will be found upon more mature consideration, even in the cases which Mr. Braid has observed and reported, that the mere will of the mesmeriser most directly influences the actions, and I think also the words and thoughts of the mesmerised.

Before detailing the cases in which curative means have been so successfully employed, I will lay before you a few instances which I think will bear out my allegations, that mesmeric influence must pass from the operator. I have frequently affected persons through a wall, with various states of somnambulism; they being quite unaware of my intention. In one instance, when my assistant was engaged in another room in operating on a patient, by my unintentionally stretching forth my hand in the direction of the above, both the operator and patient were instantly mesmerised; my assistant came into the room to me, in what is termed by Mr. Braid the "exalted state," a state which I had never before produced in the same person, even by powerfully mesmerising him with contact and an hour's manipulation of the cerebral organs. On the same evening I mesmerised through the wall a young person whom I had cured of paralysis: she had her hands clasped; I called my housekeeper to view the case, and as she entered the door, I stretched out my hand, in order to caution her against making much noise, when she became instantly mesmerised, with her hands clasped in the same position. What could imagination have to do in these cases?

A young Quaker gentleman, whom I placed under the care of my housekeeper to be mesmerised for epilepsy, though at first very difficult to be affected, yet became so susceptible, that, if upon entering a room I pointed my finger at his forehead, he was instantly mesmerised: from a room above him I could, by pointing my hand downward, raise him off his chair to his feet; and by raising my hand oblige him to spring upward higher than he could at any other time; he being quite awake, and not aware of my presence in the apartment above him. When placed in a Bath carriage, I pointed my hand towards him (being behind him at the time), to ascertain whether I could move the carriage with him, when immediately he flew a great height from it, falling to the ground unhurt. What could imagination have to do with this? At another time, when I placed myself behind a brick column, three feet thick, and about twelve persons between him and the column, on pointing my hand (quite unseen by him) he was so attracted as to force these people before him into a heap. Here imagination cannot be supposed to have any influence! If the fingers were pointed at his forehead, he was instantly mesmerised; if at his body, irresistibly attracted, but not rendered unconscious.

I experimented with two patients at various distances, and found that the greater the distance the more rapid and powerful were the effects of mesmerism. I had one patient conducted nearly one quarter of a mile, and the other placed about half that distance; the farthest off was kept in conversation by a person on each side, yet none of the parties were aware for what reason they were sent to a distance. When I could barely distinguish the central person of the foremost party, I stretched out my hand in the direction of the three, when immediately the farthest off fell, and the other directly afterwards; both were rendered cataleptic, and felt, they stated, as if slightly tripped, as the effect came from the feet.

At a party of about thirty Quaker friends, who were desirous of investigating the phenomena, I presented two patients, who, being placed at opposite sides of the room, with a chain of connection formed by the Friends, stretching from the left hand of the one to the right of the other, were both thrown down and rendered cataleptic by my stretching my hand in the supposed line of the patients, whilst in a distant room. They dragged with them several of their friends, some of whom declared they felt a shock pass through their arms. This sensation in the Quakers may have been imagination; but the two patients, by some means, before I got into the room, had their heads so fixed to each other by the crown, that I was some time before I could relieve them from a situation apparently, though not really, painful. What in this case is most worthy of notice is, that one patient fell from the other towards the position of the operator.

I have frequently performed similar experiments while the patients were in an unconscious mesmeric state, where it must appear very evident that imagination could have no effect. The same patients, being mesmerised, conversed fluently, assisted themselves and others whilst at supper, and one of them, yet under the influence of mesmerism, mesmerised a young gentleman, proving that mesmeric influence must pass from the operator, independently of the staring of the eyes.

One of the same patients, when the organ of order was touched, took from my hand a handkerchief, went to a corner of the room, there dusted the several articles very carefully, and returned each to its respective place; it being remarked by the servants, at the time, that this was the only part of the room that had not been dusted. On different coloured papers being presented to him, he immediately named the colour of each without the aid of any light, calling white no colour. The same two patients were taken home, still in a mesmerised state, when, without turning their heads, they read with perfect ease across a broad street the signs and placards which those who accompanied them could not see, though they were aware of their situation and existence.

It may be remarked, that one of the patients was an entire stranger to that part of the town, therefore memory could not be an agent. I may also state that, whilst the patients were (not being mesmerised) kept in conversation at the extreme end of the room *by the volition of thought*, as requested in writing, I could render the leg or arm cataleptic. Imagination could not here be the agent; yet, whilst I could do all this, and much more, I could no more account for the power I exercised than could those who obeyed so unconsciously and irresistibly my agency. In placing before your readers the following cases, as illustrative of mesmerism, I cannot be suspected of wishing to deceive, or of having any interest in supporting a deception. What I present is to the profession, and I offer to furnish references (to the patients) to all who wish more fully to investigate the facts I present. I have, like, I believe, all the medical mesmerists who have experimented and written on the subject, made the experiments a my own expense, with a desire first to learn, an secondly to make known, their useful results hoping to extend the "practitioner's power over

[4] If the skin act as a respiratory organ (and to a certain amount it does), it may be considered as an assistant to the respiratory function. A warm water bath therefore is highly objectionable; but a warm air bath would in all probability be attended with good results.

conditions of disease hitherto considered beyond the reach of medicine. Upwards of thirty-three years of extensive and onerous labours for the diffusion of medical knowledge, with an undeviated attention to the state of society, and an ardent desire to improve the condition of the poor by explaining the causes of disease and the means of securing health, holding official situations which, whilst travelling, enabled me to observe the endemic, and, when resident, to trace the causes of epidemic diseases in one of the largest cities in the empire, will, I think, be considered as entitling me to judge of results by a competent investigation of their causes, and, therefore, to be a person not likely to embrace theory not formed on a chain of illustrative facts: having in relation to mesmerism, both in its phenomena and its utility, made this investigating principle my rule of procedure, I feel therefore a proportionable degree of confidence in submitting to the judgment of your readers the following cases, in which the cure depended more on mesmeric and magnetic influence than others in which constitutional treatment being combined to some extent might be considered as partially effecting the cure.

Case 1.—A young lady now residing in Hull, but at the time when the cure was performed in Pocklington, lost gradually, but entirely, the use of her lower extremities from the effects of a fall; she was incapable of turning on her side in bed, and, to have the bed made, was obliged to *be* turned over; not being able to sit up, she was fed on her pillow, continually lying on her back. When I saw her she had been in this condition two years and a half; her lower extremities having withered to skin and bone. When delivering a course of lectures at Pocklington, I was requested to visit her. Upon inquiring of some of the resident medical gentlemen the nature of the case, I was told they had not been consulted, as persons of higher pretensions in spinal cases had been employed from different parts of the country; but from what they could understand, the case was pronounced to be hopeless, as the mother would not allow of issues, setons, &c., all other means having been tried and proved useless. Upon examination, I conceived the case might give a trial to mesmeric treatment, as all other means had failed, and the patient had been left to her fate.

After spending a few days making experiments, which were encouraging, I instructed the mother and sister how to carry forward the operations; their readiness to learn, and their persevering dispositions, gave me such confidence that I promised as a reward for their exertions, if continued, that in three months the patient should walk with me through the town.

In six weeks afterwards I returned, and found my patient so improved, that I ordered her out of bed, and walked with her several times across the room. I need not describe the wonder of all, mixed with pleasure, which cannot be rendered into words. She, after this, rose daily; the means were continued with more visible effects, and in six weeks afterwards, completing the three months in fulfilment of my promise, I walked with the patient through the town, affording to none of the inhabitants more surprise than to myself. The means used had been simple, yet effective. This lady is now enjoying the most perfect health. In this case, pain in various parts of the spinal column was the only sense of feeling connected with the disease, and the only remedies previously applied went to the seat of the pain, which shifted from the lumbar to the dorsal regions alternately as the means were applied; the catamenia, which had been suppressed for upwards of two years, returned shortly after the young lady's recovery. I may here remark that, in catamenial suppressions, I have witnessed the success of mesmerism, where the most powerful emenagogues had failed.

Case 2.—A young girl, aged between nine and ten, was nineteen weeks afflicted with St. Vitus's dance; she had been visited by most of the medical men, and viewed as a curiosity. The disease having resisted the common range of antispasmodics, and therefore, as a case deserted, been left to nature, I considered it as a suitable one to put mesmerism to the test. I found the child bound hand and foot, to prevent violent and uncontrollable actions, which would have endangered her life. Loosing her bonds, I took her on my knees, and, after only manipulating her nerves for about three quarters of an hour, I put her down cured, and so she has remained ever since.

I have lately had a similar case, a girl, aged fifteen, but suffering under a second attack, she first having been treated by the usual means. In this case the brain was affected, so that the patient was idiotic. I pursued the same means as in the former case, but the girl, having to be brought from a distance, I instructed the mother, and after a little time, to our great surprise, we succeeded in producing a splendid cure, such as could not have been expected by any who had witnessed her idiotic and excited state, which yielded to the means chiefly applied by the confident hand of the parent. Thirty years ago I saw the nuns of some convent cure children of various kinds of fits, by manipulation and prayers. Having paid more than ordinary attention to the nervous system, I attempted the manipulating process without the prayers, and succeeded, so this is not a new discovery: and by the same means I have enabled mothers to prevent, and often cure, decided cases of hydrocephalus in infants. Mesmeric influence, if it can do any good, is surely worthy the attention of medical practitioners.

Case 3.—A boy, aged eight years, was brought to me, his limbs supported by irons, his spine laterally curved at its base, his shin bones forming an arch, his thigh bones of course distorted, and his belly nearly touching the ground; he was the only son of a lady, whose husband was lost at sea; all had been done that medical advice had been able to afford; and the iron assistants were the last. As an extreme case I tried mesmeric means, instructed the mother how to proceed, and, aided by some constitutional treatment, our joint efforts succeeded. The boy is now not only straight in his back and limbs, but is remarkably healthy, strong, and active.

* [Our correspondent narrates several other cases of a parallel kind, and concludes with an emphatic appeal for the further investigation of Mesmerism. For ourselves we have only to repeat, that these statements *demand* the particular scrutiny of the medical men resident in Hull. We need not say that our columns are at their service.—Ed.]

IMPORTANT MEDICO-LEGAL CASE.

To the Editor of the Medical Times.

Sir,—The anomalous nature of a medico-legal case which lately occurred to me, induces me to request a place in your columns for the following brief outline thereof.

Yours, obediently,
Butler Lane, M.R.C.S.
Ewell, Surrey, August 3, 1845.

I was summoned early in the morning of the 20th of June to a house in the immediate neighbourhood, in consequence of the discovery of a new-born child, which it was supposed had been given birth to by one of the servants, an unmarried female ætat about 21. On attending, a fœtus was shown to me wrapped up in some under clothing, and I then judged it to be of about seven months' gestation. The woman, who seemed of rather weak intellect, had, I understood, denied in the first place that she had "*given birth to a child,*" though, when it was shown to her, she appeared tacitly to acknowledge the fact to her mistress. She did so likewise to me, and also informed me that she had not expected to have been confined so soon. She did not think that she became in the family way until after Michaelmas, but could not fix the exact date, and she considered that she should have returned home in time for the event. (She was to have left her place some days previously, but had agreed to remain another week for the accommodation of her mistress.) She assured me that she had not been in the family way before.

An inquest, of course, was required, and in pursuance with the coroner's order, I examined the body of the child. It was that of a female. The placenta was unsevered; it was of moderate size, but loaded with fat, especially on the fœtal surface; the entire of the membranes were connected therewith, and appeared dense and thickened. The funis was between five and six inches in length, and seemed to have undergone no laceration or stretching. There was not much appearance of hemorrhage. The child was singularly emaciated, measuring sixteen and a half inches in length, but weighing scarcely three and a half pounds avoirdupois. The head was of small size, but tolerably firm. The cutaneous surface was fresh and healthy, presenting no mark of injury or discolouration whatever. The central point of the body was within half an inch of the umbilicus. The membrana pupillaris had disappeared. There was some slight growth of hair. The nails were fully developed. These circumstances convinced me that my original supposition of its being but a seven months' fœtus was incorrect, and that in accordance with the woman's own statement it was at a period of at least eight months. The thorax was contracted. On examining the lungs, not the slightest symptom of respiration having occurred was discoverable. They were closely adherent to the posterior mediastinum, and their substance was of uniform hepatic texture, without the slightest appearance of cellular development. Submitted to the hydrostatic test, both entire and in small portions, they sunk instantaneously in the water. The still birth of the child was then beyond doubt, and solely to that effect was my evidence at the inquest, with merely a few additional remarks as to the birth being premature, which supported the woman's statement of expecting to have returned home before the birth took place, and would account for no preparation having been made; also as to the small bulk the child occupied, and the consequent facility of parturition. Three other witnesses were examined: one (a fellow servant) deposed to having suspected pregnancy, and seeing stains of blood, she communicated her fear that something was wrong to her mistress, by whose order she made search, and *found the child* concealed in a box under the woman's bed. The mistress, on the other hand, deposed to *receiving the child*. It appeared that the birth took place within from half an hour to an hour after the woman had retired to her room at night, she having been somewhat poorly all day. The following morning she was up and about, when the discovery was made. In accordance with the evidence, a verdict was of course given that the child had been still born, with the additional finding, that the woman was guilty of concealing the birth. She was, in consequence, to be held in custody by the police until such time as she should be fit to appear before the magistrates.

A remark having been casually made in the course of conversation respecting "*some skin*" which covered the child when first found, by the mistress of the girl, I was induced to make further inquiry, and to my surprise I learnt, that on the first discovery the child was completely enveloped by the membranes in a state of integrity, and that it was only subsequently to the discovery that the ovum was torn open, laying bare the child as when shown to me. The lady also informed me, in answer to my questions, that she could not see the child in the first instance, nor any portion of it, neither could she discover the shape thereof, but from her matronly experience she supposed the substance to contain a child, and therefore opened it. On questioning the second witness, the fellow-servant of the accused, she also acknowledged to having been unable to see the child previously to the membranes being opened, though she thought that she could distinguish the outline of the form. She had, in fact, made up her mind beforehand that it was a child, and having had no experience in such matters before, she probably thought it the usual manner in which children were born—from eggs, like chickens. A very few minutes certainly elapsed between the discovery of the substance and its being opened; so short, therefore, was the period of ignorance or doubt, and, in the confusion and excitement of the moment, that period was so slightly defined that its recollection might readily have been swallowed up and obliterated by the after certainty of the matter. Therefore the knowledge of the true state of the case would seem to the parties existent throughout, the ascertainment of the fact connecting itself with the anticipation thereof. Thus the original incorrectness of the evidence could be accounted for, at the same time that it became questionable how far the second witness was actually cognisant at the time of the true state of the case. The expulsion of

the ovum entire after the eighth month is decidedly rare, but at an earlier period it is not uncommon, and not even a professional man can always predicate with absolute certainty as to the nature of the fleshy membranous mass which is presented to his inspection. I remember on one occasion being suffered to carry off a seven months' ovum, the impression on the minds of the nurse and female attendants being that it was merely a mole, or false conception. These circumstances at once made it doubtful in my mind whether the woman was aware at the time that she had given birth to *a child;* if she were *then* ignorant of the fact, she could not be guilty of any *wilful concealment.* I considered that if the possibility and probability of ignorance in the matter could be established, the woman should of course be entitled to the benefit of the doubt, and be relieved from the minor penalty for concealment of birth. I have already mentioned, that when first accused of having given birth to a child, her reply was that it was "*not a child.*" I now questioned her further, without letting her know the object of my inquiries. Her statement was, that she had felt poorly all day, as she had always been accustomed to do on the approach of the menstrual period; that she suffered but little pain when the substance came away, and thought it merely congealed blood, having no idea of the presence of a child (which, under the circumstances, would readily go "in very little compass, round or square"), until it was shown to her by her mistress the following morning.

In a few days the woman was taken before the bench of magistrates. In consequence of my statement the matter was fully investigated, and the facts I have detailed were elicited. It was then decided that the concealment of birth was not proved, and the woman was consequently discharged.

PROGRESS OF FRENCH SCIENCE.

(FROM OUR OWN CORRESPONDENT.)

Paris, August 1, 1845.

On the Treatment of Internal Hemorrhoids.—When we consider the numerous accidents which follow the operations performed for the cure of internal hemorrhoids, and reflect that excision, on account of the danger of fatal hemorrhage, is universally dreaded, any method by which a radical cure of this painful disorder can be obtained deserves attention. Dr. Amussat, whose laborious researches are so well known, and whose zeal for the advancement of science knows no bounds, thought it possible to obtain a cure by means of the ligature, without exposing the patient to the dangers attendant on the operations previously had recourse to. For several years he employed it exclusively in a great number of cases of internal hemorrhoids with perfect success; but as it offered some slight disadvantages, on the discovery of the solidified Vienna caustic by M. Filhos, he substituted cauterisation for the ligature, in order to avoid the nervous disorders which sometimes occur, owing to the constriction produced by the latter, and to simplify as much as possible an operation which is so often required. A great number of patients have already been operated on with this caustic, which consists of a cylinder composed of solidified potass and lime, and the effects were far less serious than when the ligature was had recourse to. At first, Dr. Amussat seized the hemorrhoidal tumour with a pair of dissecting forceps, so as to enable him to cauterise it more easily; but in April, 1844, his son, M. Alphonse Amussat, thought that the circular cauterisation of the pedicle, by means of forceps, might replace advantageously the cauterisation of the whole of the tumour, and consequently requested M. Charriere to make several forceps *porte-caustique.* That to which Dr. Amussat gives the preference is similar to the forceps used in dressing wounds, whose rounded blades form two little cylinders of about an inch and a-half in length, and from one to two lines in diameter, which increase in width as they become deeper, and are made to receive solidified caustic, or a paste made with the powdered caustic and a little alcohol. One of the extremities, longer than the other, is bent like a hook, so as to prevent the hemorrhoid from slipping when seized, and at the same time, as the furrow exists on its internal surface, to cauterise the tumour. This instrument may easily be made with an ordinary dissecting forceps, by cutting off the extremity of one blade, bending the other at right angles, and making a furrow on its inner surface.

Having been present about a fortnight ago at an operation performed by Dr. Amussat, I noted down the details of the case, in the conviction that the description of the operation, and the enumeration of the means employed to prevent the development of consecutive accidents, would prove useful and interesting.

Case.—M. D., ætat. 60; strong constitution; was never ill previous to 1840, at which period he experienced, for the first time, an unpleasant sensation in the rectum, accompanied by slight hemorrhage. Since then the same symptoms have occurred very frequently, especially when, from stress of business, he fatigued himself more than usual. The tumour was so large that M. D. thought he was affected with prolapsus ani, and, to keep it reduced, he wore a species of bandage of his own invention, which rendered progression extremely difficult. At length his sufferings became so acute that he resolved to consult a surgeon, and at the recommendation of his medical attendant, Dr. Pouget, Dr. Amussat was called in, who recognised the existence of two internal hemorrhoidal tumours, as the cause of the pain experienced by M. D., and of the prolapsus ani, which inconvenienced him so much. The operation appearing indispensable, it was fixed for the 16th July, and the day before a gentle purgative and total abstinence from food was prescribed.

July 16.—Accompanied by the Messrs. Amussat, I called on M. D., whom we found very favourably disposed. An enema having been administered, in order to empty the rectum should it contain any fœcal matter, and the patient having strained, as if at stool, the two hemorrhoids became very apparent. They were about the size of a large nut, but somewhat flatter, and were placed on each side of the gut, not very far from the anal orifice, and presented two corresponding external tumours. The patient was then placed on the right side, and Dr. Amussat seized with the forceps *porte-caustique,* the left hemorrhoid, which was the largest and the most painful: after a minute and a half, without letting it go, he opened it throughout its whole extent; evacuated the blood contained in its interior, and cauterised it with the solidified caustic: the latter part of the operation lasted only half a minute. Two injections were next made, in order to remove any particle of the caustic which might have remained, and which might cauterise the surrounding parts; and the patient was placed in a hip-bath previously prepared, in which he remained several hours, without experiencing any violent pain. The night was passed favourably; no fever; and the next morning the pain was not very intense; the cauterised hemorrhoid was flattened, blackish, similar to an eschar, and the two edges of the incision were visible. Very little food, and an astringent tisanne, were prescribed, in order to prevent any stools taking place, as they might cause the hemorrhoid to separate prematurely, and be followed by hemorrhage. For six days, this treatment—frequent hip-baths, injections, cataplasms on the anus, and a little broth only—was strictly adhered to; when, on the seventh day, the hemorrhoid separated without producing the least pain, after a very small stool.

On the 24th, I called again on M. D.; he was then quite well, and, instead of the hemorrhoid, there was a small linear cicatrix, about a line and a half or two lines in length, surrounded by a reddish areola and slight suppuration. The right tumour appeared to have decreased, and to be shrivelled. During the week which preceded the separation of the hemorrhoid, M. D. had several small and nearly liquid stools, produced by the enemas, but without disturbing in the least the process of cicatrisation. A few days after the operation, the patient complained of a severe pain in the left external hemorrhoid, and a small opening was made with a lancet, and a red granular substance escaped, with instantaneous relief. Dr. Amussat intends at a future time to cauterise the right hemorrhoid.

Fissure of the Anus.—The two following cases, which occurred in the wards of Professor Trousseau, indicate the mode of treatment adopted by this distinguished practitioner, and prove that this painful affection may be cured without having recourse to an operation.

Case 1.—P. G., ætat. 21, sempstress, was received at Necker Hospital on the 22nd of January, 1845. Immediately after her accouchement, which took place about nine months before, she was affected with acute pain on going to stool, which has continued to the present time; the pain is intense during the evacuation, and increases gradually, so as to attain its maximum in a quarter of an hour after, continuing thus half an hour, when it decreases, and, finally, in about an hour, disappears; the patient shudders at the very idea of going to stool, and remains sometimes three or four days without an evacuation; this, as may be supposed, renders the pain more acute, and each motion is followed by hemorrhage. On examination, a fissure was discovered, posteriorly, extending inwards from six to nine lines; introduction of the finger was excessively painful.

R. Extr. Ratanhæ ℨivss, Aq. puræ ℔j; ft. Enema, bis in die injiciend.

24.—The pain lasted after the injection only a quarter of an hour; and decreased daily, so that, on the 27th, it ceased after five minutes.

29.—Pain still slight, lasting only five minutes; a little blood was passed with the feces. Enema cum extr. ratanh. statim.

31.—Pain and quantity of blood on going to stool more considerable than on the preceding days. Repet. enem. bis in die.

Feb. 1.—A very painful stool, with considerable hemorrhage; pain continued for an hour, caused by a copious and abundant evacuation. Repet. enem.

2.—Pain not so long, though still as intense, and accompanied by profuse hemorrhage.

R. Gum. tragacanth ℨss, Aq. puræ ℥iv, Enema bis in die, ante enema cum ratanh. ut end.

3.—The mucilaginous injections caused somewhat less pain than the astringent; the pain, however, though not so long, is still intense. Perstet.

4.—No pain after the mucilaginous enemas; suffered twenty minutes after the first, and fifteen after the second, astringent injection; the pain, notwithstanding, was less acute; no blood. Perstet.

5.—Enemas produced the same effect as yesterday. Continue enema cum tragacanth, omit enema cum extr. ratanh.

7.—Pain and hemorrhage recommenced, owing to the canula having touched the fissure. Enema cum tragacanth et extr. ratanh. ut antea.

8.—Pain less. Perstet.

9.—No blood; pain considerably diminished; constipation.

R. Ol. ricin. ℥j, statim sumend. Contin. enem. cum tragacanth.

R. Extr. ratanh. ℨivss, Alcohol. rect. ℈j, Aq. pura, ℔j. Enema bis in die ut antea.

10.—Oil produced ten stools, without any pain; none after the injections. The patient, before entering the hospital, had been affected twice with diarrhœa, and then the pains were more intense. Perstet. Pilul. Anderson, No. 1, h. s. sumend.

11.—No pain after the stools. Perstet.

12.—An examination took place, without an injection, and without causing pain; fœces not so firm. Perstet. Under this treatment the amelioration continued, and the patient left the hospital quite well on the 27th of February.

Academy of Medicine; Sitting of the 22nd July. (concluded)—*Discussion on Typhoid Fever.*—Dr. Renauldin: Dr. Gaultier de Claubry stated that typhus never relapsed. Dr. Gaultier de Claubry (interrupting): I did not say that typhus never relapsed, as I myself had it twice, and I have seen other instances; but this is not common, nor does it invalidate the general rule I indicated; as to typhoid fever, Professor Chomel, Dr. Louis, and other practitioners, have never met with a relapse. Dr. Renauldin: The general rule, as far as regards typhus during epidemics, meets with numerous exceptions. I had this disease twice, and I lost two friends, who, after recovering from a first attack, fell victims to a second. I have likewise seen upwards of fifteen relapses during epidemics. Dr. Collineau stated that he had, in order to endeavour to conciliate the different opinions as to the identity

or non-identity of typhoid fever and typhus, examined the numerous documents sent to the Academy, but it would appear without any benefit, since the learned academician still remained in doubt. Dr. Castel read a long discourse, of which the following is a *resumé*:—Contagion is subordinate to the nature of the emanations produced by the sick body. The species of fever being the same, the emanations vary according to the country, the climate, the seasons, and also according to the stage of the fever. The influence of these emanations is more or less active, according to the age, the idiosyncrasy, and the proneness of the individual to receive them. Whence it results—1. That a fever which is not contagious to-day, may become so to-morrow; 2. That while the fever lasts, the contagious principle may arise and develop itself spontaneously; 3. That it may be communicated to part only of the surrounding persons. Contagion cannot exist without infection, whereas the latter may take place independently of the former. Dr. Rochoux: As to typhoid fever, I have said all I have to say; I will, therefore, briefly reply to some remarks that have been made. Professor Gerdy spoke of infection and contagion, but this will find its place in the discussion on the plague. Dr. Dubois d'Amiens accused me of having treated too harshly the works published on the Pathology of Fevers previous to 1804, but I defy him to note a single work on the subject previous to that of Prost, and he will not succeed better than Drs. Ferrus and Merat in his assertions. Our colleague, forgetful of the precept of Aristotle's logic, that of two contradictory opinions one is necessarily true, the other necessarily false; condemns equally Dr. Gaultier de Claubry's and my own opinions. It may, therefore, be concluded the learned secretary has condemned an opinion founded on truth, whether it be that expressed by Dr. Gaultier de Claubry or that by me. What Dr. Louis accuses me of having said of Dr. Bretonneau is not in the *Comptes Rendus*, and, therefore, his critical remarks may be considered as if they had not been made. Dr. Castel says that I see nought but absolute things, but this is not my fault, but the fault of common sense and sound philosophy. This Epicurean philosophy is founded on a principle as evident as a principle can be—that the atom is endowed with activity. Dr. Merat remarked that it was the first time Dr. Rochoux had spoken of works anterior to 1804, but it was not on this that an answer was made, but on what passed in the wards of the various clinical professors. Dr. Gaultier de Claubry stated that in reality Dr. Rochoux was his sole opponent, and therefore it was only requisite to answer him. The objections made by our honourable colleague were founded—*on the delirium*, but on consulting the different works published on typhoid fever, especially those of Professor Chomel and Dr. Louis, it is evident there is no species of delirium peculiar to this affection, and consequently it is impossible to establish a distinction between it and that observed in typhus. *On the eruption*: from clinical facts observed by me and stated in various works, I am convinced that the eruption in typhoid fever does not differ in the least from that of typhus. *On the pathology*: it is true, that previous to 1811 it was but little attended to; since then, however, the researches that have been made are as complete as possible, and Professor Cruveilhier, who performed numerous autopsies of persons who had died from typhus from 1810 to 1814, affirms that he discovered lesions identical to those attributed to typhoid fever; therefore, as the lesions, the symptoms, and the mode of development are the same, I do not see how the identity of the two affections can be doubted. *On contagion*, I have nothing more to add here than that my convictions are precisely the same now as those I have already expressed. Dr. Honoré will never admit that typhoid fever is contagious until a case is shown to him, in which it can be said *this is where the disease was contracted*. Contagion is, therefore, an exception, and cannot be given as a general rule. Dr. Desportes: What I have to say is very plain; it is only relative to the contagion of typhoid fever. Facts have been quoted as instances of contagion in this disease, but I do not think them admissible; for in medicine they can only be valued according to the commentary which accompanies them, and which is always in proportion to the advancement of science. Let us, therefore, examine what our medical knowledge will furnish in interpreting the facts cited by Dr. Gaultier de Claubry, by a physician practising on the banks of the Loire, on whose memoir Dr. Bricheteau lately presented a report, and by various other practitioners. The expression, *nothing is so brutal as fact*, so often employed, ought to be abandoned, for a fact is not so, even when at first sight it appears most unexpected and exceptional; it presents itself as a fact, because it is described with all the details which our medical knowledge permits, and consequently raises doubts and reflections, even with all the circumspection and care which the most circumspect, the exactest, and the best governed science possesses. But to return: the facts given as proofs of contagion may be classed under three heads—1. An individual is attacked with typhoid fever, and the persons who live with or approach him are also soon after affected. Now, let me ask, why must this be considered as a case of contagion? Is not a mother nursing her sick child—is not a child who approaches her nurse while suffering from this affection, exposed to the same hygienic influences as the sick person? And are we justified in attributing the propagation of the disease to contagion? Assuredly not. Again, when anyone attends a patient for whom he is deeply interested, numerous changes take place in his economy; the long watching, the fatigue wear him out; he is sad and anxious, and all the usual precautions in diet are omitted or forgotten. Are these causes not sufficient to produce a disease of a typhoid character? 2. One or more individuals come from a distance to a house in which typhoid fever reigns, and are themselves attacked by the disease. This is supposed to be a case of contagion. But what has happened? They have come to a house in which the actual hygienic conditions are adapted to produce a peculiar disease—*typhoid fever*—where they are sad, sit up late, and are therefore fatigued by attendance on the patient; where they do not follow a proper diet—causes of themselves sufficient to give rise to a typhoid affection. 3. Finally, there are some persons who, after visiting a patient sick of typhoid fever, on their return home (often at some distance) are attacked with the disease, and communicate it to those who attend them. The preceding remarks are in a great measure applicable here, and explain the production of the disease, without there being any necessity to have recourse to contagion. Some practitioners admit the existence of diseases which, after having been transmitted once or twice, lose their contagious principle; this may be accorded: but in return, it must be admitted that in certain places, very limited it is true, almost epidemic, morbific conditions may exist, and attack only a few individuals. What other interpretation can be given to facts of daily observation, such as the following:—Towards the close of the year 1841 a lady was attacked with *gastric fever*, complicated with pulmonary catarrh; a fortnight after her maid was affected with a dangerous lobular pneumonia, with *gastric disturbance*, which was cured with difficulty. While still sick, the son of her mistress was seized with cynanche and fever, complicated by *gastric disturbance*, and a roseate eruption on the neck and chest, which soon disappeared; finally, the man servant was attacked in his turn by intense *gastric fever*, abundant sweatings, and, towards its close, slight intermittents. Would any one see here an instance of contagion? Certainly not. Yet all the diseases presented a common character—an affection of the stomach and the mucous membranes. You refuse to admit contagion in these cases, in every respect similar to those quoted in its favour. You deny it, because you call it typhoid fever. No more contagion exists in this instance than in those you have recorded; otherwise, all would be contagious, for every disease, under similar circumstances, might thus be propagated. But it is stated that the body of the patient affected with typhoid fever exhales contagious miasmata—a sort of seed reproducing the disease. A reply is here necessary. In the first place, it is not indispensable that an individual should be sick to give rise to serious diseases. When at any public rejoicings a large crowd assembles on any of the public places, it constantly happens that many of the persons who were present, hustled and oppressed by the heat and disagreeable smells around them, who were fatigued, sleepy, &c., fall sick—some of typhoid fever. What practitioner has not had opportunities of witnessing similar cases? Here what occurs is quite analogous, though not so strongly manifested, to what is observed in a closed room, where a great number of healthy individuals, or in a hospital, where too many patients affected with typhoid fever or other diseases are collected. Those who enter these places suffer; yet typhoid affections are not the only ones produced, admitting such to be possible, by the miasmata, and at all events it cannot be denied that they have but a feeble influence over the diseases propagated. It is notwithstanding positively affirmed that miasmata are exhaled by typhoid fever, and that these emanations are determining causes; but those who maintain this opinion show us the mask only—why not the object itself? This is impossible, consequently they are obliged to be content with mere words. Now this is what I consider cannot be granted. Be this as it may, I do not intend explaining why I consider the diseases are produced by infection rather than imaginary miasmata. The opinion that the bodies of typhoid patients incessantly generate specific miasmata by which the disease is propagated has already been answered, but will be refuted still better by what follows. What if the bodies possess such power, how comes it that it is not communicated when a person whose finger, cut or scratched, is wet with the purulent, bloody, or other fluids, while dressing a typhoid patient affected with an abscess or ulceration, or while performing an autopsy? The result here is a more or less intense phlegmasia of the venous, lymphatic, or nervous systems. The disease, though so contagious, has not a specific miasma to introduce into the system, by a highly absorbent surface, a wound. Again, this generating focus of specific contagious miasmata—the body of a typhoid patient—becomes suddenly without action on surrounding individuals if washed with a little water. This fact cannot be denied. But how is it that the production of the miasma is weakened, or put a stop to, by simple ablution of the skin? Would it not be far more reasonable to abandon the idea of a contagious miasma, and to admit the morbific influence exercised by a number of healthy or sick persons in an open or covered space on those exposed to it? This opinion seems to me to be confirmed on considering that in diseases really contagious, such as variola, rubeola, plague, &c., the bodies may be washed as much as possible, and yet they remain contagious; indeed, it may happen, as I think I have remarked, that the manifestation of the contagious principle is more powerful according as the skin is better cleansed from the foreign bodies on its surface. I therefore consider lotions with water, or soap and water, as a good means of ascertaining if a disease really is or is not contagious, as I do not know any contagious affection which has not been propagated notwithstanding frequent washing; typhoid fever cannot therefore be placed in this category. Finally, if really dothinenteritis be contagious, the facts quoted cannot, when attentively examined, be considered as undeniable instances.

GARLAND DE BEAUMONT, D.M.P., B.L., & S., &c.,
Honorary Physician to the Spanish Embassy.

PROGRESS OF GERMAN MEDICAL SCIENCE.

By SIGISMUND SUTRO, M.D.

Two cases of softening of the Skull.—The first was that of the child of scrofulous parents, in which, immediately after birth, the bones of the skull were quite natural. Three weeks afterwards, the author was called to attend the child in an attack of suffocation. The child sometimes ceased breathing entirely when lying on its back. The occiput was elongated, and its whole extent seemed soft and quite thin. If the occipital protuberance was pressed, breathing immediately stopped, and continued short and difficult for a time. The margins of the parietal bones seemed also softened, and were at least 9''' from each other. From the middle of the frontal bone as far as the glabella, an equally wide furrow was visible. The fontanelles were elastic and soft, and the parietal bones movable and loose. The author ordered for the mother—℞. Phosphat. sod., Conch. præpar., Sacchar. āā ʒj,

a teaspoonful four times a day, and a small quantity of the same to be given the child three times a day. The child afterwards took an equal quantity of phosphate of lime and sugar. The second child was perfectly healthy, and only occasionally seen by the author. The treatment was nearly the same. (*Dr. Boecker in Raderhein und Westph. Corresp. Blatt.*)

On the entire Treatment of Gonorrhœa by Injections of Nitrate of Silver.—Demulcents, with nitre, camphor, cubebs, copaiva, astringents, and iron, still play the principal part in the treatment of gonorrhœa, and allow the disease to proceed unchecked for weeks and months. Since Girtanner, who used injections of copper, lead, and zinc in chronic cases, maintained that gonorrhœa could be cured by local means alone, several attempts have been made to dispense with all internal treatment. Girtanner himself often injected opium and a solution of lead, occasionally, also, a weak solution of caustic potash; but the occurrence of chordee, epididymitis, and neuralgia of the testicles, excited a dread of local treatment. The irritating injections were left off, and milder liquids resorted to, such as aqua chlorinata, &c. In addition to this, the belief that early injections caused stricture, discouraged the attempts at local treatment. Internal remedies were then recommended, and large doses of cubebs and copaiba used. Local astringent baths were also tried, but soon abandoned from fear of metastasis. During the last ten years, many surgeons have tried to treat recent gonorrhœa locally. Ricord cauterised the whole urethra with lunar caustic, by means of Lallemand's instrument; and Carmichael injected, twice a day, a solution of ten grains of nitrate of silver in one ounce of water. Retention of urine, &c., which often ensued, deterred many from attempting this treatment. Acton tried a milder and more careful plan. He maintained that a recent gonorrhœa may be cut short by making twelve injections (of one grain of nitrate of silver to an ounce of water) during the first forty-eight hours, and then discontinuing the injections, and administering large doses of cubebs and copaiva. Acton never observed stricture or orchitis follow this mode of treatment. According to the author, acute as well as chronic gonorrhœa may be safely cured within three or four days, without any other remedy than injections of nitrate of silver. The following are the author's conclusions:—1. Injections are most proper for those persons who have before suffered from gonorrhœa. 2. Recent inflammatory gonorrhœas, with a tendency to chordee, &c., contra-indicate the injections, till the inflammatory symptoms are removed. 3. Already existing chordee, epididymitis, &c., also contra-indicate the injections. 4. Whether the gonorrhœa proceeds from infection, masturbation, or other causes, makes no alteration in the treatment; hemorrhage caused by inflammation of the prostate or Cowper's glands, prevents this mode of treatment. 5. The strength of the injections must depend on the individual; in general, a quarter of a grain to an ounce of water is sufficiently strong for the first injection, but it should be gradually increased in strength till strong reaction appears, known by a reddish discharge and the appearance of blood from the urethra; two or three injections more will then be sufficient to effect the cure. 6. In general, an injection is to be made every three hours, but less often if the reaction should be very strong; they ought always to be made after discharging the urine. 7. It is useless to employ internal remedies after the injections. 8. It is also useless for the patient to alter his diet during the cure; he can eat as usual, and has only to avoid spirituous liquors and too active exercise. 9. The author never observed chordee, prostatitis, &c., follow this treatment, though he often employed it by way of experiment in class with active inflammatory symptoms. 10. An inflammatory state of the prostate or of Cowper's glands must always be supposed, if the patient feels pain or particular sensibility in that portion of the urethra which takes its course in the perinæum. The author also mentions a sort of abdominal gonorrhœa, which he observed in a young man of thirty-two years, which resisted all treatment for years, and at last disappeared spontaneously, when the patient changed his former sedentary mode of living. The author believes that, in case the above injections are either contra-indicated or found useless, no other internal remedies should be employed except copaiva, cubebs, and, perhaps, linseed tea; and he believes that nitre, camphor, astringents, tonics, iron, &c., ought to be laid aside. Inflammatory symptoms are to be treated by the usual antiphlogistic means. The liquid ought to be retained in the urethra from one to two minutes. The author concludes by detailing six obstinate cases of gonorrhœa, each of which was cured within four days by the above treatment. (*Dr. Von Gutteeit of Ord, in Schmidt's Tahrbücher.*)

Acute Rheumatism rapidly ending in Apoplexy.—A clergyman, ætat. 59, usually healthy, was taken ill, after having suffered from chills for a few weeks, on the 27th February, 1842, with symptoms of rheumatic fever, and painful swelling of several joints. He did not seek medical aid till the 1st of March; he was then ordered a decoction of taraxacum, with Glauber's salts, nitre, tartar emetic, and syrup of manna, without relieving the pain or swelling. The bowels at first were only opened once, but became relaxed after a repetition of the medicine. The pains now diminished, and on the 4th the patient felt still more relieved, and was merry, but during the following night delirium supervened, and the next morning he could not speak distinctly. He only became conscious for a short time, and was able to stammer a few words. The pulse was very rapid and peculiarly tremulous, the skin hot and dry. Notwithstanding leeches to the head, mustard poultices to legs and arms, and arnica given internally, he died at 7 p.m. Rheumatic metastasis is rarer, and more rapidly fatal, when it attacks the head, than when the heart or pericardium is affected. —(*Dr. Camerer, of Langenau, in Würtemb. Correspond. bl.*)

Amaurotic Amblyopia following the use of Morrison's Pills.—A lieutenant of artillery noticed one morning considerable decrease of visual power, and within two days he could not read the largest print, nor recognise any face. No cause could be given for this affection, except cold. There was no fever, nor loss of appetite, but some heaviness in the head was complained of. The pupils were a little dilated, and the iris acted slowly. A diaphoretic treatment was commenced, but without success, and the disorder seemed to increase. On the third day, when the patient was desired to take a purgative, he asked whether he might not take Morrison's pills, which he had begun using three days before his illness in consequence of frequent costiveness. He mentioned at the same time that the pills had not yet operated, though he had taken large quantities. This statement immediately gave rise to the idea, that the drastics and narcotics, particularly the stramonium, contained in these pills might have caused the affection. An emetic was, therefore, immediately administered, and afterwards camphor, with morphia, and strong coffee, without milk, was frequently taken. A blister was applied behind both ears, and infus. senn. compos. given to remove the obstruction. By this treatment the affection was completely removed within three days.—(*Dr. Stumpf, in Preuss. Vereins. Zeit.* No. 23, 1844.)

Amaurosis following Syphilis, cured by Pollini's Decoction.—K., ætat. 30, of plethoric constitution, none of whose family ever suffered from complaints of the eye, perceived in February, 1842, for the first time, a black point before the right eye, whenever he directed it towards a bright object. The eye appearing also very sensitive, ten leeches were applied behind the right ear, and great care in diet recommended. The complaint, however, became worse, and after some days was attended with congestion of the brain. Cooling and opening medicines were administered, and leeches applied to the anus (hemorrhoids being suspected), with venesection to the extent of sixteen ounces. No benefit followed, and another physician who was called in directed the extract of hyoscyamus niger, with acetate of morphia, to be rubbed into the eyelids, to counteract the great sensibility of the organ. This treatment produced no effect, and the patient used no remedies for several months. The black point increased, and dark lines extending from it became very numerous, and united into a small net. In January, 1843, the patient came under the author's care, who observed the following symptoms:—Constant flow of tears, increased brilliancy of the bulb, a little photophobia, and at the same time an increased activity of the pupil, which was somewhat oval. No other changes could be perceived. After a derivative treatment of several weeks had produced no effect, he observed an eruption on the inner surface of the right wrist. The author then discovered that the patient had suffered from chancres on the glans penis four years ago, which was soon healed by a red ointment. He had observed the eruption periodically for about two years, particularly in autumn and spring. It consisted in small reddish-brown crusts, which dried and left copper-coloured spots behind. Similar crusts were found at the inside of the elbow and knee-joint of the right side. The author ordered the decoction of nut-shells, sarsaparilla, bark, and antimony, as recommended by Rust, a pound of which the patient drank daily for twenty-one days. At the same time he took exercise in his room, and then went to bed for two hours to promote perspiration. The eye, to which cold lotions were applied, improved considerably; and when the patient, after having omitted it for a week, had drank the decoction again for twelve days the black point had disappeared, and only the lines remained, which disappeared spontaneously in about five months. The patient now writes and reads a great deal, without any sign of relapse.—(*Dr. Cruzizat, Oberreissenberg in Oesterr. Wochenschrift.*)

Strange Suicide.—N., ætat. 71, loaded a pistol with an open penknife, and shot it into his mouth. He died in four hours. The post-mortem examination showed that the knife had not penetrated the skull, but had made a rent of an inch long in the tongue, and of half an inch in the soft palate. Death was apparently caused by concussion of the brain, with extravasation of blood under the pia mater.—(*Dr. Fritz of Vienna, ibidem.*)

On the Frequency of Alkaline Urine in Healthy Persons.—It was formerly assumed that recent urine displays an acid reaction, unless it has lost its acidity by the previous internal use of alkalies. On this account alkaline urine was unhealthy. But Wohler showed, that not only after the use of neutral salts with vegetable acids, but even after (vegetable) acid salts, the urine was frequently alkalinescent. He assumes that these latter salts are transformed into carbonates within the body, and are brought into the urine as such, rendering it alkaline, and causing also the precipitation of the phosphates, which are only soluble in an excess of acid. Besides, he observed, that after taking abundance of fruit, particularly sweet fruits, such as cherries, or strawberries, the urine became often alkaline. Wohler concluded from the above, that salts with vegetable acids and fruit are particularly to be recommended in the uric acid diathesis. Practice has confirmed the truth of this recommendation. The author found that, even after taking from one to two tablespoonfuls of apple juice, the urine became alkaline within half an hour to an hour and a half. The effervescence of alkaline urine, observed by Wohler, after taking great quantities of fruit, has been remarked by the author after the above small quantity of apple-juice, but more decidedly after about twelve baked plums. As precautions for the experiments, the bladder ought to be emptied before eating the fruit, and only little water should be taken in order that the alkaline reaction may appear prominently. Fruit exerts, of course, the same influence on the urine during illness as in a natural state, so that turbid urine must sometimes be rather ascribed to diet than to abnormal causes. The above facts must influence considerably the diagnosis of several diseases, as—1. *Simple chronic nephritis*, its chief and sometimes only symptom is maintained to be: less acid, or alkaline urine, with a sediment of phosphates (particularly phosphate of lime and triple phosphate) 2. In *spinal diseases* the alkaline urine might also be occasioned by fruit, at least the author found no alkalinity in caries of the vertebræ, and whenever alkaline urine is met with in spinal diseases, it may be occasioned by a secondary disorder of the urinary mucous membrane, or by decomposition of the urine during the period it remains in the paralysed bladder. If vesical disease combines with the spinal, the urine is found alkaline. 3. *Morbus Brightii.*—The property of alkaline urine to become turbid when heated may easily give it the appearance of containing albumen, particularly since the precipitate of the phosphates floats at first in the form of little clouds in the

vessel, like coagula of albumen. They can easily be distinguished from albumen by their solubility in acids (particularly nitric acid), by their being deposited long before boiling takes place, and by their much more rapid precipitation than coagulated albumen, consequent on their greater density.—(*Dr. Krukenberg of Braunschweig in Henle's u. Pfeufer's Zeitschr.*)

Large Doses of Tartar Emetic in Intermittent Fever.—A tertian intermittent fever was suppressed by quinquina, quassia, quinine with rad. bellad. and mag. bismuth. with clysters of quinquina; but it soon reappeared in the form of febris intermittens octava, when large doses of quinquina were given without any effect. The patient was a drunkard; the fever appeared with symptoms of peculiar cerebral and nervous irritation, and the mephitic vapours had exerted a paralytic effect on the body. These circumstances induced the author to order daily six grains of tartar emetic, and to increase the doses by two grains every day, so that at last four drachms were given daily, till the fever disappeared. These enormous doses produced no unpleasant effects.—(*Dr. Teittelez, of Prag., in Oestrr. Wochenschrift.*)

A Scrofulous (?) Disease treated by Bichloride of Mercury.—A girl, of fourteen, was affected with a disease which the author calls scrofula, but which was very peculiar. The mesenteric glands could be felt through the abdominal walls; the glands of the throat were also enlarged. The skin was covered with prurigo. For two years the head had inclined towards the right side. The region between the second and fourth cervical vertebræ was very painful on pressure. The vertebræ seemed swollen, and touching them caused not only local pain, but violent headache; the headache was lancinating, particularly at the parietal eminences and in the frontal region. At the latter spot such an exuberance and matting of the hair appeared, that it was not unlike a plica polonica, and quantities of hair were necessarily removed. The pain was most excruciating in these spots, and near them large, movable, painless tumours were perceived; digestion was irregular; the perspiration fetid. The parents were perfectly healthy, and the patient was thought to have been infected by the nurse. All the usual remedies in scrofula were tried without benefit, but a cure was effected by the bichloride of mercury, which the author ordered in doses of one-twentieth of a grain per diem for the first eight days, the quantity being afterwards doubled.—(*Dr. Teittelles, ibid.*)

Poisoning by Carbonate of Lead.—A strong servant, ætat. 20, was recommended to take chalk on account of acidity and heartburn. He took by mistake a piece of Kremitz colour, and ate about five or six drachms of it. After a few hours he complained of violent burning pains in the stomach, with vomiting. Twenty-four hours after, when the author first saw him, he suffered from violent pain, particularly in the pit of the stomach and the umbilical region. His face was red and swollen, his eyes shining and prominent; his tongue and mouth dry and very red; abdomen distended and extremely sensitive to superficial pressure, whilst stronger pressure alleviated the pain; great thirst; bowels constipated. The author ordered six drachms of sulphate of magnesia dissolved in water, with one scruple of tinct. opii simpl. to be taken at once, and larger doses of the same salt to be repeated with an oily emulsion, by which means the patient soon recovered.—(*Dr. Scubert, of Dramsburg, in Casper's Wochenschrift.*)

Astonishing Effect of Arsenic.—The disease which led the author to the choice of the above remedy was scirrhus (?) uteri passing into carcinoma. After common remedies had been tried without benefit, the author administered one-twentieth of a grain of Fowler's solution, and augmented the dose after a few days, since it was followed by no ill effects. He afterwards prescribed the following:—℞. Arsen. superjodat., gr. ij; Aq. destill., ℥vj; to take fifteen drops morning and evening, and to increase three drops every other day. This treatment was continued for several months. The flying pains soon ceased, the pressure below the ossa pubis disappeared; the os uteri lost its cauliflower appearance, the stinking discharge ceased, and when the patient had taken twenty-two grains of arsenic, she was perfectly healthy, and has been so for the last three years.—(*Dr. Teittelez, of Prag., in Osterr. in Wochenschrift.*)

Melancholia Intermittens Tertiana cured by Fowler's Arsenical Solution.—This complaint was first treated by laxative medicines, and afterwards by large doses of quinine, combined with belladonna, trisnitrate of bismuth, acetate of morphia, and bark in different forms. The general health seemed to improve, but the melancholic state remained still of the tertian type. The author administered ten drops of Fowler's solution twice a-day, and increased the dose two drops from time to time. The remedy produced an amendment, and was continued, though a pause seemed to occur in the cure. Five months after the patient was perfectly well, blooming, and cheerful. The author concludes from the above, that in its first effect arsenic alters the nervous functions, that subsequently, if continued for some time, it affects nutrition, and at last alters the whole system. In obstinate chronic nervous disorders, its peculiar effect is only perceived after a long time.—(*Ibid, ibidem.*)

Cochineal a Specific in Hooping-Cough.—During an epidemic in the winter of 1844, the author saw the violence of hooping-cough checked, the paroxysms diminished, and its duration shortened, by the use of cochineal. In the catarrhal stage he administered an emetic, and then prescribed the following mixture, which was to be taken within two days:—℞. Cochineal, gr. iv; Sal. tartar, gr. viij; Aq. fervid., ℥ iss; Syrup. spl., ℥ j. It had no effect in the cough accompanying measles.—(*Dr. Bennewitz, in Casper's Wochenschrift.*)

PROGRESS OF ENGLISH, ITALIAN, AND AMERICAN MEDICAL SCIENCE.

[The following are the principal articles of interest to our readers in three numbers of the *Lancet.*]

The Remedial Efficacy of Ox-gall.—Dr. Allnatt confirms the testimony rendered by Dr. Clay, as to the efficacy of ox-gall in cases of constipation; he has given it both in the form of pill and of enema. When given in combination with opium, it neutralises its constipating, without influencing its sedative action. Five or eight grains of the inspissated ox-gall are sufficient to neutralise one grain of opium.

Poisoning by Arsenic.—Mr. Woodcock mentions a case of poisoning by arsenic, in which life was apparently saved by the use of the hydrated tritoxide of iron, and by inducing and keeping up early and free vomiting.

Disease of the Femur.—Mr. Cumming narrates an interesting case which occurred in the practice of Mr. Luke, in the London Hospital. The patient was a female, twenty years of age, a barmaid. On admission there was an uniform swelling around the left knee, with considerable thickening and some effusion. The patient's health was bad, and she laboured under anemia. The swelling was of about four months' duration. As it continued to increase in size, a grooved needle was introduced, and about two or three ounces of a clear orange-coloured fluid escaped. In the course of a week the tumour was again tapped with a small trocar, and five ounces of fluid were withdrawn, no more escaping readily, although there was evidently a much larger quantity. The fluid coagulated spontaneously, and on being left at rest, it formed a soft, semi-transparent clot, coloured by blood globules, the remaining part separated as serum. As the swelling was rapidly increasing in size, and the patient's health becoming worse, amputation was proposed, but her consent could not be obtained. A bread-and-water poultice giving relief, it was applied over the swelling. The increase in size was very great; it seemed to have burst the bounds of the bursa, and extended half-way up the thigh. A number of dilated veins were first noticed on the outer side, and then a red-streaked appearance, in patches resembling somewhat the appearance so often observed in medullary disease; the vessels were, however, in this case, much larger. The parietes were evidently shining all over the surface under the distension; the limb was laid rather upon the outer side of the knee, with the foot and leg somewhat everted, very œdematous, and feeling numb. The puncture was repeated once or twice, but as the fluid would not run out, little relief was afforded. A few days afterwards, the integuments gave way, and a very large quantity of fluid escaped, the tumour collapsing in consequence. The patient died the same night. The body was examined two days afterwards. Nearly the whole thigh, up to the junction of the upper and middle thirds, was hollowed into a large cavity or cyst, having the triceps situated anteriorly, extremely flattened and attenuated; it extended round and behind the femur, pushing back the muscles at the posterior part. Over the inner surface of the cavity thus formed of the muscles and surrounding parts, there was an effusion of soft lymph; one pint of fluid still remained in the cyst. The lower end of the femur presented the following appearance:—The inner condyle, with the lower part of the bone attached to it, was destroyed for three or four inches up from the cartilage covering the inner condyle, the destruction passing also slightly outside the median line, and anteriorly more externally, where it was partially destroyed from the cartilage of the outer condyle. It presented a complete excavation, no bony matter being left. The inner cartilage was entire, although it had lost the whole of its osseous attachment, being still connected to the synovial membrane. The outer cartilage was also entire. The attachment of one crucial ligament was destroyed, a small healthy scale of bone being separated with it; the synovial membrane was perfectly healthy. In the situation of the inner condyle, and attached to the posterior part of the inner cartilage and surrounding parts, but lying loose for the most part, and unconnected, and passing over the anterior part of the femur, was a mass which would have about filled a pint measure. Its structure was fibrinous, mixed with coagula; the fibrinous part was tolerably consistent, and of the usual buff colour; in the interior of the mass were some irregularly formed cells, or small cysts, containing fluid. The mass appeared to have laid over, and in the hollow of the bone, but had no attachment at all to it. In the hollow was a small quantity of unattached flaky caseous matter, soft, and resembling medulla. The section of the mass presented no appearance of medullary deposit, nor of the usual septa, but that of a fibrinous mass of a cellular character, with a few irregular cysts and coagula. The bone being sawn longitudinally, was found quite healthy down to the very margin of the excavated portion, with no appearance of medullary deposit. The periosteum had deposited some osseous matter, apparently from the irritation it had been exposed to from the fluid passing over it. The glands in the groin were not enlarged, and all the thoracic and abdominal organs were sound, though anemic in appearance. Mr. Cumming does not consider the disease in this case to be of a malignant nature, but looks upon it as a mass of fibrinous structure, having, from some unknown cause, the power of forming cysts communicated to it, or one cyst with the power of developing others, which increased to a large size, and caused great irritation. He thinks it probable that it originated in the cartilage and its vicinity. The abnormal growth and vicinal structures should have been examined microscopically.

Anemia and Hysteria.—Mr. Pearce narrates a case of long-standing anemia, which was suddenly complicated with violent hysteria, and terminated fatally. The case appears to be involved in great obscurity.

Case of Malformation.—Mr. Robinson describes a case of malformatian which presented itself at the clinique of Sir John Fife. The abnormal growth consisted of a short vascular tube, projecting from the umbilicus, about three-quarters of an inch in length, and the same in circumference. From the orifice at its apex an exudation of thin fluid took place, and occasionally fœcal matter also escaped. Sir John Fife applied a ligature tightly around it, and afterwards removed the constricted portion by excision. An arterial branch required the application of a ligature. The child soon recovered.

Tracheotomy.—Mr. Chapman narrates a case of acute laryngitis, in which tracheotomy was successfully performed. The relief afforded by the operation was most marked.

Hepatic Abscess bursting into the Pericardium.—Mr. Allan gives the particulars of the post-mortem examination of a native of Bombay, who died within five hours after complaining of pain at the pit of the stomach. There were about two pints of reddish pus and serum within the pericardium, the entire of which membrane was slightly inflamed. On laying the pericardium freely open, thick yellowish-green pus was seen oozing from an aperture large enough to admit the finger, which led through the diaphragm into an abscess in the smaller lobe of the liver, capable of containing a pint of fluid. Mr. Allan thinks that the pus had been oozing into the pericardium for some hours; had there excited inflammation, and had caused death by annihilating the heart's action by pressure.

Placenta Presentation.—Mr. French was called to a lady, between the eighth and ninth month of pregnancy, in consequence of slight pains and hemorrhage. The os uteri was dilated to the size of a crown piece, with a portion of the placenta projecting over about one-third of it, and adhering to the left side. The foot and umbilical cord presented. Mr. French ruptured the membranes, when the pain and hemorrhage ceased. Strong pains and hemorrhage afterwards came on, and the child was expelled dead. The mother did well.

Poisoning by Savin.—Dr. Letheby narrates the case of a young woman, who, while between the seventh and eighth months of pregnancy, after supping over-night with her lover, was seized, about three in the morning, with violent pains in the stomach, followed by severe sickness, after which she became insensible. She was first seen by the assistant of the parish-surgeon, and afterwards by another surgeon, who found her lying upon her back, breathing laboriously and stertorously; she was foaming at the mouth; the countenance was turgid; the eyes shut, with the pupils much contracted; the limbs were also convulsed. The case was treated as puerperal convulsions: labour commenced, and was nearly completed when the patient died, twelve hours after the attack. The examination of the body showed the vessels of the surface of the brain, and the substance of that organ, much gorged with black fluid blood; this was especially noticed in the anterior part of the corpus striatum. The choroid plexus was also gorged; the ventricles were empty. The lungs were generally congested, and there were one or two red spots in the stomach, as if blood had been effused into the mucous tissue. By the chemical analysis of the contents of the stomach, an oily liquid was obtained, which presented the physical characters of oil of savin; and, from some experiments afterwards instituted by Dr. Letheby on the lower animals, it appears that savin produces symptoms and post-mortem appearances nearly identical with those presented by this unfortunate girl. The verdict returned by the coroner's inquest was, "Death from puerperal convulsions."

Pericarditis.—Dr. Taylor gives, at great length, the case of a boy, fifteen years of age, who was admitted under his care into the University College Hospital, about four days after he had been attacked with acute rheumatism. The boy had then a systolic murmur at the apex of the heart; slight pain and increased dulness on percussion. On the sixth day, a friction-sound, and systolic murmur at the base, appeared; on the seventh, there was œgophony on the left side; which was followed, on the tenth, by pleuritic friction-sound, and death on the eleventh. The examination of the body after death showed recent adhesions of the pericardium; redness and effusion of lymph on the aortic and mitral valves, and in the left auricle; slight enlargement of the heart; redness of the left pleura, with trifling exudation of recent lymph; destruction of the mucous membrane of the œsophagus; and enlargement of the solitary and agminated glands of the ileum, and also of the mesenteric glands. The next case which is narrated by Dr. Taylor is that of a medical student, who had an attack of acute rheumatism, on which pericarditis supervened on the eighth day: it was treated by venesection, cupping, leeches, and mercury, and successfully, except that there remained slight valvular disease, and some degree of hypertrophy. The patient died seven years afterwards of delirium tremens, having experienced a lightning stroke the year before his decease. The body was not examined after death. Another case described by Dr. Taylor is that of a young man, in whom the rheumatism and pericarditis were complicated with pleuro-pneumonia. The patient recovered to a certain extent under the treatment pursued, but there remained hypertrophy of the left ventricle, and disease of the mitral valve, with enlargement of the liver and spleen. This is followed by the details of a case of subacute rheumatism, attended with pericarditis, without metastasis, and followed subsequently by pleurisy and pneumonia of both sides, and by endocarditis. The patient, a female, was treated by copious bleeding, general and local, mercury, tartarised antimony, and by the application of blisters. She was discharged apparently cured. Another case of subacute rheumatism succeeds, in which recent and partial pericarditis supervened on old disease of the aortic valves. There was also nearly constant diarrhœa, to which the man was much subject, and which was kept up by the use of colchicum; the exhaustion thus produced, Dr. Taylor thinks, was mainly the cause of the fatal termination which ensued thirteen days after his admission into the hospital. The post mortem appearances were—effusion of lymph on a portion of the pericardium; old disease of the endocardium and of several valves; hypostatic pneumonia; old adhesions of the pleura; and copious serous effusion into the arachnoid cavity, with increased vascularity of the pia mater. The case of a potboy, eighteen years old, labouring under acute rheumatism for the second time, is also given. The boy had hypertrophy of the left ventricle, and disease of the mitral and aortic valves, as the remanet of the previous attack. The pericarditis which ensued in the second illness—that for which he was treated by Dr. Taylor—was speedily cured by means of bleeding and mercury; and the rapidly successful result was attributed by Dr. Taylor to the presence of adhesions from the previous inflammation.

Mr. Seton's Case.—The particulars of this unfortunate case are described by Dr. Potter, Mr. Liston's assistant. Mr. Seton was a very stout man, about twenty-eight years of age; had lived very freely, and taken little exercise for several years; his constitution was delicate and impressible, and he was easily lowered by treatment when indisposed. On the evening of the 20th of May, he received a gun-shot wound across the lower part of the abdomen, the ball entering at the upper part of the right thigh, a little above and in front of the great trochanter of the femur, and passing out about the middle of the fold of the left groin. The attendant hemorrhage was very severe, and was described as occurring per saltum; it ceased only on the occurrence of syncope, produced by great loss of blood. The patient, by appropriate treatment, recovered from the shock of the injury, and for some days his chief complaint was great pain in the right groin and lower limb, with numbness of the front of the thigh. On the seventh day after his wound, the swelling in the right groin was more marked, and was observed to pulsate synchronously with the heart's action. The swelling continuing to increase, and the pulsation becoming more evident, Mr. Seton came under Mr. Liston's hands. He then presented the appearance of a person who had lost much blood, but, although at times he suffered severe pain in the limb, there was no marked expression of anxiety in the countenance; his manner was calm and composed, and he was hopeful as to the final result. The gun-shot wounds, and the whole track of the injury, except where the aneurismal tumour existed, were going on favourably. In the right groin was found a large, oval, visibly pulsating tumour, its long diameter extending transversely from about an inch and an half on the inner side of the anterior superior spinous process of the ilium to about opposite the linea alba, and its lower margin projecting slightly over Poupart's ligament into the upper and inner part of the thigh. On handling this tumour, it appeared elastic but firm, very slightly tender, and not capable of any perceptible diminution in bulk by gradual and continued pressure. The pulsation was distinct at all parts of the swelling, and was equally evident whether the fingers were pressed directly backwards, or whether they were placed at its upper and lower margins, and pressed towards the base of the tumour, in a direction transversely to its long axis, the parts being for the time relaxed. The femoral artery was slightly covered by the swelling, and the pulsations of that vessel were with some difficulty distinguished in the upper part of the thigh, below the margin of the tumour. This appeared to depend partly on the natural obesity of the patient, and partly on a considerable degree of general swelling of this thigh. No pressure on the femoral artery or over the abdominal aorta arrested pulsation in the tumour, and pressure in the former situation was attended with severe pain. In the left groin, just above the opening of exit, was another smaller swelling, quite unconnected with and of a very different character from, the principal tumour. The skin over the smaller swelling was red, very tender, slightly pitting on pressure, hard round the margin, but yielding more in the centre, and even indistinctly fluctuating. The right testicle was enlarged to three or four times its natural size, extremely hard, and somewhat tender. The diagnosis was that the case was one of circumscribed false aneurism, the pulsation being caused by its communicating directly with a wounded artery, and not by motion transmitted from the femoral artery. It was supposed that the ball in its course had passed through the tensor vaginæ femoris, and behind the sartorius, perhaps wounding or bruising the anterior crural nerve, and dividing some branches of the external circumflex artery; that it had then passed in front of the common femoral artery (close to its commencement from the external iliac), either slightly wounding the main vessel, or dividing one of its branches near its origin; and, lastly, that it had wounded or bruised the right spermatic cord, and run over the pubes to its exit. With regard to the prognosis, it was thought that as the blood was fluid, and the pulsation continued to increase, when the sloughs separated, the hemorrhage would be renewed, and endanger the patient's life; or else that if external bleeding did not recur, that the blood would be effused upwards and laterally among the abdominal parietes, and thus, by another kind of hemorrhage, jeopardise the existence of the wounded man; and it was therefore determined to cut off the supply of blood to the tumour by an operation, as pressure was deemed to be altogether insufficient. The last question related to the kind of operation. Was it advisable to lay open the tumour, search for the wounded vessel, and tie it above and below the wounded point? In principle, this was admitted to be the first indication, and would have been clearly the proper practice, had the injury been inflicted an inch or two lower down; but practically, it was thought to be unwarrantable, under the peculiar circumstances of the case, and for the following reasons:—1. An operation of this kind, even supposing the operator able to command the circulation by pressure on the proximal side of the wounded vessel, must be attended with a loss of blood, dangerous to the patient in his present reduced state. 2. As the supply of blood to the tumour could not, in this instance, be effectually interrupted by pressure on any large arterial trunk, the hemorrhage, in searching for the wounded vessel, would probably be unusually great. 3. Supposing that the common femoral artery should be found wounded, or one of its branches divided close to the main trunk, so as to render it necessary to apply two ligatures to the common femoral itself, the chances of the recurrence of secondary hemorrhage on the separation of the ligatures would be very great, considering the frequency with which this occurs in cases where the common femoral is secured by a single ligature, and in the most favourable position that the operator can select. It was, therefore, decided that the external iliac should be secured by ligature, which was accordingly done, with the effect of arresting pulsation in the tumour. Mr. Seton, however, died a few days afterwards from peritonitis. The examination of the body after death showed that the hemorrhage proceeded from a superficial branch of the femoral.

*** Every particular of this case, as detailed by Dr. Potter, serves to convince us that Mr. Liston committed an error of judgment in ligaturing the external iliac, an operation of exceeding severity, and by no means called for, and which could not succeed ultimately, as the lower end of the injured vessel would, when the circulation was restored,

have given rise to secondary hemorrhage. The only operation that should have been performed, if, indeed, one had been indicated, and that point is extremely doubtful, was the cutting down upon, and ligaturing both ends of the wounded vessel. Common sense and the ordinary principles of surgery are in favour of this mode of proceeding, and equally against that adopted by Mr. Liston.

PUERPERAL CONVULSIONS.—Dr. Tyler Smith observes that bloodletting in plethoric states of the circulation is, in this disease, curative in its action on the spinal marrow, preventive in its action on the brain.

INFANTICIDE.—Mr. Ryan mentions several cases of labour occurring suddenly, before any assistance could be offered, so as to place the life of the child in danger. These cases are of importance in a medico-legal point of view, as regards the question of infanticide.

PUERPERAL CONVULSIONS.—Mr. Vines narrates a case in which puerperal convulsions continued after the birth of the child, but gradually subsided after the withdrawal of five pints and a half of turbid urine from the bladder.

ANEURISM OF THE FEMORAL ARTERY.—A case of aneurism of the femoral artery, in which the external iliac artery was tied, is reported from the Dreadnought hospital-ship. The patient was a man, thirty years of age, and the injury was of about seven months' duration. The operation was performed on the 18th of January last, and was followed, three days after, by an attack of acute bronchitis. The ligature came away on the nineteenth day after the operation, and the patient was discharged cured two months after.

HOMŒOPATHY.—A correspondent, in alluding to the absurdities of homœopathy, says—the usual dose of chalk and other *strong medicines* (according to the Homœopathic Pharmacopœia) is a decillionth of a grain. The way in which this minute division is arrived at, is by mixing one grain of medicine with 999 of sugar of milk; then taking one grain of the mixture, and mixing it with 999 grains more of sugar of milk, and so on for thirty times. The last thousand is *supposed* to contain a decillionth of medicine in each grain of the mixture! Or if the homœopathists wished to make a liquid, they would take a two-ounce phial, drop one drop of medicine into it, then fill it, and fill and empty it thirty times with distilled water, reserving the last *washing*, which will contain much more than a decillionth in each drop, for obvious reasons. Now, a decillion takes 61 figures for its enumeration; when brought into tons it requires 53 figures—viz., 58,000 octillions, and as the earth, at a specific gravity of three, weighs about 3,248 trillions of tons, you will find that, if you wish to mix it in bulk, it would require above 17-quintillion times the weight of our earth to mix with one grain of medicine. The following will give some idea of a quintillion:—A watch ticks five times in two seconds, or 150 times in a minute, which amounts to 78,840,000 times in a year. Yet it will take above 13,000 trillions of years to tick a quintillion-times; and this is more than *two trillion* times as long as the human race has existed; for a watch will only tick 473,040,000,000 in 6,000 years.

RETROVERSION OF THE BASE OF THE TONGUE.—Two cases of a peculiar malformation connected with the tongue are recorded by Dr. Fairbairn in *The Northern Journal of Medicine*, one of which terminated fatally. The child, which was born on the 6th of May, 1844, was large, and apparently healthy. The face presented a peculiar conformation; the superior part projected forwards, and gave a sharp appearance to the countenance; while the lower part was much depressed, the chin presenting a small flattened surface, instead of the rounded and projecting natural form; the expression of the countenance was similar to that observed in individuals who have had the body of the lower jaw excised. From a case somewhat similar, which occurred to him some years before, Dr. Fairbairn suspected that there was malformation about the throat; and, on looking into the mouth, he detected a fissure in the soft palate, which allowed the posterior nares and the vomer to be seen; the alveolar processes of the lower jaw were opposed to the back part of the hard palate above; and the tongue, which appeared short and thick at its root, lay posterior to the palate, the apex alone projecting. On dropping a little sugar and water into the mouth cautiously, it was readily swallowed; but whenever it was given in any quantity, it got into the nares and produced much irritation, with cough, and a sense of suffocation. The child died two days after, presenting, prior to death, symptoms of suffocation. An examination of the body was made after the child's decease. On opening the mouth, the posterior nares, the posterior border of the vomer, the upper wall of the pharynx, and the inferior apertures of the Eustachian tubes were readily seen; the anterior surface of the lower jaw lay posterior to the hard palate in the closed condition of the mouth; the soft palate was almost entirely deficient; the tongue was short and thick, retracted into the cavity of the pharynx, its convex dorsal surface resting upon the posterior wall of that cavity, and its base pressed upon the epiglottis and arytenoid cartilages, so as completely to obstruct the entrance of air into the larynx; the apex alone could be seen on looking into the mouth, while the jaw was forcibly depressed. Towards the apex the margins were rolled inwards and upwards, so that the anterior part presented a deep furrow superiorly. The frænum appeared to be wanting, or was so slightly developed as not to bind down the lower surface of the tongue to the usual amount. The lower jaw was nearly flattened, forming a small segment of a circle, with a greater diameter than that of which a naturally formed jaw is a segment. The following measurements were made of this jaw, and of a normally formed jaw of the same period:—Breadth between the angles, including the thickness of the bone on both sides in a natural jaw, two inches; breadth between the angles, including the thickness of the bone on both sides in the deformed jaw, two and three-eighth inches; depth of the arch, including thickness of bone in a natural jaw, one and a half inches; depth of the arch, bone not included, one and one-tenth inches; depth of the arch, including the bone in deformed jaw, three-quarters of an inch; depth of the arch, bone excluded, in deformed jaw, six-tenths of an inch. The rami were somewhat smaller and less oblique; there was no malformation of the heart or other viscus; but the thoracic viscera presented the appearances which usually occur in persons dying from asphyxia. The second case was somewhat similar, but, by great care in feeding it, the child was brought up by hand. He is now five years of age. In some judicious remarks on these cases, Dr. Fairbairn says, were a similar case ever to occur to him again, he would never hesitate to transfix the apex of the tongue, and to attach it by ligature to the gum of the lower jaw. M. Petit details a case where the frænum had been divided shortly after birth, and the child died five hours afterwards. He says, "I found it turned like a valve upon the fauces, and the point actually swallowed into the pharynx." Another case is mentioned by the same author, where the frænum had been incised two hours after birth, and where the apex of the tongue had been reversed, but not entirely swallowed. M. Petit introduced his finger and brought it back into the mouth. On the child attempting to suck, it was again swallowed. Several times he reduced it, and at last contrived a bandage to preserve it in its place; but from the carelessness of the nurse the accident recurred, and the child was suffocated during the night.

PROGRESS OF IRISH MEDICAL SCIENCE.

(FROM OUR OWN CORRESPONDENT.)

Dublin, Aug. 2.

MEATH HOSPITAL.

Death from Spasm of the Glottis; Mr. JOHN WALSH, Clinical Clerk. Thomas Reynolds, ætat. 30, a labourer, admitted into the Meath Hospital on the 4th of July, under the care of Mr. Smyly;—states that his health has always been good until eleven weeks ago, when he got a severe cold, which was followed soon after by cough and hoarseness of voice, unaccompanied by any soreness of the throat. The hoarseness gradually increased, his breathing became stridulous, and performed with difficulty, and fits of most distressing dyspnœa supervened on the slightest exertion; the feeling of suffocation he refers to the centre of the sternum. These symptoms are daily becoming worse. He never had syphilis, nor had taken mercury to his knowledge.

Present Condition.—Though a strong-looking man, his appearance is rather scrofulous; he has lost some flesh, but is not by any means emaciated. No hectic; sleeps well at night, and is not constrained to lie in any particular position; feels pain occasionally commencing at the fifth dorsal vertebra, and shooting round the side to the sternum; complains of no other pain; has a troublesome cough, with considerable glairy mucous expectoration; breathing stridulous; nearly complete aphonia; slight vascularity of the fauces, but no sign of ulceration; epiglottis seems unaffected; no dysphagia. On pressing the trachea some soreness is felt, but there is no dulness on percussion.

Physical Signs.—Right lung: percussion universally clear; vesicular murmur pure and full: no râle. Left lung—considerable flattening of the infra-clavicular region; some dulness in the same part; respiration extremely feeble in the entire upper part of the lung: tolerably full in the inferior portion. About an inch beneath the sterno-clavicular region, deep tracheal breathing is audible; no râle discovered. Heart-impulse and sounds normal: no murmur heard in the course of the aorta. Some blood was ordered to be taken from the arm, and the system to be brought slightly under the influence of mercury.

July 8.—Mild mercurial action has set in, but no mitigation of symptoms.

9.—A paroxysm of dyspnœa came on last night, which threatens immediate suffocation. Mr. Smyly was sent for to perform tracheotomy, but on his arrival the spasms had subsided, so that he did not think it necessary to operate.

12.—The paroxysms recur every night. The patient is obliged to sit up in bed, and fix his arms to enable him to breath.—R. Mist. camph. ℥viij, Ant. tart. gr. ij, Tr. hyosciam. ʒij, St. ℥j, om. hora.

20.—Stridor and aphonia are not at all relieved, but he has suffered very little from the dyspnœa, since last report.

21.—Had a dreadful paroxysm of dyspnœa last night, followed by the expectoration of a large quantity of muco-purulent matter. Ordered Decoct. polyg. senegæ with carb. am.

23.—Died this morning, at six o'clock, in a horrible fit of spasm of the glottis, which came on suddenly while asleep.

Autopsy fifteen hours after death.—On opening into the thoracic cavity, the right lung did not collapse, the left was borne down by strong adhesions, and masses of mixed lymph and coagulated blood were deposited on the pleural surface—the results evidently of hemorrhagic pleurisy. This lung, too, was very small, not more than half the size of the right; the upper portion was dark coloured and engorged; very friable, breaking down readily under the fingers. The lower part was also congested, but crepitated on pressure. The right lung was emphysematous, and studded with spots of lobular pneumonia. No tubercular deposition was discovered in any part. On slitting up the windpipe, the larynx and epiglottis were found in a perfectly healthy state: the commencement of the trachea was slightly vascular, but its inferior portion was of a deep red colour: the left bronchus was in a similar condition. On the left lateral wall of the trachea, just at its bifurcation, a small speck was observed as if an aperture were about to form there; an incision in this part laid open a small aneurismal sac, filled with a firm fibrinous coagulum. It sprung from the postero-inferior wall of the aorta, nearly opposite to where the left subclavian artery is given off; it was of an irregularly oval shape, and lying in contact with the superior part of the left bronchus. One extremity impinged on the side of the trachea, the other rested against the bronchial tube, that supplied the upper portion of the lung, diminishing its calibre considerably; while the bronchus going to the inferior portion of the lung, suffered little, if any, pressure. There was another thimble-like aneurism, besides the greater one. The internal surface of the aorta was rough and uneven, and a quantity of atheromatous matter

was deposited under the lining membrane. The heart was healthy.

For the foregoing extremely interesting case, I am indebted to the kindness of the gentlemen composing the Meath Hospital staff. It will readily be seen that, during the patient's life time, there was not a single symptom that could give rise to a supposition of the true nature of the case. The feebleness of respiration in the upper portion of the left lung, together with the atrophy of the subclavicular region and tracheal breathing, were so many evidences of incipient phthisis, rendering unadvisable the operation of tracheotomy, the propriety of which might under more favourable circumstances have been entertained. The restriction of the respiratory obstruction to the upper portion of the lung; the hitherto healthy state of the constitution, untainted by syphilis or the exhibition of mercury, were all facts unfavourable to a supposition of the existence of an aneurismal tumour, the possible presence of which, however, was suggested by Dr. Lees, but rejected by him, as well as by Mr. Smyly and Dr. Stokes, on the above grounds.

The case, as observed by Dr. Stokes at the post-mortem examination, furnishes a new fact of considerable importance, in the differential diagnosis of this class of diseases; this being an isolated instance of partial pulmonary obstruction as a consequence of aneurismal pressure.

On the Use of Narcotics and other Remedial Agents, calculated to procure Sleep in the Treatment of Insanity.—The following is an abstract of an essay under the above title, which appears in the medical press, coming from one of the candidates, for the Lord Chancellor's prize of ten guineas, lately awarded by the King and Queen's College of Physicians:—

The author selects opium as the usually received type of the class of narcotics, and after some preliminary observations on its mode of action, according to the proportions administered, observes that the theory of its double operation, producing in moderate doses first stimulating and then depressing effects, and in large doses producing at once depressing effects, has puzzled most physiologists and writers on materia medica; but it appears to him sufficiently simple and explicable, by the fact that though the action of the heart be primarily accelerated, transmitting an increased quantity of arterial blood to the brain, and giving to that organ an additional stimulus, yet the effects of narcotics upon the organs of respiration, being either *negative* or directly the *reverse*, a want of equilibrium between the respiratory movements and those of the heart is the consequence; by which it follows, that the venous blood ceases to undergo the necessary changes with sufficient rapidity. It fails to produce a sufficiently stimulating effect upon the left ventricle, whose action becomes gradually slower; and the nervous centres not only receive less blood, but the quantity received is imperfectly decarbonised, and the primary stage of excitement is succeeded by one of depression.

After poisonous doses the respiration at once becomes slower than natural, the blood being imperfectly decarbonised from the beginning, and the heart's action quickly becoming feeble, followed by the other signs of poisoning by opium. In addition, he observes that as opium checks the secretions, excepting only that of the skin, the formative materials of these secretions are retained in the blood, tending still further to vitiate it.

Insomnia, he remarks, is not necessarily a symptom of insanity, as this term is generally understood, many insane patients sleeping as well as if in their perfect senses; and when it is a symptom, its removal is not necessarily followed by amelioration of the disease. In certain stages or forms of insanity, insomnia is more frequently present than in others; for instance, in acute mania, and not uncommonly in the chronic form of the disease. In delirium tremens, which must be looked on as a variety of insanity (though differing in being more under the influence of medical treatment), insomnia constitutes one of the most prominent symptoms. It is often well marked, too, in puerperal mania.

As insomnia may be dependent upon very opposite conditions of the circulation, now accompanied with signs of inflammation, and again with an entirely opposite condition, the kind of treatment adopted to procure sleep must differ materially in different cases. The early stages of mania are often illustrative of the former condition in an eminent degree; the indication of treatment here should therefore be to tranquillise the circulation, to lessen the cerebral irritation, and diminish excitement by means of bloodletting, shaving the head, warm baths, &c.; while in delirium tremens, which presents an example of the converse state of the system, the efficacy of narcotics, particularly opium, either alone or in combination with camphor, subcarbonate of ammonia, or tartar emetic, is most marked.

In puerperal mania, also, he observes, which is usually accompanied by nervous excitement and debility, the value of sedatives is well illustrated.

The writer next enters into a detail of the various remedies calculated to procure sleep in the treatment of insanity, and the rules which should regulate their employment, and concludes with the following summary:—

1st. That insomnia is not an essential symptom of insanity, and its removal is not necessarily followed by amelioration of the disease.

2nd. Insomnia in insanity arises from very distinct causes, and the remedial agents calculated to procure sleep, differ materially in the different forms of the disease.

3rd. Narcotics are adapted to but few cases of insanity (as this term is commonly understood), and are decidedly contra-indicated in the early stage, or in the acute form of the disease.

4th. In puerperal mania and delirium tremens, opium, variously combined, constitutes the most effectual remedy.

5th. The chronic forms of insanity, to which narcotics are best adapted, are those which in their symptoms approach most closely to delirium tremens.

6th. In the remaining cases, insomnia will be more effectually relieved by exercises in the open air, or by employment, so as to fatigue the voluntary muscles, and by amusements of various kinds, so as to divert the mind, combined with a full and nutritious diet, than by the exhibition of narcotics.

The principal doctrines laid down in this essay, are not only those in general adoption by the profession, but are consistent with the improvements suggested by the most experienced and enlightened physicians who have made this branch of diseases the subject of study.

The suggestion of the Lord Chancellor is not only praiseworthy, but valuable as far as medical science is concerned, and the idea of awakening a more correct attention, and directing a more close and critical analysis of a disease so frequent and so formidable, bespeaks a degree of benevolence of a superior character. It is to be hoped this plan may be followed up on a more enlarged and liberal scale, if not by individuals holding a high position in society, at least by institutions which have ample funds at command.

In such an undertaking Trinity College would be bound to take the lead, and, I should think, the College of Physicians and of Surgeons in Ireland, as far as their funds permitted, would follow the example.

In the theoretical part of the essay, the author has given a very ingenious explanation of the double operation of opium. I cannot, however, think it quite conclusive, for, as far as my observation applies, I have noticed that where the circulation is excited by opium, there is a corresponding excitement of the respiratory functions, and that when the latter is lowered, it is secondary to, and apparently dependent on, the approach of narcotism. The old explanation, therefore, or adoption of the terms *vis medicatrix naturæ*, would probably throw us much light on the point in dispute; the nervous system lowered into inordinate action, as it were, and struggling against the narcotic effects of the medicine, until its energies become exhausted.

Even suppose the balance between the respiratory and circulating systems to be destroyed, as laid down by the writer, another question equally difficult of explanation presents itself, viz.: How should a medicine possessing the power of stimulating the nervous system depress the respiratory functions?

On the subject of delirium tremens, the essayist might perhaps be more explicit in reference to those cases which would call for the exhibition of tartar emetic, for the cases in which this medicine is efficacious are certainly not identical with those in which opium operates so successfully.

I should say that there are probably as good reasons for classifying delirium tremens, as there are for classifying mania, and that cases occasionally occur in which a hot skin, excited vascular action, and suppressed secretions, decidedly forbid the administration of opium; at least, in many fatal cases of delirium tremens, evidences of inflammation of the brain have been revealed, while in other cases no traces of any lesion could be found.

NOTICES TO CORRESPONDENTS.

☞ *Subscribers who are in arrear since Midsummer, are requested obligingly to forward their remittances. By paying in advance for the year, a saving is effected to them, and much trouble about accounts spared us. Our rule is to be paid in advance.*

An Old Subscriber.—*A duly qualified English practitioner would be allowed to practise among* his countrymen *in France.*

Socius *can of course produce proof of his first apprenticeship having been duly completed, with the witnesses to his indenture. This is all that is requisite to prove the fact. With regard to the second question, an apprenticeship of two years is not sufficient, but if our correspondent be transferred to some London practitioner, his term may be completed during the period of his attendance on hospitals.*

Communications from Dr. Rigby, Dr. Wright, Dr. Lewins, Dr. Costello, and Dr. Knox will appear in our next.

Numerous other communications have been received which we have not yet had sufficient time to notice. We should be obliged if our correspondents would favour us with their communications as early in the week as possible.

A Subscriber, Exeter, *should authenticate his statement in a private note to the Editor.*

A Clerk.—*We do not generally notice the questions of non-professional persons; however, as an answer to our correspondent's question is certainly not giving medical advice, we may state that the neighbourhood of Hampstead is, we believe, as salubrious as any in the suburbs of London.*

Mr. Atkinson's *request would have been attended to at first had his letter been duly dated. As, however, we have several subscribers of the same name, our publisher was uncertain to whom the order referred.*

A Subscriber, Macclesfield.—*A licentiate of the Apothecaries' Company will certainly be permitted to enrol his name as a member of the National Association, if he apply to the secretaries for that purpose. We believe all existing duly licensed practitioners will be allowed to register as Members of the new College.*

A Surgeon *has written us a severe critique on a case of peritonitis which has recently appeared in a medical journal. Our correspondent remarks that some observations on the conduct of a Newcastle lawyer coroner look strange when published in a London medical journal, and contrasted with "the well-known position of a Middlesex 'functionary,' with reference to that portion of the profession in his district, and the habit he has of shirking their services on all possible occasions." He concludes by giving his opinion "that a public functionary who disregards all the usual rules recognised in the discharge of his duties, becomes a great public nuisance."*

Syronicus.—*We never reply to such questions.*

Erratum.—*By an incomprehensible blunder of our printer, by which the heading of the continued paper on Phrenology was reprinted from memory, the titles of the celebrated Edinburgh professor of logic were misgiven. It is unnecessary to say that his connection is not with the University of Cambridge, but with that of Edinburgh.*

The letter of Medicus *on the new "humbug" of a proposed new measure is under consideration*

The complaint on the exclusion of medical evidence should have been authenticated.

Dr. Storer's paper has been received.

THE MEDICAL TIMES.

SATURDAY, AUGUST 16, 1845.

Quo teneam vultus mutantem Protea nodo?

THE "Physic and Surgery" Bill, as "amended by the Committee and on recommitment," has just been issued. It differs from the former draft, as published by us in May last, only in a few points, but those are mostly material. We shall briefly analyse the proposed changes.

In clause 1, the 14th and 15th of Hen. 8, cap. 5, is distinctly mentioned as a statute not repealed. In the former draft it was not noticed in any way, and certainly was not repealed. The present change was introduced, therefore, to satisfy any uneasiness in the heads of the College of Physicians. The statute thus exempted from repeal is the one by which the College hold all their principal privileges, and the repeal of the other acts, some of which more or less limited the operations of that corporation, will probably invest it with powers which should be jealously inquired into before the present Bill be allowed to pass.

In clause 2 we have the new formation of the Council of Health. We reprint it.

The Council of Health.

"And be it enacted, That a council shall be established, which shall be styled "the Council of Health," and that one of her Majesty's principal Secretaries of State shall be a member of the said council, in right of his office as Secretary of State; and that the other members of the said council shall be such persons, not more than twelve, whom her Majesty, with the advice of her Privy Council, shall deem fit to be members of the said council."

The tenure of office—the affairs of secretaries' expenses—president, vice-president—place and time of meeting—minutes of proceedings—occupy the next seven clauses, and remain as in former drafts. In clause 9, the register is provided for as before, *new* candidates paying £5 as Physicians and Surgeons, and £2 as General Practitioners, and in clause 10 we have the mode fixed of making and registering

General Practitioners.

"And be it enacted, That every person shall be entitled to be registered by the council as a general practitioner who, at the time of the passing of this act, shall be legally practising, or entitled to practise, as a physician, surgeon, or apothecary, in some part of her Majesty's dominions, and who shall be qualified to be enrolled, and shall enrol himself, as a member of the Royal College of General Practitioners of England, and also every person who shall have attained the age of twenty-two years, and shall have been examined by the colleges hereinafter named—that is to say, if in England, examined by the Royal Colleges of Physicians and Surgeons of England; or, if in Scotland, examined by the Royal Colleges of Physicians and Surgeons of Scotland; or, if in Ireland, examined by the Royal Colleges of Physicians and Surgeons of Ireland, after such proof as shall be satisfactory to the examining colleges, that he has applied himself to medical and surgical studies during at least five years, of which at least three years shall be in universities or hospitals, or public medical or surgical schools recognised by the Council of Health, and in every case shall have received letters testimonial from each of the bodies by which he shall have been examined of his being duly qualified to practise as such general practitioner, provided always that such examination by the Royal Colleges of Physicians and Surgeons of England shall be conducted before a joint board of examiners, to be appointed separately by each of the said colleges; and that no person shall be qualified to offer himself for such examination by the Royal Colleges of Physicians and Surgeons of England until he shall have been examined by the Royal College of General Practitioners of England, and shall be by that college admitted a member of the last-mentioned college, except persons holding any medical or surgical rank in her Majesty's army or navy, or in the service of the Honourable East India Company; but no person holding any such medical or surgical rank as last aforesaid, who shall have been examined by the Royal Colleges of Physicians and Surgeons of England, shall thereby acquire any right to be registered as a general practitioner until the end of five years after such examination, unless he shall have been previously examined by the said College of General Practitioners, or shall be afterwards so examined within the said period of five years."

Our readers will notice here the changes of which we had forewarned them. The General Practitioner is no longer to be a "*Fellow*," but a "*Member*," of his College; his College is no longer to be the College of General Practitioners in Medicine, Surgery, and Midwifery, but "the College of General Practitioners," and the preliminary examination wholly disappears to make way for a system of two complete medical examinations by two medical examiners, on the same subjects—one by the General Practitioners, the other by a joint Board of Surgeons and Physicians. The object of the latter examination is, of course, to offer some decent pretext for extracting from General Practitioners a large sum in support of the old institutions. The Report of the Deputation, published in another column, shews that in their negociations it was agreed, that the second examination should entitle the candidate to Membership in the College of Surgeons. The bill, however, very curiously omits to make any provision of this kind. This must, of course, be an oversight.

In clause 11, the Surgeons, by which are meant Fellows, are allowed to be examined at twenty-five, instead of twenty-six, and after five years' study instead of after six. This is a concession to the College Council, who thought that twenty-six was too high an age, and six years' study too long a course of preparation for their Fellowship. The depreciation of *qualification* was to them counterbalanced by the expected *elevation of fees*.

Clause 13 gives us the following provision:—

"And be it enacted, That no person shall be qualified to offer himself for examination by the Royal College of Physicians of England, Scotland, or Ireland, for the purpose of being registered as a physician, or by the Royal College of Surgeons of England, Scotland, or Ireland, for the purpose of being registered as a surgeon, who shall not have previously passed the like examination by the several Royal Colleges of Physicians and Surgeons of England, Scotland, and Ireland respectively, as is required to be passed before those colleges respectively by persons who have been examined by the said Royal College of General Practitioners, in order to entitle them to be registered as general practitioners."

By clause 14, the Council of Health is empowered to relax the provisions of the Bill in favour of the present body of medical and surgical students.

By the next two clauses, General Practitioners, Surgeons, and Physicians, are under a penalty to pay fees and belong to the Colleges of the country in which they may reside. Provision of an obscure kind is made for the connection of General Practitioners with the College of Surgeons of Scotland as Licentiates, and with some other College or Colleges not named, in some other parts of the country.

Qualifications and fees are to be made as uniform as is "practicable and convenient," by the Council of Health (clause 17), and we then come to the following arrangement:—

Licentiates in the Faculty of Medicine.

"And be it enacted, That it shall be lawful for any university of the said United Kingdom to grant the degree of Licentiate in the Faculty of Medicine to any student of the same university who shall have attained the age of twenty-two years, and shall have applied himself to medical and surgical studies during at least four years in universities, hospitals, or public medical or surgical schools, recognised by the Council of Health; and that every such Licentiate in the Faculty of Medicine, being also examined, and having received letters testimonial of his qualification in the manner hereinbefore prescribed in the case of general practitioners, shall be entitled to be registered by the said Council of Health as a Licentiate in the Faculty of Medicine, with all the rights, privileges, and liabilities of a general practitioner, subject to such general regulations as shall be made by the said council concerning the registry of general practitioners."

The restriction on bye-laws, registry of students, presence of members of the Council of Health, on examinations, exclusion of non-registered from public appointments, exception of registered Practitioners from serving on juries, &c., are then provided for. By clauses 24 and 25, registered Physicians and Surgeons are allowed unlimited practice (except as Apothecaries); and by 26, General Practitioners are specially entitled to recover for medical and surgical attendance. By clause 29 this privilege is restricted to them and persons now in practice. The Supplementary Register, giving present Practitioners all former rights, is thus spoken of (clause 27):—

Supplementary Register.

"Provided always, and be it enacted, That during twelve calendar months after the passing of this act, every person legally practising, or entitled to practise, on the day before the passing of this act as a physician, surgeon, or apothecary, in any part of the United Kingdom of Great Britain and Ireland, and during the period of two years after the passing of this act, every person legally practising, or entitled to practise, on the day before the passing of this act as a physician, surgeon, or apothecary, in any of her Majesty's colonies and foreign possessions, although not registered, shall continue to enjoy the same privileges and exemptions, and be qualified to be appointed to the same offices, and to practise in the same manner as if this act had not been passed, and no further or otherwise, unless registered under this act; and the said council, on the application at any time of any person legally practising, or entitled, on the day before the passing of this act, to practise as a physician, surgeon, or apothecary, in any part of the said United Kingdom, shall cause the name of such person to be registered in a supplemental register as a physician, surgeon, or apothecary, as the case may be, specifying the nature of his qualification, and whence derived, on production to the said council of his diploma, license, or certificate, or such other proof as shall be satisfactory to the said council, that on the day before the passing of this act he was so practising, or legally entitled to practise, and on payment of a fee of five shillings, which fees shall be applied toward the expenses of this act; and every such person, upon being so registered, shall continue to enjoy the same privileges and exemptions, and be qualified to be appointed to the same offices, and to practise in the same manner as if this act had not been passed, and no further or otherwise."

The Register is to be published annually, is to be prima facie evidence of qualification, or the absence of it. A penalty is provided (clause 30) for unqualified persons practising in public offices. All unqualified persons acting as Apothecaries

(clauses 31 and 32) can be prosecuted by the College of General Practitioners, and punished by penalties of £20 for each offence:—

"And be it enacted, That every person who, after the passing of this act, shall act or practise as apothecary in any part of England, without having been registered by the said Council of Health as a general practitioner, shall for every such offence forfeit and pay the sum of twenty pounds, to be applied to the use of the Royal College of General Practitioners of England, and to be recovered by the said college by action of debt in any of her Majesty's courts of record at Westminster."

And by the next clause it is enacted, that pretenders to qualifications, no matter under what medical designation, may be prosecuted for a misdemeanour. Persons guilty of felony or fraud, may be struck off the Register as before, and the privileges of Oxford and Cambridge are saved.

The Bill ends with a provision that it may be amended or repealed during the session.

Quod petiit spernit; repetit quod nuper omisit;
Æstuat, et vitæ disconvenit ordine toto;
Diruit, ædificat, mutat quadrata rotundis!

THE summary of the *amended* Bill that we have given above, just shows how possible it is for the omnipotence of Parliament to perform the very paradoxical feat of *amending* a measure into *deformity*. Sir James Graham has surely been bewitched. The fascination exercised over him by Dr. Paris and Sir Benjamin Brodie, would suggest that they had cozened him to take a love-philter. In the name of wonder, how could a measure so well received by the profession, when presented to it so recently as May last (three times altered and amended, on each occasion after considerable deliberation), how could this measure have suddenly turned, like Oberon to Titania, so loathsome to the eyes of the Home Secretary, that this "Bottom" of a Bill before us should now be introduced to us as the sole object of his capricious affection? The last Bill showed certainly one great deformity in that preliminary examination, by which the future Practitioner was obliged to pass through a court of censors, formed by Colleges with which he was to have nothing to do, a Board established for no other purpose than to give the half superseded Colleges additional patronage and the command of some extra fees. This was an arrangement which could serve no purpose of utility, and conflicted with every other provision contained in an otherwise excellent measure. But the present Bill presents us with the deformity of a double examination, marked by even far more absurdity. The General Practitioner is to be thoroughly educated by his own College—to have his competency attested beyond all doubt—for the Minister's Council of Health has the power of enforcing the strictest examination that can be required;—yet he is subjected by the present Bill to a second examination, on the very same subjects, under members of *opposing* Colleges: and all this, for what? As a pretence for making the General Practitioners, who are, for the future, by this Bill, to be wholly unconnected with the two Colleges of Physicians and Surgeons, pay towards the support of both large sums of money. The General Practitioner is not to be a Surgeon—he is not to be a Physician—yet he is to contribute to keep up establishments for both. A more preposterous arrangement in reference to the public, or a more unjust one to the profession, it is impossible to conceive. It is disgraceful in the Colleges to seek unearned contributions from a portion of the Profession they have excluded, maligned, and affected to contemn; it is still more disgraceful, if they must have the tax, to extract it through the troublesome and oppressive medium of a hostile and utterly unneeded examination.

Under all circumstances, indeed, this second examination is an annoying corporate farce. True, the understanding come to by the deputation of the National Association, had stripped it of much of its vexatiousness. To them it was conceded, that if they would submit to what was indispensable for the support of the old corporations, their members should receive a consideration for their money in an extra diploma from the College of Surgeons, with the right of access to its library and museum. The arrangement answered two ends: it met the desires of that portion of the body of General Practitioners who still clung to a connection with the College of Surgeons, and tended to throw an extra *éclat* on the young member of the New College, well calculated to support his attainments as a member of his class, and to recommend him to the confidence of the public. The scheme, from its native absurdity, would evidently be but a temporary one, and, considered in that light, might not be unserviceable to the new incorporation itself during the interval required before it could develope its full capabilities, and prove to the public that its diplomas were an unerring indication of scientific competency.

The provision thus promised to the deputation, and which took away the sting of the second examination, *does not appear in the bill!*

It is right, under these circumstances, that Government should know that the General Practitioners' partial support of their Bill will require, as a *sine quâ non*, that, if there is to be a second examination, that second examination shall give a second collegiate diploma. As we understand matters, there was a clear promise that such should be the case, and we will suppose, till better informed, that the omission in the Bill originates entirely in an oversight. The Bill must be opposed, if that concession be not fully made. We are glad of a raised qualification—we are pleased at a board of general revision—we know the benefits of a good registration, but all these together, in their most unexceptionable form, would not tempt us into the weakness of submitting to have the General Practitioners made mere milch cows, by Act of Parliament, for the support of institutions perishing of the premature decay caused by very extravagant impolicies.

BOOKS RECEIVED.

On the Nature, Causes, Prevention, and Treatment of Acute Hydrocephalus, or Water-Brain-Fever. By THOMAS SMITH, M.D., &c. London, 1845. 8vo. pp. 168.

If Dr. Smith will take our advice he will not, for his own reputation, attempt again to write a book which endeavours to conciliate both the public and the profession; nor will he enter upon the consideration of such profound subjects in so off-handed a manner. We doubt very much whether a popular treatise upon any specific malady be desirable, although we willingly allow that the general principles of hygiene (such as relate to the diet, dress, &c., of infants and children), if ably and lucidly laid down by one of ourselves for the use of mothers and nurses, would be of service. Fortunately, a third part of Dr. Smith's treatise is taken up with this kind of matter, more especially in relation to the conduct of the mother during pregnancy and lactation; as to the style, however, and modes of expression adopted, we feel ourselves called upon to enter a caveat, in spite of Dr. Smith's own confession, that the former is neither elegant nor easy. What the word "cogging" (p. 76) implies we know not, and we are equally ignorant of the meaning of "cockering" (p. 78), and consider that there is some slight obscurity about the following paragraph. Speaking of the difficulty of accounting anatomically for the increase of hydrocephalus, Dr. Smith writes—"In the same sense it is difficult to account for the simplest facts in nature; as, for example, why a horse has four legs. When parents ask me for an explanation, I refer them to their flower-pots, and to the *languid circulation of the interior gardens* in large towns."—(pp. 90—91.)

The practice Dr. Smith recommends at page 136 of the parent seeing that her child's teeth are regularly cleaned night and morning by brushing them with *soap* and *water*, appears peculiar. With respect to other views promulgated in this popular Treatise on Hydrocephalus, the more prominent are that this disorder is—

1st. "An idiopathic nervous fever, strongly allied to the febris lenta nervosa of adults."—(p. 65.)

2nd. That "the latent causes I take to be a strumous or lymphatic constitution, engendered not unfrequently by a too highly excitable condition of the nervous system in the mother, which deprives the fœtus in utero of its due supply of nutrient aliment."—(p. 47.)

3rd. "That if scrofula be not an hereditary disease, hydrocephalus is not."—(p. 59.)

4th. "That three generations, under good management, would suffice to eradicate scrofula from any family."

5th. That "treat hydrocephalus as you would any other nervous fever, and such treatment will give you the best chance of success."—(p. 162.)

6th. That "free catharsis, free diuresis, or free diaphoresis, by whatever means these separate states of the system can be obtained, offer the most reasonable prospect of recovery."—(p. 166.)

7th. That the "disposition to vomiting may be prudently encouraged (except in the more inflammatory species impressed and enumerated by the moderns), and the common precaution, 'lest by vomiting we increase cephalic determination, or promote serous or sanguineous effusion,' is a mere verbal bugbear."—(p. 163.)

The terms *water-brain-fever* employed by our author, sounded strangely to our ears—not less did the "Narrative of the two dogs, Jowler and Keeper" (p. 86), until we recollected the work was not ostensibly for the profession, although we found the words "Conspectus Medicinæ Theoreticæ, J. Gregory, M.D., 1830," at the foot of one page, and *Liebig* and *Boerhaave* referred to at the bottom of others. Dr. Smith will excuse us, but if he had not courted the profession at the same time he was so intent upon angling for the public, we should have thought ourselves bound to look less sharply on his faults, which in truth are not grave, and more favourably at his merits, which, after all, are not unpromising.

Lives of Men of Letters in the Time of George III. Charles Knight and Co.

Lord Brougham is one of the most encouraging instances that can be cited in favour of the policy of those men who aim at celebrity in everything; and yet what, after all, is his position? Qualified, if he had concentrated his powers upon *one* object, to take the highest possible rank, by too much ambition he has defeated his desires; and, now, not far from the close of his history, he stands in the predicament of a man not *great* in anything. Perhaps, however, we are wrong in our conjecture of his capacity. Certainly it is the received opinion that where nature has implanted the germ of complete greatness, it will also give the single bent which is necessary to its development. True power is rigid in its devotion to *one* end, and in all its excursions into other fields brings back that only which will enrich its own. If this doctrine be correct, it follows that the desultory mind, uncertain in its action, is alike uncertain, and consequently weak, in execution. It is a small thing to say of Lord Brougham, that he is amongst the best of smatterers; but small as it is, it is the most that can be said of him. He has, in the course of his life, been lawyer, politician, orator, man of science, theologist, and historian. In which of these characters can we consider him an extraordinary man? An extraordinary lawyer, indeed, for his standing, because he knew comparatively nothing of law. Not an extraordinary politician, because he has "turned, and turned, and turned again." His science and theo

logy were repetitions of what other men had thought and written. On these subjects he belongs to that class of readers whom Coleridge has compared to a sponge, returning what they have received, only a little muddier. Lastly, to find his worth as an historian we need only peruse what he has written in the book before us. And what is its value? Superior, we confess, to the common run of compilations, but as a work pretending to sketch down in words the likeness of men's minds, as faithfully as the painter their portraits upon canvas, it is like his lordship's professed political consistency—a nullity.

Still, the volume will repay perusal; it is better, much better, than ordinary books upon men's lives. The style is inelegant, indeed; the order of propositions ill-placed, and their intention incompletely worked out; but, with all that, the book deserves to be read. It has something—undecided, but indicated—which, if it do nothing more, will be a caution to historians of what they should avoid, and to readers of what they should commend.

How to Humbug the Profession. By THOMAS WAKLEY, Surgeon, M.P., late surgeon and druggist of Argyle-street, (anti)-Medical Coroner; Member of the Council of the *late* British College of Medicine; Member of the Council of the *late* British Medical Association; Member of the Committee of the *late* Medical Protection Assembly; *non*-Member of the Council of the Provincial Medical Association; *non*-Member of the Committee of the National Association; *non*-Member of several learned Societies; author of several Medical Bills (not passed), &c. &c. &c.

This is so interesting a little brochure, that we shall publish it entire in another number.

UNIVERSITY OF LONDON.

BACHELOR OF MEDICINE. FIRST EXAMINATION. PASS EXAMINATION.—1845.

Anatomy and Physiology; Examiners, Mr. Kiernan and Professor Sharpey.—Monday, August 4; Morning, 10 to 1.—1. The bones of the face and the ethmoid being removed, describe that portion of the basis of the cranium included between the superciliary ridges of the frontal bone in front, a line extending between the mastoid processes, and in front of the condyles of the occipital bone, behind, and laterally between lines drawn from the external orbital processes of the frontal to the mastoid processes. First mention the bones, and those portions of them which enter into the formation of the part to be described; then commence the description at the superciliary ridges, and describe the surfaces, sutures, processes, and foramina, in the order in which they are met with, mentioning the muscles when describing the parts to which they are attached. What is the mode of developement of the frontal and occipital bones, and in what condition are these bones at birth?

2. Commencing at the integuments, give an account of the parts successively exposed in the dissection required to display the structures entering into the formation of the inguinal and femoral canals: the answer to include a description of the appearances seen on the inside after removing the peritoneum, with an account of the spermatic cord, and of any varieties in the origin and course of the obturator artery which relate to the subject of the question.

3. Describe the steps of the dissection required to display.—1st, the course of the radial artery, from its origin to the point at which it disappears between the metacarpal bones of the thumb and fore-finger, and the branches given off in this part of its course; 2nd, the course of the posterior tibial artery from its origin to its division into the plantar arteries, and of its branches, as far as they can be seen on the back of the leg. The parts are to be described in the order in which they are met with, and all the relations of the vessels are to be mentioned.

4. Give an account of the diphragm and of its uses, mentioning the muscles which act in concert with it. Describe the origin, course, and distribution of its vessels and nerves.

5. Describe the cartilages of the larynx, and their mode of connexion with each other.

Afternoon, 3 to 6.

1. Give an account of the joints formed by the radius and ulna with other bones, and with each other; the answer to include a description of the articular surfaces of the several bones, and of the cartilages, synovial membranes, and ligaments. Describe the movements which take place in these joints, mentioning the muscles by which they are effected, and the classes of joints to which they belong. In what respects do the movements which take place in these joints differ from those which take place in the corresponding joints of the leg.

2. Describe the parts met with in dissecting a portion of the posterior region of the trunk, included within three lines corresponding to the borders of the latissimus dorsi muscle; the dissection to be carried down to the vertebræ and quadratus lumborum.

3. Give the dissection required to expose the subscapular artery and its branches, describing the parts met with in the dissection as far as they are necessarily brought into view.

4. Give the anatomy of the prostate gland, describing its form, size, situation, connexions, and structure, with the part of the urethra which passes through it.

5. Describe the position and structure of the heart and pericardium. Give a brief account of the passage of the blood through the cavities of the heart, and of its entrance into the aorta and pulmonary artery; and of the contractions, impulse, and sounds of the organ.

6. Give an account of the structure, physical properties, and chemical composition of cartilage and fibro-cartilage, distinguishing their several varieties.

Chemistry; Examiner, W. T. Brande, Esq.—Tuesday, August 5; morning, 10 to 1.

1. State the theory of latent heat, and illustrate it by the details of Black's experiments on the freezing of water and thawing of ice; and on the formation and condensation of steam. Explain the meaning of the term specific heat, and describe the modes of determining the "capacities of bodies for heat."

2. Describe the action of the common electrical machine, and the theory of the reception and retention of the charge by the respective conductors.

3.—Explain the formation of a simple and of a compound voltaic circuit—the theory of their action; and the phenomena of the electro-chemical decomposition of water, and of solutions of sulphate of soda and sulphate of copper.

4. What is meant by the terms "atomic weights," and "equivalents" of bodies? How are atomic weights determined? What are the arguments for and against the adoption of whole numbers as representing chemical equivalents; and what are the equivalents upon the hydrogen scale, and what the respective specific gravities (air = 1) of the following gases and vapours:—oxygen, nitrogen, chlorine, iodine, carbonic oxide, carbonic acid, sulphurous acid, cyanogen, ammonia?

5. What is ammonia? What relations does it bear to the theory of ammonium and of amidogen? What are the accepted proofs of the existence of the two last-mentioned compounds? What are the ultimate elements of sulphate of ammonia, and how may its proximate constitution be represented in reference to the different theories?

6. Represent in symbols the ultimate and the proximate composition of ferrocyanide of potassium, and of the precipitates which it occasions in solutions of the oxides of silver and lead, and of peroxide of iron.

7. What are the principal elements of organic bodies? How may they be qualitatively and quantitatively determined?

8. What are the ultimate constituents of the common varieties of coal? What are the principal products of their destructive distillation as carried on for the production of coal-gas? and how are those products separated?

9. What is protein? What are the principal organic products which afford it; and with what elementary substances is it usually associated?

10. Draw a comparison between the chemical physiology of vegetables and that of animals.

The bottles marked A, B, and C contain certain saline solutions—they are accompanied by appropriate tests, by which the nature of their respective bases and acids may be recognised—you are requested to name these, and to write their respective symbols and equivalents.

Materia Medica and Pharmacy; Examiner, Dr. Pereira.—Tuesday, August 5; afternoon, 3 to 6.

1. Enumerate the most important officinal diuretics, and explain their respective peculiarities of operation. State your opinion, and the reasons on which it is founded, of the propriety of administering diuretics in renal dropsy with albuminous urine. In the use of saline diuretics, what circumstance, appertaining to the density of their solutions, has Liebig suggested the practical importance of attending to?

2. Describe the process of the London Pharmacopœia for making pulvis antimonii compositus, and explain the chemical changes attending it. State what are the ordinary constituents of this substance, and how the presence of sesquioxide of antimony in it is to be detected.

3. Give a botanical description of valeriana officinalis, and mention the active principle of, and the mode of extracting it from, the root of this plant.

4. How can the presence of chloride of potassium in chlorate of potash be detected? State how you would proceed to determine the presence of subacetate of lead in the sugar of lead of the shops?

5. Describe the effects, uses, mode of exhibition, and dose of Senega root.

6. What are the effects of an overdose of opium, and what is the most appropriate method of treatment in poisoning by this substance?

Botany; Examiner, Rev. Professor Henslow.—Tuesday, August 5; afternoon, 3 to 6.

1. Define, and name examples (where the case admits), illustrating the following terms:—Capitulum—Tetradynamus—Petiolus—Lodicula—Stoma—Atropus—Serratus.

2. Mention the chief characteristics of the following orders:—Boragineæ, Leguminosæ, Aroideæ.

3. Give the more important characters in the following genera:—Valeriana, Samolus, Caucalis, Scirpus.

N.B.—In this question you are required to describe precisely the characters of the several floral whorls, those of the fruit and seed; and to state the peculiarities of Æstivation, Vernation, and Foliation.

UNIVERSITY OF LONDON.

BACHELOR OF MEDICINE.—FIRST EXAMINATION.—1845.

First Division.—George Birkett, Charing Cross Hospital; William Brinton, King's College; John Climson Day, London Hospital; Henry Fred. Augustus Goodridge, University College; Daniel Hooper, Guy's Hospital; Thomas Henry Huxley, Charing Cross Hospital; Walter Johnson, Guy's Hospital; George Henry King, Guy's Hospital; Cornelius Winter Randell, University College; William Henry Ransom, University College; John Reid, King's College; Joshua Harrison Stallard, Queen's College. Birmingham; Samuel Hopkins Steel, King's College; Alfred Williams, University College; Ewing Whittle, Royal College of Surgeons in Ireland.

Second Division.—John Thomas Arlidge, King's College; James Cato De Castro, University College; Daniel Ithiel Edwards, University College; Henry Thomas Hartnoll, St. Thomas Hospital; William Henry Holman, London Hospital; James Johnston, Queen's College, Birmingham; Thomas Palmer, Apothecaries' Hall of Ireland; John James Rygate, London Hospital; Henry Stevens, King's College; Thomas James Sturt, King's College

OBITUARY.—We regret to announce the death of Mr. Thomas Everitt, the late professor of chemistry at the Middlesex Hospital, which took place at Lady Ellis' Asylum at Southall, in consequence of a severe scald received while in a hot bath. We propose to give a notice of this distinguished chemist next week.

A SECOND REPORT BY THE DEPUTATION OF GENERAL PRACTITIONERS.

The deputation who have been appointed with full authority on behalf of the National Association of General Practitioners to accept such a charter of incorporation for the general practitioners, as the crown might be advised to grant, and on behalf of the Society of Apothecaries, to relinquish their present privileges as soon as the terms of the proposed charter should be adjusted, under the sanction of her Majesty's advisers, to the satisfaction of the deputation, avail themselves of the earliest opportunity which has been afforded them, of reporting to their professional brethren the further progress of the negociations with the government, in connexion with the subject of medical legislation.

In communicating to the profession Sir James Graham's intention of recommending the grant of a charter of incorporation for the general practitioners, the deputation explained that it had been intimated to them, that the offer of a charter was to be regarded as part of a general arrangement; and that its acceptance, therefore, had to be considered in connexion with the other portions of the scheme.

The terms of that arrangement, as more immediately affecting the interests of the class of general practitioners, were detailed in the former report of the deputation; and the deputation stated that they had no hesitation in accepting, on behalf of the general practitioners, the proffered charter of incorporation, coupled with the conditions of the general scheme which was then contemplated.

It will be remembered that the particulars of the arangement were stated by Sir James Graham to the House of Commons, on the 7th of May; and the bill, as amended to give effect to that arrangement, was shortly afterwards printed by order of the House.

The arrangement contemplated by the amended bill has met with opposition from various quarters, and on various and widely differing grounds; and the College of Physicians, the College of Surgeons, the teachers of the London schools, and the Scotch and Irish colleges, have, each on their own grounds, urged the most decided objections to particular features of it.

The College of Physicians contended that, as that college was instituted for the promotion of medical science, it was proper that to it should be entrusted the duty of testing the qualifications of all those who were to have the sanction intended to be given by the bill, of being qualified to practise medicine, just as to the College of Surgeons was to be entrusted the duty of testing the qualification of persons to practise surgery.

The College of Physicians objected to the arrangement that persons, who had undergone a previous examination by physicians and surgeons, should be examined subsequently in medicine and surgery by general practitioners. The college further urged, as a great objection to such double examination, that it must operate as a discouragement to medical education in England, since, in Scotland and Ireland, a single examination would be sufficient to qualify for practice. With respect to the incorporation of the general practitioners, by the name of "The Royal College of General Practitioners in *Medicine*, Surgery, and Midwifery, of England," the College of Physicians pressed upon the attention of Sir James Graham, that, as the College of Physicians was specially founded for the promotion of medical science, and for the regulation of medical practice, there were strong objections to the assumption by the new institution of the title of "The Royal College of Practitioners in *Medicine*." The College of Physicians objected yet even more strongly to the latter part of the 32nd clause of the bill, which gave to the general practitioners the right to fill ALL *medical and surgical offices*, and thus, as the college insisted, confided the highest duties of the profession to the members of that class which was required to pass through the least extended education, and which was admitted to practise at the earliest age.

The College of Surgeons objected that the proposed amendments differed in principle from the bill, and from the original bill of which the heads had been submitted to the council of the college, and were inconsistent with the charter and bye-laws of the college, founded upon those "heads." The College of Surgeons found that one of the principal features of the amended bill was that of providing for the institution of a college of general practitioners in medicine, surgery, and midwifery, and expressed their surprise at the establishment of a new college, which was intended not only to embrace medicine, surgery, and midwifery, but to be co-ordinate in professional rank and importance with the existing Colleges of Physicians and Surgeons. The college stated their deliberate conviction, that, in the framing of the amended bill, the interests of the College of Surgeons, and its claims to legislative protection, had been unhappily overlooked. In particular, the College of Surgeons objected to the title of the New College—to the title of fellow being given to its members—to any power being given to the New College to examine in surgery; contending that by the amended bill the College of Surgeons would be subordinate to the College of General Practitioners, in those functions for which the College of Surgeons was specially instituted; and that the surgical examiners at the joint board might be placed in the degrading position of having a candidate, whom they had declared duly qualified, rejected at the subsequent examination by general practitioners. The college further objected that registered general practitioners were to be deemed, to all intents and purposes, qualified practitioners of surgery, and capable of filling any surgical appointment in any local or public institution; that the bill was calculated to discourage the attainment of the fellowship of the College of Surgeons, and that the College of Surgeons was in danger of being sacrificed to the views and wishes of those who hoped to annihilate it by the establishment of a rival College of Surgeons.

The power proposed to be given to the College of General Practitioners, by their charter, of appointing examiners who were not members of their own college, was understood to be strongly objected to, both by the College of Physicians and the College of Surgeons.

It was strongly urged by others, that the effect of the double examination in England would be to tempt students to pass their examination in Scotland and Ireland, where they would have to submit to a single examination only; and that the English schools of medicine would suffer in consequence. This objection was considered to apply with increased force to English candidates for medical appointments in the army and navy, and in the colonial service, inasmuch as they would have to pass, in addition to the two examinations contemplated by the bill, a third examination before the medical boards of their respective services.

The deputation refer to these objections, not for the purpose of exaggerating the points of difference which exist in the views entertained by the various branches of the profession on the subject of medical legislation, but for the purpose of impressing on the minds of their medical brethren the opposite views which are, in fact, entertained and advocated, and the consequent difficulties which embarrass the government and the legislature, in dealing with the complicated question of medical reform; and especially, of urging upon the great body of practitioners, whose interests are represented by the deputation, the absolute necessity of approaching the consideration of the subject in a spirit of conciliation and forbearance; and, prepared, in a matter in which so many apparently conflicting interests have to be reconciled, to concede their own opinion on points where concession does not imply any departure from the great principles, for the maintenance of which the general practitioners, as a class, are struggling.

It is in this spirit that the deputation have endeavoured to conduct the negociations on the part of the general practitioners of this country. The great object they have kept steadily and constantly in view, has been to uphold the character and qualification, and the status, professional and social, of the general practitioner; in one word, to render the medical attendant of the great masses of the population qualified, in every respect, for the fit discharge of his important functions; and, as a principal means to this end, to secure to the general practitioners the power of determining the course of study, and the nature of the examination to which the candidate for this branch of the profession shall be subjected, before he is permitted to enter on its practice; and it has been the constant aim of the deputation that this great principle of legislation should not be put in peril, either by undue concession to opposing views, on the one hand; or, on the other, by attaching an undue importance to the details of the machinery by which a general arrangement must be carried out.

Without referring to matters which, in the result, have become of comparatively minor importance, but which, nevertheless, demanded the anxious consideration of the deputation, the deputation were, at a late period of the discussion, called upon to decide with reference to the objections which had been urged:—

1. To the name of the New College.

2. To the power which had been claimed of appointing individuals to the examining board of the New College, who were not members of that college.

3. To the provision of the bill rendering it imperative on candidates for medical offices in the army and navy, and in the colonial service, to submit themselves to an examination by the colleges.

In communicating with the government on these points, the deputation reminded the Secretary of State that they had claimed for the general practitioners a charter of incorporation, which should recognise the individuals incorporated as practitioners in medicine, surgery, and midwifery, and should authorise them to subject the candidate for their letters testimonial, to an examination in each of those branches of medical science, and in such other branches of science as they might deem necessary, with the view of testing fully and efficiently the qualifications of the candidate to practise as a general practitioner in medicine, surgery, and midwifery, and that the government had acceded to the claim thus made by the deputation.

The deputation, after premising that they distinctly understood that they were not asked to relinquish such claim, or to modify it in any respect, stated, that if the functions of the general practitioners were clearly defined by the charter, and if authority was distinctly and unequivocally given to the New College on the face of their charter, to examine the candidates for their letters testimonial, in all such branches of knowledge, professional and general, as the council might think necessary, as a test of qualification for general practice, the object of the deputation would be attained.

The deputation assured the government of their anxiety to assist in removing every obstacle to the settlement of the question of medical reform in the present session, and that they were prepared to make any reasonable concession, for that purpose, which did not involve an abandonment or compromise of the principles on which the deputation had solicited, and the government had assented to, an incorporation of the general practitioners; that in the hope, therefore, of removing all reasonable grounds of objection, and of facilitating the passing of the bill in the present session, the deputation were prepared to assent to the following modifications, on the understanding that the power was reserved to them of withdrawing such assent, if the modifications were not agreed to, as a whole, by other parties.

The deputation stated that they would accept a charter of incorporation of the general practitioners, by the title of "The Royal College of General Practitioners of England," the general practitioners being identified in the charter with the individual at present combining the legal qualifications of a surgeon and an apothecary; and that they would assent to the New College being restricted in the choice of their examiners to the fellows of their own college.

That they would assent to candidates for medical appointments in the army and navy, and in the service of the East India Company, being qualified for such appointments by passing an examination before the respective medical boards of those services, preceded (if deemed necessary) by an examination before a joint board of physicians and surgeons.

That they would also assent to medical officers who had been actually employed in those services for a period of not less than five years, being entitled,

at the expiration of such period, to register as general practitioners without further examination, on enrolling themselves fellows of the New College.

The deputation, anxious to preserve for the future general practitioner the right of using the title of surgeon, and the privilege of admission to the Hunterian Museum and the library of the College of Surgeons, in making the foregoing concessions, expressly stipulated that individuals who should thereafter obtain letters testimonial as general practitioners, should be at liberty, on payment of a small enrolment fee, and without further examination, to enrol themselves as members of the Royal College of Surgeons, and, upon such enrolment should be entitled to use the title of surgeon, although registered as general practitioners.

The deputation desire to observe that, at the time when the foregoing communication was made to the government, they were not aware of the existence of the objections which were subsequently expressed by the Colleges of Physicians and Surgeons, to the examination by the College of General Practitioners succeeding the examination by the joint medical and surgical board.

The objections entertained to this part of the arrangement by the existing colleges, appear to be of so grave a character as to preclude all hope of carrying any measure of medical reform with the assent of those bodies which contemplated an examination by the College of General Practitioners following an examination before a joint board of physicians and surgeons; and Sir James Graham had already stated to the deputation that he was not prepared to advocate a measure of medical reform which met with the decided hostility of any of the parties with whom the government were then in communication on the subject.

At this stage of the negociations, it was intimated to the deputation that the objection might be overcome by reversing the order of the examinations, and providing that the examination by the College of General Practitioners should precede the examination of the joint medical and surgical board—an arrangement which, while it met the objection entertained by the Colleges of Physicians and Surgeons to any candidate who had passed the examination before the joint medical and surgical board, being exposed to the risk of rejection by the College of General Practitioners, would, at the same time, enable the College of General Practitioners to prevent any person presenting himself for examination before the joint medical and surgical board, who had not succeeded in satisfying them of his competency in every respect to practise as a general practitioner.

The great question for the consideration of the deputation was, whether this arrangement would effectually secure to the general practitioner the means of maintaining and elevating the standard of qualification of the members of his own class.

In the first place, the arrangement contemplates that the College of General Practitioners shall have the unrestricted power of determining the curriculum of study of the general practitioner, provision being expressly made that the power of the Council of Health to change the curriculum, shall be exercised for the purpose of extending, but not of limiting, the scheme of education determined by the New College. In the next place, the arrangement contemplates that the College of General Practitioners shall have the unrestricted power of examining in medicine, surgery, midwifery, pharmacy, and such other branches of science, professional or general, as the college in the unfettered exercise of their judgment shall think essential, with a view to a satisfactory test of the candidate's qualification to practise as a general practitioner; the controlling power of the Council of Health being exercisable for the purpose of elevating, but not for depressing, the character of the examination.

It appeared, therefore, to the deputation that this arrangement did secure to the general practitioners the efficient controul which they claim to possess over the education and examination of their own class.

The arrangement further contemplates that on passing the examination before the joint medical and surgical board, the candidate shall become a member of the College of Surgeons, and acquire in virtue of his membership the right of access to the library of that College, and to the Hunterian Museum; together with the right of using the title of surgeon, and of being appointed to surgical offices, in public institutions, as heretofore.

It appeared, therefore, to the deputation that the important object was attained, that every future general practitioner should possess both a medical and surgical qualification, while, at the same time, the connection of the general practitioners with the College of Surgeons was also provided for.

Believing that it is essential for the maintenance of a high standard of qualification for the general practitioners, that their controul over the education and examination of their own class should be exercised as independently as possible of any interference on the part of the other branches of the profession, the deputation are of opinion, after much reflection on the subject, that if, in addition to the examination of the general practitioner by his own college, an examination by a joint board of physicians and surgeons is insisted upon by the government, and if such examination is to be interposed, at some period, between the completion of his education and his acquiring the title to registration, it will be desirable that such examination should follow, rather than precede, the examination of his own college. If this order of examination be observed, the general practitioner will be educated under the direction of his own college; upon the completion of his education, he will present himself for examination before his own college, and will not be admissible to the examination by the joint medical and surgical board, until he has succeeded in satisfying his own college of his competency to practise every branch of his profession. The College of General Practitioners will thus be enabled to ascertain whether the standard of qualification, which it has itself fixed, has been attained, and will be left to exercise its functions as an examining body, freely and independently, and without the risk of having its judgment influenced, if not virtually anticipated, by the decision of a previous examining board.

On those grounds, therefore, the deputation were willing to assent to the proposed modification of the arrangement, as regards the order of the examinations, in the full hope that their assent to this modification would have enabled the Secretary of State to have perfected his measure during the present session of Parliament—a result which all, who are acquainted with the evils consequent upon the protracted discussion of a question like the present, would unite in desiring; and it is, therefore, not without regret that the deputation have seen the postponement of the measure to another session.

The interval, however, before the next meeting of Parliament will afford an opportunity of more maturely considering the question in all its bearings, and of profiting by any suggestions which may be made for rendering the arrangement, as a whole, as perfect as possible as regards the public, and as satisfactory to the great body of general practitioners, as with a due regard to the claims of the existing medical institutions of the country it can be made.

In concluding their report, the deputation beg to state that by the arrangement, as now modified, the station and attainments of the future general practitioner will, in the opinion of the deputation, be fully and effectually secured. He will go forth to the public with his professional competency attested by all classes of his profession, by physicians, surgeons, and general practitioners; and, thus accredited, he will possess the most complete and satisfactory evidence of qualification which could be required from him by others, and the strongest claims on the confidence of the public which he could desire for himself.

OBITUARY.—At Dublin, on the 30th of July, John Houston, M.D., in the 44th year of his age.

NATIONAL ASSOCIATION OF GENERAL PRACTITIONERS.

A full meeting of the Committee was held on Wednesday, in which, we are glad to say, the very best spirit of cordial good feeling and unanimity reigned. A very voluminous address was read, which was unanimously agreed on, and which will be ready for any applicants, by post or otherwise, in the course of a day or two.

The report thus concludes:—

"If, on the other hand, opposing parties unite their efforts and employ the facilities of communicating with the government which they enjoy, and the influence they possess with the government, for the purpose of inducing it to curtail the powers and privileges of the new Royal College, and in the spirit of corporate jealousy, without regard to the true interests of the profession and of the public, to impair its utility, efficiency, and respectability, if they defeat every effort to amalgamate the profession except upon terms so degrading as to render them impossible to be acceded to, then will it become the duty of the National Association to extend the sphere of its operations—to compass anew the whole question of medical reform, and to stand boldly forward on the broad principle of the public good as the opponent of the existing institutions. The committee would regard the conflict which this must lead to as greatly to be deplored. They are aware that it might be of years' duration, and none know better than themselves the personal sacrifices which must be made. But they have such confidence, engendered by the events of the year last past, in the public spirit of the medical profession, as to feel the most perfect assurance that, so soon as the deep sense of imperative duty becomes the impelling agent, their professional brethren will act as one harmonious whole, and employ their united exertions with the most enduring perseverance to obtain a FACULTY OF MEDICINE, without regard to the interests of those colleges which, by the aid of corporate privileges, conferred upon them in the comparative infancy of man's civilisation, have opposed themselves to the changes and ameliorations, which become essentially necessary as time wears on; and have thus, by retarding the progress of the healing art, and preventing the diffusion of scientific knowledge among its professors, shown themselves totally regardless of the miseries and mortality of their fellow-creatures."

The following remarks are appended:—

"There can be no doubt that the organisation of the general practitioners has become a subject of alarm in various quarters. Their number, respectability, education, resources, and the hold they have upon the public, are sufficient to occasion this. The most strenuous efforts have been made to break them up as a collective body, and to destroy their conformity of opinion and unity of action. Their professed friends have been employed as engines to effect this purpose. Happily, so far they have not succeeded. It will be observed that several circumstances relating to medical reform are adverted to in this day's transactions perhaps for the first time, having, in the discussion of the question, been purposely withheld from the professional eye, by those who had an object in wilfully misleading the profession. The sole object of the committee is the public good, and they have no doubt that the most direct means of advancing it is the general diffusion of the TRUTH. It remains to be seen whether the profession will maintain and strengthen its present organisation—if so, the committee will use its best efforts to complete it during the recess, and will remain firm in the discharge of their duty as respects themselves, their professional brethren, and the public."

Our notice must conclude with the following report of the resolutions:—

"The other matter prepared by the secretary for the Transactions, in accordance with a resolution of the special meeting of the 6th of August, having been read,

"It was moved by W. Smith, Esq., seconded by E. Baker, Esq., and carried unanimously—'That

the next number of Transactions do also comprise the matter now presented by the secretaries, and that the sub-committee be authorised to publish it forthwith with such verbal corrections as they may deem necessary.'

"Edward Headland, Esq., stated that he wished, before the Transactions were published, to call the attention of the committee to the measure now before Parliament for promoting the "Health of Towns," so that the members of the association might be assured that the interests of the general practitioners, so far as that measure was concerned, would not be overlooked by the committee.

"Moved by J. Merriman, Esq., seconded by H. P. Fuller, Esq., and carried unanimously—'That the sub-committee be empowered to authorise the treasurers to draw on the funds of the association for such amounts from time to time as may be required to meet the necessary current expences.

"Moved by J. Probert, Esq., seconded by H. Richards, Esq., and carried unanimously—'That although there is much reason to be gratified with the voluntary character of the donations to the funds of the association which have been subscribed in the absence of all the ordinary methods for obtaining such aid, the committee feel it their duty to remind the members of the association that the claims on its resources are necessarily very large, and that, as the strenuous exertions of the association will be required during the ensuing session of Parliament, it is highly important that the committee should be furnished with adequate means for all the purposes of the association.

"Moved by J. Bird, Esq., Hon. Sec., seconded by H. Ancell, Esq., Hon. Sec., and carried unanimously—'That the committee desire at the close of the present session of Parliament, and previous to adjourning their own sittings for the recess, to express the obligation under which they feel to certain portions of the daily and medical press, for their most efficient advocacy of the cause of medical reform, and particularly their sense of the talent and zeal with which the interests of the general practitioners have been advocated in the pages of THE MEDICAL TIMES.'"

"Moved by T. Paget, Esq., of Leicester, seconded by J. Lavies, Esq., and carried unanimously—'That honorary local secretaries being required in several county towns and boroughs, the sub-committee be requested to take steps for the purpose of obtaining the appointment of such functionaries by the members of the association resident in the respective localities, and be authorised to confirm such appointments.'

"Moved by J. Lavies, Esq., seconded by J. Merriman, Esq., and carried unanimously—'That the thanks of this committee are justly due, and are hereby given, to the sub-committee for their zealous and most valuable labours up to the present time.'

"Moved by N. Clifton, Esq., seconded by G. J. Squibb, Esq., and carried unanimously—'That the committee desire to express their most grateful acknowledgments to the respected chairman for his constant attention to the business of the committee, and his uniform courtesy while presiding over their deliberations.'

"Adjourned to the last Wednesday in October, unless specially summoned."

THE UNIVERSITY OF EDINBURGH AS A MEDICAL SCHOOL IN 1845.

At this the challenger with fierce defy
His trumpet sounds; the challenged makes reply;
With clangor rings the field, resounds the vaulted sky.

(To the Editor of the Medical Times.)

SIR,—It appears my classical friend, Mr. Deane, of Chatteris, is mistaken. The admission of a second letter from O. P. Q. into the *Medical Times* of this day proves that "Homer has not been caught nodding," but is wide awake, and occupies rather the position which was assumed by Prince John in a less worthy cause, when Waldemar Fitzurse exclaims, "Silence, Sirs, and let the Prince assume his seat. The knights and spectators are alike impatient, the time advances, and highly fit it is that the sports should commence." You take a perfectly legitimate position, Sir; you are disposed to give "a fair field and no favour," despite the gag which a certain pseudo-stickler for the "liberty of the press" would have placed upon you. In so doing you are following the course of an independent journalist, which you have ever done.

It is true, as Dr. Lewins observes, that "there is scarcely any subject can be discussed in a medical publication more vitally important to the public than that of the merits of medical schools, and there never was an epoch in the history of our profession when it could be more appropriately done than at the present moment." And now that the tournament is to be fought, your readers will look on, as deeply interested spectators. Success be to him who holds the right—only, as in former days, the knights of chivalry were bound by laws of honour to avoid all unfair weapons on the tilt, so let the combatants on the present occasion disuse all such words as "humbug," "fat-headed blockheads," "diploma-shops," "cowardly sycophants," "miscreant." Such terms sound harsh to "ears polite," and produce upon our intellectual sensation a feeling more unpleasant than that which a blow on the ulnar nerve conveys to our little finger. Many a cause has been injured by rough words: hence arises the pleasure with which we turn from the uncouthly and roughly expressed writings of a Luther or an Eck, to the elegantly and smoothly written, but not less powerful, productions of an Augustine or a Melancthon.

As to the system of patronage, whether in Scotland or at Guy's, St. Thomas's, St. Bartholomew's, or any other sainted or unsainted institution, the sooner it is uprooted the better. Rehoboam was the son of Solomon, yet he walked not in his father's steps. I often wonder—we are so willing to have our vocabularies supplied with French words, and our fashion books with French "cuts" for ourselves and our female friends—how it is we do not display the same love for the French concours. I like a good thing, whether it come from France or Lapland, from London, Edinburgh, or Heidelberg. Let the Parisian tailors keep their newest cuts at home if they choose; and give me a knowledge of the words of our Saxon progenitors; but let us have the concours, or something like it, in the election of medical officers to "high places." We should then have our physiologist Turner, of Manchester, wrestling with Todd and Bowman, and Hall, and others, of the metropolis; our ovariotomist, Clay, with Key and Phillips, and others; our oculist, Walker, with Guthrie, and Morgan, and Travers, and others; our lithotomist, Wilson, with Green and others; our Bardsley, Noble, Roberton, Hunt, and Heath, and Radford, each in his own sphere asserting his intellectual and scientific prowess; and there being none to favour or to frown, talent and intellect and industry would meet with their reward and their due meed of praise. Patronage, for aught I know, may be a blessing in the courts of princes, but it is a curse and a bane to science. Down with it! Then competent persons will be sure to exist within the walls of the colleges, and such discussions as that now pending on the "University of Edinburgh" will be rendered unnecessary.

I am, Sir,
Yours respectfully,
A. W. C.

Grosvenor-street, Manchester,
Aug. 2, 1845.

THE RECENT ADVERTISEMENT FOR A MEDICAL COMPANION.

[On the subject of our leading article of three weeks since, we have received from the advertiser the following explanation.]

(To the Editor of the Medical Times.)

SIR,—The simple facts of the case are these: a nervous invalid of whom I have the care, and who is residing at the house of a professional friend of mine, has for the last six months been attended by a man servant during his walks and rides, and in making his toilet—he also *shaved* him.

He has lately so much improved in health, that it was thought desirable he should have a companion instead of a servant, who would have been considered in all respects his equal, and as the advertisement stated, "be treated as a gentleman," with the exception unfortunately of being required to shave him.

For this he was offered his board and lodging, and £50 per annum, equal in fact to £100, for less than which nine-tenths of the curates of England (who must be admitted to be at least equal to himself) are obliged to subsist.

These very aristocratic gentlemen, our present assistants, for whom you have been pleased to take up the cudgels, can, it seems, be content to stand behind a counter from morning to night, can administer a clyster, or apply leeches when required, for little more than half the sum, but then they would not have to soil their fingers with a shaving-brush.

But, Sir, I beg to remind both you and them, that to them the advertisement was not addressed, inasmuch as, in the first place, it was addressed to men of middle age, and in the second, it was expressly stated that "Membership of the College or Hall was not required." Now, Sir, you know as well as I, that there are too many in the profession so situated, who are doomed to drag on a weary and ill-paid servitude, who would consider the offer I made a paradise comparatively speaking, and to such I addressed myself.

God forbid, Sir, that I should be thought capable of undervaluing the services of any professional brother, but in the present instance, I am not not only wholly guiltless of such an intention, but really in my simplicity considered I was doing them a service, as the situation might be equally well filled by any one else, as by a medical man.

We each of us have our own opinion as to what may be considered degrading; for my own part, I consider nothing such that is not dishonourable, and, were I wanting bread, and refused such a situation merely because I should have to shave a man, I should feel that I richly deserved to starve.

I am, Sir,
Your obedient servant,
ALPHA.

July 28, 1845.

BRITISH MEDICAL SCIENCE IN DAMASCUS.

To the Editor of the Medical Times.

DEAR SIR,—I am favoured with the file of the *Medical Times* through my friend Dr. Hodgkin, which he says you were kind enough to supply to us at this remote quarter of the world, and for which please accept my grateful thanks. You will be pleased to hear that my labours here have been very successful; the number relieved up to this date is over 7,000, of all sects, classes, and colours. I visit the *harems* of the most fanatical Turks and Moslems, and attend the Pasha and all the official personages; latterly, I am consulted a good deal on the diseases of females, which, considering their natural habits of seclusion, is a great privilege, and one of the best proofs of how soon and efficiently I have overcome the prejudices of the inhabitants of one of the most fanatical cities, and the stronghold of Moslem bigotry in the East. The cases of insanity are now discharged cured, and the cases operated upon have proved successful. Our summer is set in very early; thermometer at midday from 88° to 92° in the shade, falling 15° and 20° at night and morning. The sickly months are July and August; sometimes the end of June and early part of September are sickly. The country is destroyed by locusts, and the people always anticipate distress and disease when these make their appearance in such swarms.

With many thanks, I am yours, very truly,
JAMES B. THOMPSON, A.B., M.D.,
Chief Medical Officer.

British Hospital, Damascus, July 9, 1845.

A SELECT PRACTICAL FORMULARY.

Translated from the French of M. Foy, Principal Pharmacien to the Hospital Saint Louis, at Paris.

(Continued from page 232.)

SAMBUCUS NIGRA (flowers).—Infusion, half a drachm to two drachms to a quart of boiling water; distilled water, one to three ounces, as the vehicle of a potion or mixture; extract (formerly called ROB), one to three drachms in bolus or pill, or in solution in an appropriate menstruum; extract of

the inner bark, thirty to forty grains as a purgative. The juice of the same part of the elder is equally purgative, in the dose of from two to three spoonsful; it is given in milk. The elder, especially the flowers, is a stimulant diaphoretic in the treatment of rheumatism, gout, and all cutaneous affections. The juice of the elder-root has been given with some success as a purgative in dropsy, ascites, in the dose of from two to four, six, and eight ounces in the course of the day. Used externally in lotions, injections, discutient fomentations, in the dose of from one to three drachms to a pint of water.

SOLUTION OF CAMERON (English formula).—Eight ounces of nitrate of potash, fifty-two ounces of vinegar, sugar ad libitum, and a few drops of the essential oil of mint. Mode of exhibition, three to eight ounces daily. Used in cases of scurvy.

SOLUTION, ALCOHOLISED, OF THE CHLORURET OF LIME (Chevalier).—Three drachms of the dry powdered chloruret of lime, dissolved in two ounces of distilled water, the solution filtered, and two ounces of alcohol at 36°, and a few drops of the essential oil of cloves added. Mode of exhibition: A coffeespoonful in a glass of water, to wash the mouth and gums with the aid of a sponge-brush. *.* This solution is of service in removing the smell of tobacco-smoke, and also in the form of lotion in cases of ramollissement of the gums, with fetid ulcerations.

SOLUTION OF CITRATE OF MORPHIA (Magendie). —See ROSE DROPS.

SOLUTION, CONCENTRATED, OF CORROSIVE SUBLIMATE (Renaud).—Twenty grains of corrosive sublimate dissolved in one ounce of distilled water. Used to cauterise surfaces previously denuded by a blister, in the treatment of buboes, &c.

SOLUTION OF THE CHLORURET OF LIME.—Three ounces of the chloruret of lime, dissolved in a pint of distilled water. Used in lotions in the treatment of the itch.

SOLUTION, CUPRO-ARSENIOUS (Form. Hosp. Milit.).—See Lanfranc's Collyrium.

SOLUTION, CYANURETTED (Parent and Boutigny). —A solution containing from six to ten grains of the cyanuret of mercury to the pint of distilled water. Mode of exhibition: One to two drachms daily in an appropriate menstruum. Used in the treatment of syphilis.

SOLUTION OF THE CYANURET OF POTASSIUM (Lombard of Geneva).—A solution containing from one to four grains of cyanuret of potassium to the ounce of distilled water. Mode of exhibition: In lotions, in cases of facial neuralgia.

SOLUTION OF THE CYANURET OF POTASSIUM (Magendie).—See Medicinal Hydrocyanate of Potass.

SOLUTION, DIURETIC (Martin-Solon).—Twenty grains of recent digitalis, forty grains of white sugar, triturated together, and poured into a quart of pure water and two ounces of simple syrup. Mode of exhibition: By small cupsful in the course of the day, in affections of the heart.

SOLUTION, ETHEREAL, OF THE DEUTO-IODURET OF MERCURY (Magendie).—A solution containing twenty grains of the deuto-ioduret of mercury in the ounce and a half of sulphuric ether. Mode of exhibition: Ten to twenty drops and more progressively, in a glassful of *eau sucrée*.

SOLUTION, FOWLER'S.—See Fowler's Arsenical Liquor.

SOLUTION OF THE HYDRIODATE OF POTASH (Magendie).—A solution containing thirty-six grains of the hydriodate of potash in the ounce of distilled water. Mode of exhibition: Ten to twenty drops daily in an appropriate menstruum. Used in the treatment of bronchocele, scrofula, &c.

SOLUTION, IODURETTED, OF THE HYDRIODATE OF POTASH (Coindet).—The preceding solution, with ten grains of iodine in addition. Mode of exhibition: Five, ten, and fifteen drops three times a-day, in a little *eau sucrée*. Used in the same cases as the preceding solution.

SOLUTION OF HYDROCHLORATE OF MORPHIA (English hospital).—A solution containing one grain of the hydrochlorate of morphia in 100 drops of distilled water. Mode of exhibition: Ten to twenty-five drops in a mixture, potion, or julep, as a sedative.

SOLUTION, CAUSTIC, OF IODINE (Puche).—Rectified alcohol containing as much iodine as it can hold in solution. Used the same as the iodurctted solutions.

SOLUTION OF THE IODHYDRARGYRATE OF THE IODURET OF POTASSIUM (Puche).—Eight grains of the deuto-ioduret of mercury, eight grains of the ioduret of potassium, dissolved in eight ounces of distilled water. Mode of exhibition: Two to eight drachms in the same cases as the pills of the iohydrargyrate. Externally: First, in the form of gargle, in cases of ulcerations of the throat; secondly, in injections in chancres, affecting either the canal of the urethra, the vagina, or neck of the uterus; and thirdly, in lotions, to cleanse chancres of the penis, atrophy, flat tubercles, &c.

SOLUTIONS, IODURETTED (Lugol).—These solutions, which are intended for external use, are prepared thus: No. 1, with two grains of iodine, four grains of ioduret of potassium, and a pint of distilled water; No. 2, with three grains of iodine, six grains of ioduret of potassium, and a pint of distilled water; No. 3, with four grains of iodine, eight grains of ioduret of potassium, and the same quantity of distilled water. Mode of exhibition: In lotions, collyria, or fomentations, in scrofulous affections, and in injections into fistulous canals, into the nasal fossa, &c.

SOLUTIONS, CAUSTIC IODURETTED (Lugol).—Three drachms of iodine, three drachms of the ioduret of potassium, dissolved in six drachms of distilled water. Mode of exhibition: As the preceding, when the next preparation becomes inactive.

SOLUTION, RUBEFACIENT IODURETTED (Lugol). —One drachm of iodine, two drachms of ioduret of potassium, dissolved in an ounce and a half of pure water in a glass mortar. Mode of exhibition: Dip a small brush in this solution, and touch with it the parts affected with scrofulous ulcers. This solution keeps down the granulations, stimulates their surface, and consolidates the cicatrices.

SOLUTION OF LAUDANUM (Cullerier).—One to two ounces of liquid laudanum, one quart of pure water, mixed together. Used in the same manner as the opiate solutions.

SOLUTION, OPIATE MERCURIAL.—Eighteen to seventy-two grains of the deuto-chloruret of mercury, dissolved in a pint of distilled water, to which is added from half an ounce to an ounce of Sydenham's liquid laudanum. Mode of exhibition: As a topical application to indolent and stationary venereal ulcers, by means of pledgets of lint soaked in it; also in lotions, more or less frequently repeated, on obstinate pustules; as also on inveterate tetters, whether they be or be not connected with a syphilitic virus.

SOLUTION, MERCURIO-IODURETTED (Biett).—A solution containing one grain of the proto-ioduret of mercury in two drachms of honey of roses. Mode of exhibition: Applied on ulcerations of the mucous membrane of the throat by means of a small brush.

SOLUTION OF THE HYDROCHLORATE OF BARYTES.—A solution containing one drachm of the hydrochlorate of barytes in five drachms of pure water. Mode of exhibition: Internally; ten to twenty drops for children, twenty, thirty, to sixty drops for adults, in a mucilaginous drink, as an anti-scrofulous medicine. Externally, in lotions on ulcers and tetters, and to remove specks of the cornea.

SOLUTIONS OF THE NITRATE OF SILVER.—The weak solutions contain from half a grain to two grains of the nitrate of silver to the ounce of distilled water; the strong solutions, from four to six grains, and those called concentrated, from eight to ten grains for the same quantity of liquid.

The first are employed in the treatment of certain ophthalmiæ, whether acute or chronic, in blenorrhagia, fistulous canals, &c. In the first case, a few drops (two or three) are instilled evening and morning between the eyelids, either with a feather or in any other way; in the second and third, they are used in the form of injections.

The strong solutions are used in dressing fungous and callous ulcers, wounds, burns, &c., which it is desirable to stimulate in order to hasten cicatrisation. All that is requisite is to dress the parts with lint sprinkled with the solution, and to repeat the dressing every twenty-four hours.

The third, or concentrated solutions, are intended to be employed in certain cases of aphonia; a sponge wetted with the saturated solution is placed at the back of the throat, and on the upper part of the larynx.

SOLUTION OF NUX VOMICA (Schwartz).—Eight to sixteen grains of the alcoholic extract of nux vomica dissolved in one ounce of distilled water. Mode of exhibition: Five to six drops for very young children, twelve to fifteen for older children, and from twenty to fifty drops for adults. This solution may be taken in a little *eau sucrée*. Used in cases of prolapsus recti and incontinence of urine.

SOLUTION, OPHTHALMIC (Sichel).—Thirty-six grains of the hydrochlorate of barytes, one ounce of distilled water. Mode of exhibition: Six to forty drops four times a-day, in a glass of *eau sucrée*, in the treatment of scrofulous ophthalmia.

GOSSIP.

ROYAL COLLEGE OF SURGEONS.—Gentlemen admitted Members on Monday, July 28, 1845:—J. Harris, J. Elliott, G. Pratt, S. C. Nelson, G. Turner, E. Jotham, W. Locke, H. Pitt. Admitted, August 1:—E. B. Batten, A. Hoskins, H. E. Nankivell, G. Bullen, R. Hopwood, B. Sykes, J. Whicker, O'C. D'Arcy, E. Lowdell, W. Docker, J. H. Osborne, J. C. Day. Admitted, Monday, August 4:—J. H. Worrall, J. W. Meeson, A. Jackson, G. Brown, F. A. Kingdon, F. Hatchard, S. Ross. Admitted, Friday, August 8:—W. Wadham, F. Whitborn, J. E. Snow, H. J. G. Young, R. T. Fletcher, J. M'Craith.

APOTHECARIES' HALL. — Gentlemen admitted Licentiates on the 7th of August, 1845:—George Allen, Hammatt Hailey, Joseph Clement, John Clay, William Lightfoot, Michael Anthony.

At the *close* of the session, after twenty years of tricky nonsense, the order-paper of the House of Commons contains a long notice of a bill on medical reform from that notorious Marplot of good medical legislation, Mr. Wakley. It is needless to say that the manœuvre is transparent, and that this attempt to hoax medical men and the public will be no more successful than the mock project of a College of Medicine, the hollow support of a British Medical Association, the grand bubble of a Medical Protection Assembly, and equally deceptive scheme of an Aggregate Meeting and Breakfast.

MORTALITY TABLE,

For the week ending August 2, 1845.

Causes of Death.	Total.	Average of 5 summers	Average of 5 years

No. 309. SUMMARY. Aug. 23.

CLINICAL LECTURES ON SURGERY.

BY M. F. LALLEMAND.

Translated for the Medical Times by JOHN WATERS, M.D. M. R. C. S. E., Ancien Eleve des Hôpitaux, Membre de la Société des Medecins Etrangers, &c. &c.

Blenorrhagia —Venereal Affections — Syphilitic Blenorrhagia.—Cases.—All causes capable of irritating the urethral mucous membrane may occasion urethritis, the intensity of which is in relation to the activity of the morbific agent and the susceptibility of the mucous surfaces. Thus, long journeys in carriages, severe horse exercise, masturbation, venereal excesses, the abuse of certain liquors, &c., frequently determine an increased secretion of the urethral mucous membrane, and particularly of its follicles. In all these cases, the action of the determining cause is too clear to occasion any confusion in the diagnosis. When the discharge comes on after sexual intercourse, either during the catamenial period, or under a leucorrhœal influence, or a dartrous affection of the vagina, &c., the existence of a contagious virus may be suspected; but if the discharge is not communicable afterwards, there exists but an inflammation of the mucous follicles of the urethra and prostate, more or less severe, accompanied with an ulceration, and an ncrease of their secretion. Again, an idiosyncracy, the sudden disappearance of an exantheme, the length or narrowness of the prepuce, the accumulation of sebaceous matter between the prepuce and the glans, &c., may occasion urethritis in one person, whilst in another (cohabiting with the same woman, at the same period) nothing is felt. All these discharges ought to be designated under the name of "blenorrhœa," while the term "blenorrhagia" should be given to those which result from a direct impression of a special virus on the mucous membrane of the urethra—a virus which is contagious, and which acts always in the same manner on all mucous membranes where it may be placed. It is not necessary to say more about these two species of discharges, for they are at present generally understood.

It happens sometimes that blenorrhagia continues, notwithstanding every means employed to arrest it, and can only be cured by the administration of an antivenereal treatment; sometimes existing simultaneously with other venereal affections, when its character cannot be doubted. On the other hand, discharges which do not sensibly differ from ordinary blenorrhagias, are followed frequently, after a period more or less long, by various secondary symptoms, perfectly like those of constitutional syphilis, although there existed neither chancres nor buboes in the commencement. Again, in some cases, where the symptoms were those of constitutional syphilis—viz. exostoses, periostoses, and even buboes—when these have suddenly disappeared, they are replaced by copious discharges; and these require for their recovery a complete antivenereal treatment. In all these cases, we must admit another cause, besides that which produces an ordinary blenorrhagic discharge; we must admit the existence of a syphilitic virus. These two contagious principles differ one from the other; inasmuch as the blenorrhagic virus is not susceptible of being transmitted by inoculation, affects only mucous membranes, and produces discharges only. The syphilitic virus, on the contrary, admits of inoculation, can be transmitted by every means of absorption, and consecutively affects all the tissues of the economy, by producing various alterations, which are of a specific nature, and which require a special medication. It is because this distinction had not been established in a rigorous and conclusive manner, that the question was so long agitated, whether all blenorrhagic contagions were syphilitic or not. Hence the numerous imaginative theories to explain on one hypothesis two different things. The practitioners, whose attentions were occupied with the nature of blenorrhagia, were generally too exclusive. There are, I repeat, blenorrhagic discharges, which only produce blenorrhagia, and these constitute the majority of these affections; but there are, incontestably, syphilitic blenorrhagiæ, as we shall also point out. Formerly, all urethral discharges were attributed to ulcerations in the canal of the urethra, but, in later times, with post-mortem researches more in use, when attention was extended to the state of the urethra after an attack of blenorrhagia, the absence of these supposed ulcerations was occasionally proved, even in subjects who had died suffering under the severest forms of blenorrhagia; and it is demonstrated that, in this affection, there is never ulceration of the canal. Morgagni took up the question. In his numerous experiments, he recognised, in the interior of the urethra, as the consequence of *syphilitic* blenorrhagia, bands, valves, true cicatrices, which he attributed to the existence of ancient ulcerations, which became cicatrised from the centre towards the circumference. This great anatomist remarked the frequency of these disorders at the prostatic portion of the urethra, and observed a certain turning backwards of the ejaculatory canals, in cases where the cicatrix had formed between the orifices of these canals and the neck of the bladder. Other anatomists have since proved the same fact. We cannot doubt the existence of these ulcerations in certain cases of blenorrhagia (the syphilitic), if we bear in mind what happens during life. Who has not seen, at the orifice of the glans, or in separating the lips of the meatus urinarius, one or two isolated venereal ulcers, with everted edges, and of a grayish aspect? If the infection extends into the interior of the canal, or if it be confined to the meatus urinarius, it will determine in these points the same alterations, and, at the same time, it will induce a more or less abundant discharge. These ulcerations in the urethra are easily diagnosed, even when they are out of sight; they are characterised by a sharp, lancinating pain, at the time when the urine passes over a fixed point in the urethra; this feeling of heat is compared by the patient to the cutting of a knife. The urine contains small vermiform filaments, or it is streaked with blood, sometimes even with clots, which appear to be given off from the altered surface; even rather large hemorrhages have been seen under similar circumstances. Sometimes, when a patient wishes to empty the bladder, the penis swells, and becomes nearly erect, and the urinary canal is narrowed, so as suddenly to arrest micturition. If, after these accidents, it is supposed that there is an urethral stricture, and catheterism be tried, it produces an extremely sharp pain in a fixed point of the canal, and the prolonged contact of the catheter becomes insupportable. But it may be said, that these ulcerations are only simple excoriations of the mucous membrane of the urethra, since, in some cases, the discharge disappears by the sole use of antiphlogistics, or even spontaneously, if the affection has assumed a chronic form. The reply to this objection is, to take into consideration what takes place *exteriorly*. Every surgeon knows that many primitive venereal ulcers become cicatrised in the same way, under the influence of an antiphlogistic or emollient treatment, and with common attention to cleanliness; and it is facts of this kind that have served as an argument to some novices in support of their idea that syphilis is only an ordinary inflammation. It is not, however, always easy to diagnose in a precise manner the existence of an internal ulcer. Patients do not always feel the symptoms just related, or the symptoms are removed before the attention is called to them. It is not, however, necessary to admit an ulceration of the canal to understand the syphilitic nature of these discharges. Chancres, buboes, pustules, &c., in a word, all the primitive symptoms, do not appear till many days after infection; they are, therefore, the *consequence*, not the *cause*. The fact that some buboes come on without either a chancre or a discharge, is, in itself, sufficient proof. Why could not the venereal virus, acting on the mucous membrane of the urethra, produce a discharge without ulceration? Why could not these blenorrhagias preserve their venereal character? It is this fact which points out to us the discharge which is accompanied with chancres, when the other symptoms of internal ulceration are absent. The treatment should, in these cases, be not for the blenorrhagic, but for the syphilitic symptoms, and the discharge will disappear with the syphilis. If people had drawn from all these facts the consequences which naturally flow from them, the question would have been settled long ago. After an attack of blenorrhagia, therefore, if there should be consecutive symptoms which induce the suspicion that there was a venereal *cause*, the treatment should be directed accordingly, and the symptoms will soon disappear. We must bear in mind these facts, so as not to reject an antivenereal treatment in these doubtful cases, under the supposition that the patient never had but an ordinary discharge. A few striking examples will clear up these generalities. Two soldiers came to the hospital, one with chancres, the other with a blenorrhagia, which they had contracted the same day and with the same woman. Being put under the same treatment (bichloride of mercury), they were rapidly cured. An officer was affected with a discharge which resisted, during three months, the usual remedies; he happened to relate the circumstances of his case to a student, who knew the woman that caused the infection, and who was then in the hospital at Montpellier, with chancres at the bottom of the vagina and around the cervix uteri, accompanied with a profuse discharge. The blenor-

rhagia contracted by this officer was, consequently, considered syphilitic; antivenereals were administered, and he rapidly recovered. When the discharge is accompanied with venereal symptoms, or followed, after its disappearance, with consecutive syphilitic phenomena, the exciting cause cannot be doubted. A soldier, ætat. 32, who had several times suffered from blenorrhagia (which yielded to the antiphlogistic treatment), had chancres, which disappeared by cauterisation. Six years afterwards, at a period when the economy was still affected with syphilis, a fresh blenorrhagia was contracted, and yielded to the balsam of copaiva. The cessation of the discharge was followed by a bubo, which, in turn, terminated by resolution, under the influence of local bleedings and mercurial frictions. A year after, the patient came to Saint Eloi in the following state:—Pustules in the scalp, forehead, thorax, and back; excoriation of mucous membrane of the mouth; a copious urethral discharge, of a green colour, dating back for six months; obscure pains in the region of the prostate; painful erections. (Treatment, by mercurials and sudorifics.) At the end of two months, the discharge had completely disappeared, as well as the general symptoms. Here, again, we cannot doubt the syphilitic nature of these numerous discharges. On other occasions, we see, after a length of time, affections come on, which, at the first onset, do not appear to bear any relation to discharges contracted formerly. On tracing back, however, we find that a blenorrhagia had formerly existed, which had been cured by the ordinary means. Antivenereals are now administered, and the treatment is eminently successful.

CASE I.

Blenorrhagia: Twenty-three Years afterwards an Attack of Syphilitic Orchitis simulating Sarcocele —Antivenereal Treatment—Rapid Recovery.

In the month of January, 1844, a glazier, who came to my house to put in a pane of glass, took advantage of this circumstance to consult me. This man showed an enormous testicle, which ascended to the external ring, and at the first aspect resembled a sarcocele. There existed at the same time, and on the same side, an old inguinal hernia, and which would have complicated any operation that might have been tried to remove the tumour. It had a regular form, whereas in the cancerous degenerescences of the testicles the affected parts are unequal and in bumps. The patient had, twenty-three years ago, a simple discharge, without any other venereal symptom. He was attended by Dr. Christian, and continued to work without observing any particular regimen. These particulars, and the form of the testicle, induced me to consider the swelling as venereal; moreover, the presence of the hernia rendered the operation more serious. I did not wish to have recourse to this extreme before trying some other means. The patient insisted that he had not felt any venereal symptom for twenty-three years, that the affection of the testicle came on slowly, &c. Nevertheless, a specific treatment was put in force (bleeding, pills of Sedillot, iodide of potassium, sudorifics in high doses); in the space of three months the testicle had assumed its normal form and size. Here is a simple discharge, followed, after twenty-two years of perfect health, with a severe affection of the testicle, which disappeared rapidly under the influence of an antivenereal treatment. How doubt that this attack of blenorrhagia was syphilitic? Other cases of secondary symptoms, such as periostoses, exostoses, pustulæ, &c., sometimes disappear spontaneously, leaving, however, behind them a copious discharge, which will only yield to an antivenereal treatment, just as we sometimes see the sudden disparition of a dartrous affection followed by blenorrhœa.

En resumé. There are three species of urethral discharge. 1. Blenorrhœa, *not contagious*, resulting from an accidental irritation or inflammation of the mucous follicles of the canal, and particularly of the prostate. 2. *Contagious blenorrhagia*, caused by a particular virus, whose effects are purely local. 3. *Syphilitic blenorrhagia*, more uncommon than the others, followed by consecutive symptoms of a venereal nature, or succeeding to the primitive symptoms. Thus it was wrong to admit, in an absolute manner, that all blenorrhagic discharges are syphilitic, and again to reject, in as general a manner, the existence of syphilitic blenorrhagia. Consequently, when a discharge resists all our means of recovery, even cauterisation, we must put in force antivenereal treatment, when even there does not exist any special indication to go by. The absence of external symptoms is not sufficient to reject the idea of a venereal origin. The diagnosis will be evident at once when venereal symptoms have simultaneously existed, or other individuals have contracted chancres, buboes, &c., with the same women. In cases where blenorrhagia has assumed the symptoms of constitutional syphilis, the general infection should occupy the whole attention, and the discharge is to be neglected, except the intensity of the inflammation should require the use of antiphlogistics.

REPORTS ON DISEASES OF FEMALES.

By EDWARD RIGBY, M.D.

Fellow of the Royal College of Physicians, Senior Physician to the General Lying-in Hospital, Lecturer on Midwifery at St. Bartholomew's Hospital, Examiner on Midwifery to the University of London, &c.

(Continued from page 344.)

I have already shown that prolapsus uteri is a frequent accompaniment of leucorrhœa, especially of the simple form. I believe that it is now considered by most authorities on these subjects, that the uterus owes its chief support to the contracted state of the vagina, as shown by the corrugated state of its lining membrane in a healthy female, and that where this fails, the ligaments of the uterus do not suffice to retain it in its natural position.

It would be scarcely correct to call prolapsus uteri an *effect* of leucorrhœa, since they both arise from the same cause, viz., a relaxed and atonic condition of the vagina—the result of generally impaired health, although there is no doubt that the leucorrhœa, by enfeebling the system, increases the inability of the vagina to support the uterus, and aggravates the disposition to prolapsus; hence we find that this displacement is mostly preceded, as well as attended, by leucorrhœa.

Prolapsus uteri may be *partial* or *complete*—that is, the uterus may descend to a slight extent, so that its mouth will be found nearer to the os externum than usual, or it may pass entirely through the os externum, the whole mass protruding between the thighs of the patient. These two forms, which, it may be observed, vary only in degree, might almost be designated the first and second stages of the same complaint, because the uterus seldom remains partially prolapsed for any length of time, but sooner or later the prolapsus becomes complete. This will be readily understood if we consider what takes place in a slight degree of prolapsus. The broad ligaments are put upon the stretch, and the return of blood more or less impeded; the uterus swells, and grows heavier; the relaxed vagina is not only dilated by the increasing size of the uterus, but is less and less able to support its increasing weight. The further it descends the more it swells, and the increased dilatation of the vagina prepares it for a still further descent; thus cause and effect act and react upon each other, until at last every means of support has failed, and the uterus hangs from the os externum, forming a large fleshy mass many times larger and heavier than in its natural state.

Patients, as Richter observes, who labour under partial prolapsus suffer much inconvenience, partly from the pressure which the prolapsed uterus exerts upon the neighbouring parts, especially the bladder and rectum (considerable obstruction being produced in the evacuation of their contents, some patients having complete retention of urine, except when lying in the horizontal posture, and pressing up the uterus with their fingers), and partly from the tension and dragging of the parts which are connected with the uterus, producing much pain in the region of the loins. All these symptoms increase when the patient stands for some time, diminish when she assumes the horizontal posture, and disappear entirely when the uterus is returned into its natural position

As the uterine attachments gradually accommodate themselves to this state of tension and displacement, it will be easily understood why the symptoms are at first more severe, and afterwards gradually diminish, and also why they are more acute where the prolapsus comes on suddenly than where it takes place slowly. Where prolapsus is the result of violence suddenly applied, we occasionally see it followed by syncope, hemorrhage, fever, and inflammation. Prolapsus may also take place during pregnancy. When the uterus descends entirely out of the vagina, and thus becomes complete prolapsus, the symptoms which had arisen from the pressure of the uterus upon the neighbouring parts disappear; whereas those which arise from the uterine attachments, being violently stretched and distorted into an unnatural shape and position, become greatly aggravated.

As the cervix uteri descends, it draws down with it the upper part of the vagina which covers it. Where the whole uterus protrudes beyond the labia, it drags down the whole of the vagina, which thus becomes inverted, and covers its external surface. In this state the uterus is, as it were, suspended from the labia, nor is there any space between them, on either side, into which we can pass the finger or a probe. This can never happen without the rectum or bladder (from their intimate connection with the uterus) being dragged to a considerable extent out of their natural situation. The bladder is always turned backwards, so as to take the place of the uterus in the pelvis, and, with the urethra, lies in a horizontal position, so that, under these circumstances, the stream of urine is ejected in a horizontal direction, or even upwards; that when the catheter is required, which is frequently the case, it must be introduced backwards, in a horizontal direction towards the rectum.

The circulation being more and more impeded as the uterus descends, this continues to increase in size, so that when the prolapsus has become complete, the mass is not only many times larger and heavier than the unimpregnated uterus in its natural state, but has undergone more or less alteration in form; the distinction between the cervix and body of the uterus is entirely lost in the general swelling of the organ; the os uteri is larger than natural; its lips soft and tumid; while not unfrequently, owing to the congested circulation, occasional hemorrhage takes place from its cavity.

The outer surface of the prolapsed uterus is formed by the inner surface of the vagina, which, being attached to the os and cervix uteri, has been dragged down by the descent of these parts, and turned inside out. The mucous membrane, thus exposed to the air, dries, loses its red colour, and assumes the appearance of skin. At the upper and front part of the uterus the vagina has a looser and more rugous appearance, owing to a portion of the bladder being pressed down, and now lying between this part of the uterus and the vagina which covers it. It is the lower and back part of the bladder which, from its connection with the uterus, undergoes this displacement, so that the bladder becomes, as it were, retroverted, and, as before observed, either lies horizontally across the pelvis, or has its fundus even lower than the urethra. Hence we observe that the direction of the stream of urine is considerably altered, being horizontal, or rising in a jet upwards and forwards, and, in some aggravated cases, so completely upwards as even to wet the patient's abdomen. This circumstance should always be borne in mind when using the catheter, which, instead of passing in the usual direction, upwards and backwards, must be guided either directly backwards, or downwards and backwards. The prolapsed uterus is liable to be frequently wetted with the urine, which, together with the friction of the clothes, produces much irritation, and sometimes even ulceration of the inverted vagina which covers it

If the prolapsus comes on suddenly, as from over-exertion, external violence, &c., it is attended with very severe and formidable symptoms, not unlike those seen in sudden retroversion of the gravid womb, inversion immediately after delivery, &c. There is very acute pain, with sensation of dragging and tearing within the pelvis, vomiting, fluttering pulse, cold sweats, &c.

A partial prolapsus, and even the slighter degrees of complete prolapsus, diminish considerably when the patient lies down; it will be necessary to make an examination at a time when the characters of he displacement are most strongly marked. This

will usually be in the evening, when the prolapsus is at its worst; whereas in the morning, shortly before or after she has risen, it will scarcely be perceptible, especially if the bladder and rectum have not yet been emptied of their contents, as they tend to prop up the uterus, and prevent it from descending.

The chief characteristics upon vaginal examination are: the uterus with its os in advance, lower in the pelvis than natural, and the vagina more or less shortened. Having once ascertained these facts, the diagnosis is easy; indeed, it can only be mistaken for polypus, and *vice versâ*, and even here a very little care is sufficient to decide correctly. There is nothing like an os uteri at the lower end of the tumour in polypus; even if there be an orifice, it is ragged and uneven, and of no depth. The polypus is insensible; the vagina is not shortened as in prolapsus, and careful examination will generally detect the os uteri above, encircling the pedicle of it. A prolapsed uterus is reducible, and, with few exceptions, the reduction affords great relief; whereas polypus cannot be reduced, and every attempt to do so produces much suffering.

The diagnosis of complete prolapsus is self-evident.

The *causes* of prolapsus may be brought under two heads, viz., either those which produce relaxation in the parts destined to support the uterus, or those which act by forcibly driving the uterus out of its natural situation. Hence we observe prolapsus most frequently in women who have borne several children, and in whom the vagina has, therefore, been frequently exposed to the enormous dilatation requisite for the passage of the child's head. At no time, and under no circumstances, is it so liable to descend as shortly after labour; but the uterus itself is large and bulky. Thus it is very liable to occur in patients who have risen too soon after labour, before the soft parts had sufficiently contracted.

Another cause under this head is, as I have already stated, relaxation of the vagina consequent upon leucorrhœa. The vagina is relaxed, the uterus descends; this increases the discharge and general debility; the uterus swells, and grows heavy; it descends still further, and ultimately becomes completely prolapsed. Sometimes, however, where the perineum is broad, it will not pass through the os externum, but rests upon the perineum as upon a shelf, and descends no further.

The other causes are those which tend to force the uterus downwards out of its natural situation—as external violence, violent efforts of the abdominal muscles in straining, coughing, vomiting, lifting heavy weights, &c. These causes are the more certain of producing it when they are continually renewed and repeated, especially when the patient at the moment is in the upright posture, and particularly so shortly after labour. Thus it is why we observe prolapsus uteri so frequently among the lower classes, who are but too frequently obliged to get up and use active exertion, under circumstances when they should be enjoying a state of rest.

Prolapsus uteri sometimes, though rarely, takes place during the early months of pregnancy; whereas on the other hand, the uterus necessarily rises above the pelvis as it increases, and any disposition to prolapsus, which might at first have existed, disappears as pregnancy advances. Hence pregnancy is generally considered to be a natural cure of prolapsus, provided the patient maintains the recumbent posture for a sufficient time after labour.

The treatment of partial prolapsus consists in diminishing, as far as possible, the disposition of the uterus to force itself downwards, and in increasing the tonic contraction of the vagina, and in thus enabling it to support the uterus better. The first indication will be effected by rest in the horizontal posture, by brisk purgatives, which act chiefly by promoting the peristaltic action of the intestines, and thus diminish not only their bulk, but also the weight with which they press upon the uterus, and by a properly applied bandage for supporting the lower part of the abdomen. The other will be by regulating the functions of the chylopoietic organs, and improving the general strength and tone of the system—effects which we shall obtain by alterative and tonic medicines, cold bathing, sponging, shower bath, &c., and by astringent injections.

In complete prolapsus, after we have reduced the uterus to its natural position, the treatment will be essentially the same as in the partial form. In most cases the reduction is easy enough, if we grasp the uterus with the whole hand, and push it bodily upwards and backwards, and then, when it has attained a certain height, upwards and forwards. In some cases, however, it is so swollen as to resist any moderate efforts to reduce it; and even if we succeed, the presence of so large and solid a mass produces such inconvenience and suffering as to become intolerable to the patient, or even to be followed with inflammation and other dangerous consequences. Under these circumstances we must defer its replacement until we have reduced its size by leeches and the horizontal posture.

In attempting the reduction of complete prolapsus, where any degree of difficulty is expected, we should always direct the patient to have the bowels well evacuated, and to preserve the recumbent posture for at least twelve hours previous to our visit. This will generally diminish, if not the size, at least the hardness of the uterus sufficiently for our purpose; otherwise leeches must be applied, and even repeated, if necessary.

We occasionally meet with considerable ulcerations on the surface of a prolapsed uterus. Indeed, in severe cases, which have not been reduced for some time, they are more common than otherwise. They are generally situated about the lower portion of it, and are probably the result of excoriations, to which I have before alluded, aggravated by the congested and swollen condition of the uterus.

The presence of these ulcerations is no impediment to the reduction, because not only can we equally well apply any local treatment to the part, but now that the obstruction to the returning circulation from the uterus is removed, they quickly assume a healthier action, and rapidly heal of themselves.

Besides the means now described, a variety of mechanical supports have been devised for the purpose of preventing the descent of the uterus, the most common of which are pessaries. The different varieties of these are too well known to require description. I confess I cannot speak much in their favour, and have but rarely, if ever, used them in the numerous cases of prolapsus which have come before me in hospital practice. I would not willingly, or for slight reason, oppose a mode of treatment which has just been described, viz., the means for increasing the contraction of the vagina, and but too often produce the effect, of all others, which we should be most anxious to avoid, viz., the dilatation of the vagina. In moderate cases I think I may safely assert that they are *never* necessary. They appear, it is true, to succeed perfectly when applied, but I feel sure that the same degree of vaginal contraction which supports them so favourably would, with proper management, have sufficed to support the uterus without them. In severe cases they frequently require to have the size increased from time to time, until it becomes a source of much inconvenience, and sometimes mischief; and, after all, it is surely much more rational and practical to treat the case by removing the causes of the prolapsus, than merely to apply mechanical means for supporting the uterus.

The only form of pessary, if it can be called so, which I have used, is a cylinder of sponge soaked in an astringent lotion; but it is as much for the purpose of keeping the vagina in contact with the lotion as for supporting the uterus. Dr. Locock, as far as I am aware, has the merit of having first used a sponge in prolapsus uteri, although it was proposed by Osiander some time previously. The best mode of preparing it is to wrap it round the thick end of a piece of wood which tapers off like a common skewer, tying the end of the sponge firmly, so that the stick will not force its way through, and winding a piece of twine four or five times spirally round, to prevent its unfolding and altering in shape. It must be made so small as to pass easily up the vagina when soaked in the lotion; the stick prevents it from doubling upon itself and lying across the passage, and as soon as it is introduced to the full extent (the patient lying upon her back with the shoulders low), the stick is easily withdrawn and the sponge left in the vagina. It should be withdrawn twice in the twenty-four hours and thoroughly cleansed. As the contractile powers of the vagina increase, the size of the sponge requires to be gradually diminished, until the patient can dispense with it altogether. A T bandage applied tightly over the perineum and os externum will assist the sponge in being retained. I am well aware that with some patients this plan will not succeed; they will say that the sponge is forced down in spite of the bandage, &c. &c., but this is merely the result of their own awkwardness and neglect in not introducing the sponge as directed, and not taking the trouble to tighten the bandage from time to time as it gets loose.

For supporting the abdomen, I know of no instrument better adapted than Hall's "utero-abdominal supporter." I have frequently seen the uterus keep up merely by removing from it the pressure of the abdominal contents by means of this instrument. A well applied bandage, like those worn in advanced pregnancy, will also be found a useful means of giving support to the abdomen.

AN ESSAY ON THE VARIOUS FORMS OF ASPHYXIA, OR SUSPENSION OF SOME OF THE PRINCIPAL POWERS OF ANIMAL LIFE, WITH GENERAL RULES FOR RESUSCITATION.

By Dr. Chas. Clay, Piccadilly, Manchester.

(Continued from page 383.)

SYNCOPE.

Though not strictly asphyxia, so nearly resembles it, that it is necessary to speak of it in an essay of this nature.

It often happens that syncope assumes a very serious aspect when long continued, and, even with the best-directed efforts, restoration is often attended with great difficulty, and it is not unfrequently fatal.

General Causes.—Sudden diminution of the vital energies, arising from too great exertion; an erect position too long continued; exposure to extreme heat; violent emotions of the mind; disagreeable smells; disagreeable sights; derangements of the digestive organs; debility; excessive evacuations; disease of the heart and large blood-vessels; ossification of the valves of the heart, &c.

Syncope is too often looked upon as a commonplace matter, whereas it requires considerable exertions, and those well-directed, to accomplish the restoration.

Treatment.—The exciting cause should be removed immediately. The person in syncope should be laid immediately in a horizontal position, with the head a little raised; free admission of pure air; stimulants applied to the nostrils, so as to excite sneezing or coughing; a few drops of aromatic spirit of ammonia in a little water, given as drink; dashing the face and chest with a napkin dipped in cold water. These simple means will often be sufficient; but should the case assume a more serious aspect, remedies of a more determined character must be resorted to. If the person be of a full habit of body, it will be necessary to bleed; but if the cause of fainting be either from debility or hemorrhage, bleeding will be injurious. Inflation of the lungs with the bellows may be required in extreme cases, if real asphyxia be suspected, on the principles already laid down, substituting only a larger pair of bellows. If the cause arise from hemorrhage, transfusion of blood should be performed; but as this can only be done by medical men, a description of the means is unnecessary: it may, however, be proper to hint, that a very few ounces of healthy blood will restore life, though the previous loss may have been very great. Electricity and galvanism (subject to the same objections before stated) are necessary in extreme cases. Syncope from debility after long-standing disease, has, in many instances, been looked at as the approach of real death, and no efforts at restoration made, particularly when the disease has been one of a generally fatal character; this, perhaps, has been carried too far, and medical men would do well to direct their attention to this subject. Dr. Currie says—"In fainting, the heart immediately ceases to act with vigour, so that the blood which had undergone the necessary change in the lungs, and got into the left cavity of the heart and the vessels

belonging to it, remains there, and excites these parts to contract upon it, and push it onwards, as soon as they become sensible to its stimulus by the influence of the brain and nerves being restored. These circumstances explain to us why persons are more readily recovered from fainting than from the other causes of asphyxia; and also why there is seldom anything more required in this case than to rouse the nervous system by means of stimulants."

The stimulants most common and most easily procured are volatile salts, spirit of ammonia, ether, snuff, and spirituous liquors; for outward application, mustard, liniment with strong ammonia in it, friction, &c., &c. In applying means to the surface, care must be taken to prevent evaporation, as a contrary effect is often produced. Instead, therefore, of merely applying stimulants (that evaporate) to the skin, and allowing the part to remain bare, it is better to wet a cloth with it, apply it, keep it on the part, and spread a piece of bladder over it to prevent rapid evaporation. If stimulating fluids cannot be given by the mouth, it may be necessary to use injections to which some stimulant may be added, as a little warm wine, mint water, a few drops of laudanum, or a little brandy. In using such remedies it must be recollected that laudanum is to be added with great care, as it sometimes happens that a small dose has a very powerful effect on the system when given in clyster. I have seen it have a greater effect than larger doses by the mouth.

Laudanum in injections of starch, arrow root, &c., is particularly required when syncope arises from excessive purging. Excepting laudanum, the quantity of other stimulants used in injections is about double the dose that is generally given otherwise. Where transfusion of blood is called for, I think, if the patient be a female, female blood should be used; if a male, use the blood of the same sex, about the same age. The blood of animals has been used, that of the goat successfully, but I would not advise it, as human blood is always preferable and more easily at command. Exertions for restoration must not be given up too soon, as it is remarkable how long persons will lie in a state of syncope after violent muscular exertions, as in females after hysteric attacks, where circulation and respiration *appear* to be suspended for a very long time, and yet recover without even much trouble. In conclusion, great care must be taken to ascertain the cause; learn that distinctly, and half the victory is accomplished. There are some few *things not to be done*. These are—never bleed a weakly person, or where the syncope arises from excessive purging, hemorrhage, &c.; never crowd round the person—never omit bleeding a very plethoric habit—never practise your resuscitative operations in a close room:—use laudanum in injections with caution—in transfusion do not inject much blood, a little will answer, and never use the blood of animals if human blood can be obtained.

ASPHYXIA FROM HEMORRHAGE.

It is almost unnecessary to dwell upon this subject, as it forms a part of what has been said on general syncope; a few brief remarks, however, will not be out of place on this species of asphyxia, particularly on its

Cause.—Loss of blood producing immediate prostration of vital energy. This may arise from small bleedings frequently repeated, as in repeated nose bleedings, from long-continued bleeding from a small orifice, or from a sudden abstraction of blood from a large opening; where it is suddenly produced by abstraction from a large orifice, the quantity lost may not be near so great as in long-continued bleedings from small openings, and the danger is much greater in the latter case, as the system has been gradually drained of its vitality till little remains to build hopes of resuscitation upon.

General Remarks.—Apparent asphyxia arising from this cause is a frequent attendant on child-bearing, large operations in surgery, or accidents where large vessels are wounded, and is the principal danger in cases of cut throats. Asphyxia from small bleedings is frequently exemplified by the inability to stop the bleeding from leech-bites on children, nose-bleedings, and in some instances from tooth-drawing, of all which I have seen very many examples.

Treatment.—The first effort is to stop the hemorrhage, and it is truly astonishing how many lives are lost for want of a little common sense and presence of mind. If a person on seeing the blood spout out from a bleeding vessel, would coolly but determinedly press the tip of the finger firmly upon it, he would often effectually check the bleeding until a surgeon could be procured to take up the vessel; but generally any thing and every thing is done in such cases, *but what should be done.* In cut throats the wound should be closed and firmly held together until professional assistance can be procured.[1] In child-birth the main cause of hemorrhage is in consequence of want of contraction in the womb, or lesion of placental vessels, for which the general attendant should apply friction on the belly, bandages, and, in some cases, a plug of linen dipped in vinegar and water, placed in the natural passage, about four scruples of the ergot of rye given in decoction, and lastly, transfusion as before directed. Indeed, the principle is, and must be, to check the bleeding vessels as soon as possible, and then restore the patient, as in a case of common syncope. In small continued bleedings another line of practice comes under consideration; that is, where vessels are not required from their smallness to be tied, or where they are so situated that they cannot be secured by ligature. Under these circumstances, styptics, pressure, escharotics, &c., are to be depended upon. Hemorrhage from tooth-drawing is often very troublesome, and sometimes fatal; the vessel cut through retreats into the spongy cavity of the bone, and pours out blood freely and continuously. I have always succeeded in stopping this species of hemorrhage by making a short roll of lint, very hard, so as to fit the cavity formed by the extracted tooth, except that its upper end shall rise higher than the adjacent teeth; then, dipping it in the tincture of muriate of iron, and placing it in the space, shut the mouth, when the pressure from the opposite jaw effectually stops the hemorrhage. This plug is not to be removed for some hours. It will be observed this pressure forces some of the styptic tincture into the spongy texture of the bone, and so produces an effect on the mouth of the bleeding vessel itself. This styptic plug is also of great use in nose-bleedings, but it should be worn some hours; in severe cases, two or three days. A very novel way of stopping nose-bleedings has been proposed by a German, viz., closing the opposite nostril to that bleeding with one hand, and raising the other arm over the head, or pointing it directly upwards. Absurd and ridiculous as this may appear, I have seen it tried with success, but am at a loss to explain how it can produce such an effect; though it is explained, but not to my mind satisfactorily. In bleeding from leech bites, there is often some difficulty, as the animal often takes out a triangular portion of the skin. Dusting the bites with a flour dredger, and then applying pressure with the tip of the finger, will commonly succeed. Sometimes it is necessary to touch the bite with lunar caustic, or the styptic tincture of the muriate of iron. Cold wet pads will often succeed. In all cases of hemorrhage cool airy apartments are necessary, or else relapses will occur.

One or two things not to be done.—Do not leave the bleeding vessel until the hemorrhage is decidedly arrested. Do not forget that it may bleed internally when you think it is checked. Avoid warmth, and do not remove your plugs, or pads, which have arrested the hemorrhage, too soon. I have allowed plugs to remain both in the nose and in the throat at the same time for nearly three days without creating much annoyance. These were cases of severe nose-bleedings.

ASPHYXIA FROM EXPOSURE TO COLD.

On its little cheek,
The tear that nature bade it weep, had turned
An ice-drop, sparkling in the morning beam,
And to the turf its helpless hands were frozen.

Asphyxia from exposure to severe cold is not so very frequent an occurrence as we might be led to suppose. It is most likely to occur among the poor, as being ill clothed and worse fed, and in that condition exposed to the rigours of the winter months, which pay no respect to poverty. Persons in the habit of indulging in spirituous liquors are very susceptible to the effects of cold, from the increased perspiration and rapid evaporation from the surface of the body. Generally the fingers, toes, and ears are the first to suffer; next the hands and feet; in fact, the farthest parts from the centre of circulation suffer first, and the enemy continues advancing until he seizes the very citadel (the heart), when death is certain, if means of restoration are not resorted to. A peculiar numbness, insensibility, and strong inclination to sleep, are the characteristics of cold, when severe, on the human body.

The cause of asphyxia from cold is, of course, the abstraction of animal heat.

Things to be done.—As the body has been deprived of its animal heat gradually, every attempt to restore it should be as gradual as the deprivation. For this purpose it is desirable to avoid the application of direct warmth. The first step is to rub the body with snow water, or snow, and it is immaterial where the friction commences, as it should be as general as possible. Where friction is not going on, the parts should be covered with flannels. After some time the water used for friction should be slightly warmed, so as to be *barely tepid*. The room should have no fire at first, but, after a time, the body may be carried into one where there is a fire, or a fire may be put into the room without moving the body.

As the respiration and circulation are not distinguishable, inflation of the lungs with the bellows is necessary; the throat and nostrils should be irritated, or tickled with a feather, &c.

Clysters, with tepid water, in which is put a tea-spoonful of spirits of ammonia, repeated at short intervals. When capable of swallowing, warm broths may be given in small quantities, often repeated. When respiration and circulation are well restored, the person should be placed in a well-aired bed, with plenty of clothing. Drinks should be simple, weak, and warm, but not strong, hot, nor of a spirituous character. If the effects of cold have arisen from previous want of food, the yolk of eggs beaten up with milk and sugar, and a teaspoonful of sherry, may be added. If intoxication has preceded, when the pulse and breathing is well established, emetics or purgative clysters are desirable, as it is probable the stomach, &c. may be loaded with liquor previously drank, which, if remaining, might give rise to considerable mischief. The effects of sudden warmth to persons affected by severe cold, may be followed by violent inflammation, mortification, and death.

Things not to be done.—Never apply warmth at first, nor afterwards, except gradually. Never bleed, on any consideration, in the first stages. It may be necessary when reaction is set up in some cases in full habit of body, but seldom under other circumstances.

ASPHYXIA FROM HUNGER, &c.

"When hunger calls, obey, nor often wait
Till hunger sharpen to corrosive pain."

The cause of asphyxia from hunger is supposed to arise from a specific sensation produced upon the nervous tissue of the stomach, and other organs connected with digestion, by the absence of aliment, producing also changes in the secretions of the stomach.

General Remarks.—There are three circumstances to be considered in this species of asphyxia. It may arise from necessitous deprivation of food; from disease affecting the organs of deglutition and mastication, rendering them incapable of performing the effort required; or it may arise from intention, the patient obstinately refusing food, as in many cases of insanity. I may also add that it may arise from practising too severely total abstinence, with a view of being notorious and deceiving the world. The time which some will bear without food, or with a very small quantity, has frequently been illustrated in general and medical records. The notorious Hannah Moore, and, very lately, the case of Bernard Cavanagh, excited surprise and pity, until the imposition was satisfactorily exposed. There are many cases of shorter duration without food well authenticated, and sufficiently satisfactory

[1] I once had a case of cut throat, where a young and delicate female kept the wound closed by her own efforts a full hour before assistance arrived. So much for presence of mind, which saved in this case a valuable life!

to prove that by practice the human system will bear extraordinary deprivation, and live on a very small quantity of food. In the *Journal of Foreign Medicine* is the history of a person who existed eighteen days without food, and then died. Luc de Antoine Vitubi, a Corsican, existed twenty days. Elizabeth Woodcock, recovered after a deprivation of eight days under the snow; and in *Hufeland's Journal* there is a case related of forty-two days' abstinence. I have often seen four, five, and once seven days passing in which no food was taken. Under the influence of disease (and insanity particularly) a few days of deprivation is not infrequent. Children bear starvation much worse than adults. Lean and aged persons furnish the best examples in such cases.

Things to be done.—Our course must be regulated, in a great measure, by the history of the case. If it be a case of wilful intention, and obstinate refusal of food, it will be found difficult of management, for, though kept alive by compulsion for a time, yet the patient will often ultimately sink. I once had an instance of a woman kept alive four weeks by nourishing injections, but the system gradually sunk, whilst the dogged determination of the patient seemed to increase to the last moment of existence. In such cases the only means are, if practicable, to inject broths, and other nourishing liquids, into the stomach through an elastic tube; but if this cannot be done, nourishing clysters per anum are the only means that are left.

If the case be one of exhaustion, not wilful starvation, the same means are to be used, but the patients are more manageable; the greatest care, however, is necessary only to pour in food in the smallest quantity at a time, and at frequent intervals. It is also equally desirable that the food should be poor at first, and more nourishing as the case improves. By the sudden influx of strong food the most serious consequences ensue—in fact, it is merely a change in the mode of death.

If the case be caused by accident or disease, rendering the powers of deglutition nugatory, the same means are required for the immediate restoration and continuation of life, whilst the medical man must endeavour to remove the disease or obstruction producing it. It is very remarkable how quickly the body runs into a state of putrefaction after real death from asphyxiated cases of this description.

ASPHYXIA FROM THE EFFECTS OF ATMOSPHERIC ELECTRICITY, OR LIGHTNING.

> "Ye sulphurous and thought-executing fires,
> Vaunt couriers to oak-cleaving thunderbolts,
> Singe my white head!"

The frequent occurrence of persons being affected by lightning, renders it necessary to make some observations upon it, although such cases, when really asphyxiated, are looked upon as beyond hope. Dr. Currie, however, mentions two cases, one severely injured, but not really asphyxiated, the other completely asphyxiated by lightning, both of which perfectly recovered. And in the "Collectanea Societatis Medicæ Hauniensis," tom. ii., M. Abilgard affirms, by numerous experiments, that fowls struck down by an electric shock (so strong that they died, if nothing further was done), were completely recovered by slight shocks in other parts of the body, but not by shocks through the head, which first caused the asphyxiated state. If this is a correct view, it is remarkable. It is, indeed, borne out by the fact of electricity and galvanism being known as valuable agents in resuscitation in almost all cases of asphyxia, when they can be procured in time for application. Thus, the power that kills will restore, if used in less degree; that is, if the first power has not by its force produced lesion in some important organ, immediately necessary to life, provided, too, that its application is at a distance from the brain.

Cause of the Asphyxiated State from Lightning.—The suddenness and the extreme power of the electric shock produces immediate exhaustion of nervous sensibility, and most probably lesion of some important organ necessary to life, though it must be acknowledged that, as yet, dissection does not unravel the mystery.

Treatment necessary.—If there is lesion of some important organ necessary to life, it is vain to hope for recovery, but of this we have no means of judging, except on dissecting afterwards; therefore, we must act as if some hope existed, and not give up the case without a trial of means. The best of all means is the cause itself, viz., electricity, used in less degree of force in different parts of the body; perhaps, however, the head should be avoided. Friction, stimulants, inflation of the lungs, must not be forgotten. Bleeding has been spoken of, but I confess, though I have attempted to bleed in two instances, I could not obtain any blood. Almost all the common means employed in asphyxia generally are legitimate means in this case. Sir B. Brodie thinks "death arises from destruction or lesion of cerebral functions." It is a common opinion that the blood is immediately coagulated in these cases. This is an error, and has only arisen from the difficulty of procuring blood. This latter condition is always present where the circulation is suspended, though the blood be not coagulated. After all, there is yet much mystery to be cleared up. Death in these cases is often so instantaneous as to paralyse the efforts of by-standers, and perhaps many sink for want of a little exertion timely given. Instances of recovery are very rare; still, there is hope for which we must contend, and it is possible the prize of human existence prolonged may be gained.

PATHOLOGY OF EXPECTORATION.

By S. Wright, M.D., Edin., F.S.A.

Physician to the Birmingham General Dispensary, formerly Senior President of the Royal Medical and Royal Physical Societies of Edinburgh, &c. &c.

(Continued from page 326.)

To sum up these things, the expectoration of tuberculous sputum is always an evidence of constitutional depravity, which may be hereditary or acquired, permanent or temporary. The former is the most common, but the latter is by no means unusual. I have no doubt whatever that people, naturally healthy, often, from casual disturbance in the functions of their blood, have tubercular matter formed in this fluid, just as under other circumstances pus may be formed in it. The generation of this matter simply indicates a depravation of the elementary process of nutrition, and if the morbid action persist only for a time, and the issue of it (tubercle) be discharged by some emunctory organ, the system finally suffers in no serious degree in consequence.[1] When, on the contrary, this perversion of elementary nutritive function is continuous, the whole fabric wastes, and the patient dies of marasmus; and when the matter, instead of being eliminated, is deposited in some organ, its subsequent decomposition sacrifices that organ more or less, and in that ratio, and the ratio in which such organ is destined to subserve the whole animal economy, will the results of this local deposition and decay be fatal. But it will be understood from the preceding observations, that the evidence of constitutional disorder which tuberculous sputum furnishes, is not necessarily the forerunner of a fatal issue, and that this latter is most likely to be the case when the patient wastes with the spitting, or when some important organ is suffering, as the stethoscope or other means of physical examination will indicate, from obstruction or decay.

Local Symptoms and Physical Signs.—Tubercular sputum, as we have said, is sometimes met with when the lungs are free from disease. In these cases percussion of the chest elicits no abnormal sounds, and auscultation seldom detects anything unusual in the respiratory murmur beyond a little crackling, whistling, or bubbling ronchus, due, perhaps, to bronchial dilatation or flattening and the presence of an increased quantity or viscidity of the natural mucus of the parts. The cough is generally troublesome, and "thick mucous," or "muco albuminous sputum," is discharged, often profusely, in the intervals of the expectoration of the tubercular matter. A thinner sputum, it may be sweet or saline, is sometimes observed. The patient usually complains of dryness in his throat, and his voice is occasionally husky, but without its organs being ulcerated. Again, the larynx and trachea may be the only suffering parts, and the stethoscope distinguishes a dry, grating, whirring, or wheezing noise, especially during expiration, and the voice is unusually shrill, or whistling, or sonorous, or irregular-toned, squeaking, and tremulous. Deglutition is often painful, but respiration, and particularly talking, is distressing in the extreme. When the lungs themselves are the seat of tubercular deposition, the physical signs will vary with the amount of tubercle present, and with its particular state. When the tubercles, in their miliary form, are scattered throughout the substance of the lungs, and not very numerously in any single spot, it is rare that percussion can detect anything unnatural in the sound of the chest. I possess a portion of the lower half of the lung of a patient I attended about nine months ago, for consumption; this portion, like the rest of each lung, is thinly scattered throughout with miliary tubercles; no tubercle was found in a matured state, nor was there any cavity. The stroke sound of the chest in this case was unimpaired, and auscultation only recognised, here and there, up and down the chest, a sub-mucous and sub-crepitant râle, due to the partial bronchitis established by the contiguous irritant action of the tubercular bodies. The patient occasionally spat a little tubercular matter, derived, no doubt, from the mucous surface of the trachea or bronchi, but his chief expectoration was, at first, "thin mucous sputum," such as is often consequent upon the early state of tubercalisation of the lungs, and finally, and continuously, "thick viscid sputum," alternately transparent and opaque, just such as indicates inflammatory action in the bronchial ramifications. These signs, added to hectic and wasting, were all upon which a diagnosis of consumption could be founded. Such cases are not of infrequent occurrence, and generally prove a source of perplexity to the inexperienced practitioner. Indeed, whatever may be a man's experience and skill in the physical diagnosis of chest disease, he has often much difficulty in pronouncing upon cases like the preceding, and especially if the tubercles continue in their miliary state. Sometimes there will be neither cough nor expectoration, and the patient sinks under a slow marasmus, without any organ in particular appearing to be implicated in the mischief. Usually, however, auscultation and the sputa serve our purpose pretty faithfully, with the assistance of other symptoms, in deciding upon our patient's disease and probable destiny. Acute bronchitis is seldom of long continuance, and the respiratory sounds which accompany it either become aggravated into the distinct crepitating râle of pneumonia, with its viscid rusty sputum, or subside into the bubbling mucous, and sonorous or sibilant ronchus, with the copious, heavy, opaque, pellety, mucous expectoration, indicative of chronic bronchitis. But

[1] Local injuries, again, occurring to people not of scrofulous diathesis, but of bad habit of body at the time of the accident, are often followed by unhealthy inflammation, and the formation of tubercular matter as well as pus. I have repeatedly, under these circumstances, recognised tubercle in the fluid of suppuration, and yet the patients have subsequently recovered, and the temporary tubercular genesis has left no trace, beyond a scar, of its action and issue. And in people naturally scrofulous, we know that inflammation, especially of their joints, is frequently attended by the local deposition of tubercular matter—in white swelling, for instance. In many of these cases, the matter having found an exit, and an open suppurating surface having been established, tubercular substance will continue to be secreted and discharged as abundantly as pus; and yet such subjects often recover from amputation, and are never again visited with a repetition of their local malady. And, on the other hand, inflammation of joints and of absorbent glands is commonly enough followed by the deposition of tubercular matter that is finally absorbed in whole or in part, or is kept securely encased in its nidus, and is discovered after death, lying harmlessly like a mass of putty or gypsum. And this would as often happen in cases of tubercular deposition in the lungs, but that, as tubercle after its maturation becomes dead matter, and liable to the play of chemical affinities between its constituents, this liability is constantly heightened by the incessant accessions of fresh air which act upon it in the process of respiration. But occluded tubercle escapes this continued stimulus to decay.

when the irritant and sub-inflammatory action of the bronchi, as shown in the constant hacking cough, the muco-crepitant or sub-crepitant râle, and the profuse expectoration of glairy viscid sputum, or thin semi-transparent sputum, salt or sweet, continues, the patient at the same time wasting, we may be almost certain of the presence of tubercles in the lungs, though they may be so scattered as not to afford any immediate and positive signs of their presence.[2] But it most commonly happens that tubercular deposits in the lungs have a tendency to aggregate in places. The most frequent locality of them is under one or both clavicles, but especially the left. When tubercles exist in such situations, percussion over them elicits a dead or dull sound, which exactly defines the extent of the morbid deposit. In proportion to its amount, also, will the corresponding ribs be imperfectly moved in the act of respiration.[3] The auscultatory sounds will of course vary with the degree to which the tubercular substance obstructs the vesicular tissue of the lungs, and modifies their natural movement and tone. There are many stethoscopic niceties which only few people are fortunate enough to attain to in practice, and I must confess myself to be one of those who are competent to decide only upon signs and sounds which are not of very doubtful character and import, and am content to leave the delicate distinctions, so often prettily represented in books, to be carried out in bed-side practice by such as have senses acute enough for the task. In confining our attention to such things as are plain, unpretending, and easily available, rather than to such as are ornamental and curious, we shall find that there are a few stethoscopic signs which represent with tolerable accuracy the state and function of the lungs in the different phases of consumption. It must be understood that the abnormal sounds which accompany the successive definite stages of phthisis, are directly representative of the amount of foreign matter deposited in the lungs, or of the extent to which these organs are ulcerated and destroyed.

As the deposition of tubercle advances in the lungs, the natural respiratory murmur diminishes in the sub-clavicular, claviculo-axillary, and supra-scapular regions, and finally becomes either totally suppressed throughout, or in particular spots, whose silence contrasts with an unusually loud murmur in other, contiguous, places. In the vicinity, and throughout the substance of the consolidation, the expiratory sound of respiration is heard with unnatural distinctness, and partakes of a grating, blowing, ringing, or whiffing character. These sounds may be of regular duration and intensity, or, as sometimes happens, irregular and jerking. They arise either from partial depositions of tubercle, which occasion a corresponding degree of obstruction to the ingress and egress of air, or from complete tubercular consolidation of the vesicular tissue of the lungs, which renders respiration in such parts exclusively bronchial; and according as the bronchi are elongated or widened, or flattened and narrowed in places, will they emit a corresponding variety of sound. The sound of the voice, too, is generally audible in a marked degree, either of expression or resonance, over the seats of tubercular deposition. In parts of the lungs contiguous to the spots of tuberculisation, the proper murmur of respiration is usually found to have given place to a peculiar râle, occasionally mucous and sub-crepitant, but mostly dry and crackling. The phenomenon has never been explained, that I am aware of, and Dr. Walshe states that the cause of it is yet unascertained.[4] It appears to me, however, that this ronchus, which seems to be nothing more than a *friction sound*, is produced by the irregularity of situation and shape into which the permeable air-cells of the lungs are thrown by the pressure and tension of tubercular matter and false membranes and bands in different parts of the pulmonary structure. This râle is chiefly heard at the commencement of phthisis, when the air-cells of the lungs contain no more fluid than usual. The passage of air into and out of these irregular-shaped cells, would of course give rise to a variety of sound, which, aided also by the want of uniformity of action in the cells themselves during the respiratory process, would be sufficient cause of the singular crackling ronchus spoken of. In some cases of commencing phthisis it is not observed, for, owing to the presence of a more than natural quantity of mucus in the air-cells of the lungs, or in the minute bronchi, only a mucous or muco-crepitant râle is heard. For the like reason, the crackling ronchus is seldom heard after the first stage of phthisis.

It often happens that tubercles will be formed, and extensively, too, in the lungs, without exciting any evident irritation, or occasioning any cough. I have seen several cases in which the first stage of phthisis has been passed over with scarcely any cough, and with no expectoration whatever. Usually, however, the presence of miliary tubercles in the lungs gives rise to a little sympathetic irritation in the leading aerial passages—in the larynx, trachea, and bronchi—and the consequence is, an almost incessant "tickling," as the patient calls it, in his throat, a frequent hacking cough, and an expectoration of thin mucous sputum. The quantity of this is sometimes very considerable, amounting to two or three pints in the twenty-four hours. It is chiefly in young subjects, especially females, that its profusion is marked, and it is a pretty sure diagnostic sign either of extreme nervous susceptibility, or of extensive and scattered tuberculisation of the lungs. In subjects of more advanced life, and in such as have suffered from frequent bronchitis or pneumonia, the first stage of phthisis is generally attended by an expectoration of thick mucous sputum, of variable density and opacity, and often containing traces of pus. In others, again, the expectoration will be chiefly purulent from the beginning, and in some cases even crude tubercle will be spit up; the deposit in the lungs retaining, as we have said, its miliary character.

The signs which physical diagnosis furnishes of the maturation of tubercle, *i. e.*, of its change from a miliary to a crude or cheesy state, are seldom worthy of any confidence. We are told, by a distinguished authority (Dr. Williams), that "it can hardly take place without some augmentation of the consolidation—hence there is a fuller development of the signs of an increased density of the lung; the partial dulness on percussion becomes more marked," &c.[5] These more marked indications of tubercular deposit may occur, if, during the maturation of the old tubercle, fresh crops of tubercle should be formed, as is sometimes, though I do not think very frequently, the case. But it has quite as often occurred to my observation to discover no change whatever in the previous sounds of the chest, and I have noticed a diminution of dulness, both in intensity and extent, and an unexpected post-mortem has revealed that, with this seeming improvement, the maturation of the tubercles has been rapidly advancing.

The indications which are furnished by the sputa, and by the more general morbid symptoms, are safer guides in diagnosis, but they are not constant, nor are they always correct; yet I believe them to be more trustworthy than any others, and therefore do not hesitate to urge their adoption. The process of tubercular maturation in the lungs almost invariably occasions an increase of irritation in these organs, and in the bronchi and trachea. The common consequences are, a greater difficulty in breathing and a more frequent cough. Percussion over the affected part causes pain or smarting, and the patient coughs incessantly whilst you are tapping his chest. He is more irritable than previously; his nights are restless, and his sleep disturbed; and, when recumbent, he is constantly changing his position. He generally prefers to lie partially on his face, rather than on his sides or back. His pulse is quickened, and hectic either appears for the first time, or, if it were before a symptom, it becomes aggravated. In every case I have investigated, the quantity of expectoration, whether great or small in the primary stage of phthisis, became, to a certain extent, reversed as the tubercles began to maturate. If the sputum were thin and profuse at first, it subsequently became less copious and of greater consistence and opacity; and conversely, the thick mucous kind was exchanged for the thinner and more transparent variety, either abundant or scanty. Either of these forms of sputum, also, was succeeded by muco-purulent, or purulent expectoration. I believe it rarely happens that the sputum which accompanies this, the commencement of the second stage of phthisis, is free from some distinguishing peculiarity in appearance or taste. These several marks of distinction may be met with in the sputa of other diseases than consumption, and occasionally in all stages of this malady, and are therefore not unexceptionable evidence in diagnosis, but, aided by other signs and symptoms, I have seldom found them faulty. The most common appearance is frothiness, constant or occasional, and of all shades and degrees. (See frothy sputum.) With this the sputum may be transparent, opake, pearly-white, or variously coloured. Its peculiarities of taste consist in its being sharp or acrid, saline, sweet, sour, or bitter. Of these, the saline and sweet are the most common.[6] The latter is often remarkable when the sputum is muco-purulent, but it as frequently depends upon a depraved condition of the mucus itself. The saline taste is chiefly met with in the thin variety, and it usually indicates an excessive degree of local irritation, or of general nervous excitement. The others are perhaps owing to some modification which the secernent function derives from a state of cachexy or digestive derangement.

[2] In these cases also, contrary to what we observe in ordinary bronchitis, the râles are chiefly confined to the sub-clavicular, axillary, and supra-scapular regions.

[3] If the quantity of deposit be considerable, the hand applied over its site recognises an unusual vibration when the patient speaks or coughs. This is a diagnostic sign which is liable to some exceptions, and requires a little delicacy of manipulation to render it available and trustworthy.

[6] They chiefly prevail in the morning expectoration, but not unfrequently they occur at intervals during the day.

CASES OF HYDROCEPHALUS, WITH REMARKS.

By HENRY KENNEDY, A.B.

(Read before the Obstetrical Society of Dublin.)

In the present communication I purpose bringing under notice the details of a few cases of hydrocephalus, which have come under my observation from time to time, and which may not be considered void of interest.

Case 1.—A girl, ætat. three years, was attacked with dysentery; the attack was accompanied with all the usual symptoms, and in a very aggravated form. It yielded, however, at last, about the tenth day, and the child seemed to have been convalescent, when, about three weeks after the first appearance of the dysentery, it was suddenly seized with convulsions of one side of the body. Leeching the head and purgatives had at once the effect of lessening the convulsions, and the following day no trace of them was visible. The child, however, now laboured under high fever, the head being remarkably hot; it is enough to add, that from this time hydrocephalus showed itself in a well-marked form, and the child sunk on the eleventh day, reckoning from the first appearance of convulsion. I was not able to get any examination. Had this been a solitary example, I should scarcely have deemed it worthy of notice; but it is not so. I have both seen and heard of several cases precisely similar; that is, where an attack of dysentery seemed to lay the foundation for one of hydrocephalus. It is well known that Cheyne, in his very valuable work, has put strongly forward the idea that derangement of the bowels very generally precedes an attack of water on the brain; and though he has not mentioned dysentery as a precursor of the disease, still the case given, and those similar to it, are strongly corroborative of the truth of his opinion. In one of the cases alluded to, where an examination was made, the quantity of effusion into the brain was very considerable; one ventricle was dilated more than the other, but the membranes were not engorged at all. There were several distinct specks of ulceration in the colon, while the mesenteric glands were much enlarged and injected. The commencement of the head symptoms, as in the case detailed,

by convulsions, is by no means uncommon; as far as I have seen, it is a symptom of very unfavourable omen to usher in the attack. I believe, in fact, the reason of this is, that the symptom is merely symptomatic of mischief that has been gathering for some time previously, but which has not been observed by the mother or friends; and considering hydrocephalus, in nine cases out of ten, to be not only a local, but a constitutional affection, that it is to be regarded but as one link in a long chain of morbid effects.

Case 2.—I was asked by my friend, Surgeon Hamilton Labatt, to visit a child about six years old, labouring under well-marked symptoms of water on the brain. Everything that could be done had been done, and in the most judicious way; among the rest, the system had been brought under the influence of mercury. The child lived about twelve days after my seeing it, going through all the regular stages of the disease; it was at times comatose, but again would almost entirely recover its senses, and even after having had severe fits of convulsions the same thing took place.

I have mentioned this case, because it afforded a very good example of the presence of a symptom which is not unusually met with in hydrocephalus, but which is very necessary to be aware of; indeed, the medical man may readily be thrown off his guard by it. I allude to the return of consciousness after coma or convulsions had previously existed. It has on several occasions come under my notice. I recollect a case which I saw with my friend, Surgeon William Barrett, where it existed to a very remarkable degree. In a case, too, which occurred very lately in Sir P. Dun's Hospital, under the care of Dr. Baker, it also existed, but not in so marked a manner. Cheyne details several cases where it took place. It is also well known that it is met in other diseases besides hydrocephalus. It must be allowed that the fact, *per se*, is a very curious one, but one which, I fear, it would be very puzzling to give any rational explanation of. It can scarcely be supposed that any organic changes could take place in so short a time, which might account for it, but which changes must again, in an equally short time, disappear; and yet, on the other hand, it would be very unphilosophical to suppose that these symptoms could exist without a cause. The point, however, may be learned from the fact stated, namely, that in head cases we should be very cautious in connecting the symptoms during life with the post-mortem appearances.

Case 3.—In the course of last year, I was taken to see a boy of 14 years of age, labouring under illness. During the two previous years he had been twice affected with fits, which, from the account I got of them, seemed to have been of the epileptic character. I found him in bed, his countenance heavy, and expressive of pain, which he referred to the head, but not to any particular part of it. He had not been observed to be drooping before this. His pulse was only 60, and it struck me as being very feeble; there was scarcely any increased heat of skin, or of the head, but the tongue was densely loaded, and indeed out of all proportion with any other symptom; the eye was perfectly clear. Under the inpression that the stomach was at fault, he was ordered an emetic, and this was to be followed in three hours after by a brisk purgative. I saw him again soon after this, and found, somewhat to my surprise, that the emetic had no effect, but that the purgative which had been given had acted smartly on the bowels. Still the head was not relieved. It is enough to mention, that he remained in precisely the state detailed, without any variation whatever, for four days; during this period the head was leeched, and he was getting continuous doses of colomel with James's powder. He was then removed to the hospital. I am unable to give any detail of his symptoms while there, except that previous to his death he was affected with coma and violent convulsions. The case ran a course of about seventeen days. There was a good deal of general subarachnoid effusion; the membrane being also opaque and thickened in patches; at the base and particularly at one side, extending into the fissure of Sylvius, there existed a deposit very like minute tubercles; it had clearly been of some standing. The amount of effusion into the ventricles was very moderate.

I have given this case on account of the peculiarities which it presented. It has never happened to me to meet with any case in which the symptoms were similar at the same period of the disease. It will be recollected that at the very onset of the attack the pulse was but 60, and that it remained so for at least four days. In every other case of the kind I have seen, the first stage has been ever one of marked excitement. Here, with the exception of the tongue, there was no appearance whatever of fever: possibly the patient having originally had fits, they may have modified the symptoms of his last illness. It is of course well known, that in many cases of chronic disease of the brain, one of the most characteristic symptoms is a slow pulse, such as was present here. It is a curious point connected with the case, that the emetic which was given had no effect; vomiting attends by far the greater number of these cases, and yet here, where it was solicited, it did not occur.

Case 4.—In the year 1839, I was asked to see a child, ætat. 1 year and 10 months, who had been ill four days, and whose illness had begun during the night with fits of screaming. Previous to my seeing it leeches had been applied to the head, and it had got some medicine, I believe calomel. There had been no vomiting. The child had very high fever; it was constantly tossing about its head, and took at times fits of violent screaming. It lay in a state of stupor almost amounting to coma, but it had evidently some sensibility, for it winced on pressing the abdomen, which was somewhat tympanitic. It was able, too, to swallow drink. The discharges from the bowels were nearly black. The pupils were very sluggish on exposure to light. The treatment consisted in active purgatives, leeching the head, and blistering it; a stimulating liniment was also rubbed on the abdomen, and the gums were freely lanced. It is enough to add, that on the third day after my seeing it the symptoms began to improve, the fever came down, the nights became quiet, and the stupor, in which the child had lain for days, left it, but very gradually.

This case has not been brought forward as one of hydrocephalus; at the time I saw it, however, I was much puzzled to decide on its nature, and to this day am unable to say whether the cause of the symptoms lay in the abdomen or head, or both combined. I have seen other cases, where children were affected with different degrees of drowsiness and stupor, but none to such a degree as this case; that is, where the child recovered. Dr. Dwyer may probably recollect an interesting case of this sort, where the child would apparently fall asleep, or, rather, get into a state of stupor, the moment it was left quiet. This child had other symptoms, too, threatening water on the brain, but is now quite well.

Case 5.—About five weeks since, I was [illegible] to see a boy labouring under high fever. He was nine years old, and a brother and sister had died within the two last years of water on the brain. He had been complaining for two or three days previous to my seeing him, and had been observed looking ill; and his mother had given him two doses of medicine, which had acted briskly on the bowels. I found him, as I have stated, labouring under high fever: the skin was burning hot; the tongue furred; the pulse upwards of 130; the eyes much suffused; and he had had vomiting. He complained bitterly of his head, could not bear either the light or any noise, and even any attempt to move him made him cry out with pain. It is enough as to the treatment to state, that he was leeched on the temples, and behind the ears, as often as prudence would justify; besides this, mercury was used; and, by the third day, I had the pleasure of finding that all pain had subsided, that the fever was coming down, and the system gradually, but steadily, coming under the influence of the mercury. By the sixth day, there was scarcely anything to contend with but weakness, which went on, however, to a greater degree than could have been wished; for four or five days it was, in fact, almost enough to alarm one. It was more complained of by the boy himself, than evidenced by any particular symptoms; for I observed that, when he wished, he was able to turn himself, and the pulse had all through retained a fair degree of strength. During this latter period of his illness, he was a good deal troubled by a short, hard cough, which arose from bronchitis. With care, however, and by removal to the country, he has gradually come round, and may now be pronounced quite well. While this boy was labouring under the state of weakness alluded to above, I had the valuable assistance of Sir Philip Crampton.

I have given the particulars of this case, because it forcibly illustrates the value of a plan of treatment which is, probably, not in so general use as it deserves to be in cases of this sort, but which has not yet been alluded to this night: I mean the use of an issue. This boy had had one in the arm for a considerable period previous to the attack which has been described, and I do believe it was owing to its effects on the system that the treatment adopted here was successful; at least, I know that the chances of stopping a disease like hydrocephalus in one of a family where there is a predisposition to it, is, in my experience, very slight, no matter how early the case may be seen. That water on the brain was threatened, in the case which has been detailed, there is, I think, no reasonable doubt: the previous existence of the disease in the family showed the predisposition, and then every symptom was present which is commonly met with at the onset of the attack, and this, it will be remembered, after the bowels had been well acted on by medicine. As to the extraordinary weakness which followed the attack, it may be fairly, in part at least, attributed to the treatment, coupled with the fact of the boy being naturally of a delicate constitution.

Such are some of the varying forms under which hydrocephalus, like every other malady, presents itself. Of the nature of this disease, I have expressed my opinion before. I agree fully with those who believe it to be a constitutional affection, in the great majority of instances; and that the head symptoms are merely a portion of the evidence of the fact that the entire frame is diseased, and partakes strongly of the strumous diathesis. This view, and this only, will account for the great fatality of the disease, when once head symptoms have declared themselves. It also accounts satisfactorily for the difficulty which often exists in distinguishing between infantile remittent fever and hydrocephalus—a difficulty which, I believe, in many instances, cannot be cleared up, inasmuch as the former frequently ushers in the latter disease.

On the treatment of this disease, I have nothing to add to what is already known. Its pathology shows that it will not bear, as a general rule, an active antiphlogistic treatment, such as some have advocated. In the next fair case that offers, I shall certainly make trial of the long issue, which was recommended some time back in one of the London periodicals; the name of the gentleman who spoke of this plan has, however, escaped my memory.

TARTAR EMETIC IN PNEUMONIA.

By F. W. CHRISTIE, Esq., Surgeon, Knotty.

Case 1.—Richard Whattle, ætat. 45, of very intemperate habits, and much exposed to the vicissitudes of the atmosphere, was attacked with cough and *slight* pain in the left side early in March, and soon fell into general ill-health, but still pursued his usual habits; at length, when he could hold out no longer, he applied to me, and, after a careful examination, I found him in the following state:—The countenance and prolabia livid, and indicative of suffering; the temperature of the body, especially of the extremities, much diminished; pulse weak and rapid; considerable dyspnœa, increased on slight exertion; incessant cough, with expectoration of viscid, tenacious, *ropy*, rust-coloured sputum. On percussion, the whole side of the thorax sounded perfectly dull. The stethoscope pointed out a total absence of the vesicular or respiratory murmur; at the sub-clavicular region there was slight, but circumscribed, crepitating râle, with some little clearness of sound on percussion; bronchial respiration was generally distinct; he could only lie on his *back*.

Diagnosis.—Pneumonia in its second stage, or that of red hepatization, occupying the three in-

ferior fourths of the left lung, and in its first stage, the upper portion.

Prognosis.—Most unfavourable, from the stage and extent of the disease, the age, and broken-down condition of the patient, who was at the time also in a state bordering on delirium tremens.

Treatment.—R. Tart. ant. et potas. gr. vi, Aqua ℥ vi, Nitr. potas. ʒj. M. st. coch. ij om. hora. The first and second doses produced severe vomiting and purging, but to his great relief, as his chest seemed emptied of an enormous quantity of the ropy mucus characteristic of pneumonia; he persevered in its use, and tolerance of the remedy was soon established, and under its use alone he daily improved; his pain and cough subsided; his countenance became expanded; the dull sound of his chest, and then the crepitating râle, vanished, and in six weeks the healthy respiratory murmur was gradually re-established over the greater portion of his lung. I should have observed, that I daily increased the quantity of tartar emetic, until he took twelve grains daily, without any inconvenience; in fact, his appetite improved under its use, and he had no relapse during his convalescence, which I may date from the first dose of this medicine, the effects of which were really astonishing. The almost immediate amelioration of all the symptoms of his malady, both physical and stethoscopic, caused me to look on this medium as "an heroic remedy" indeed, and the following case shortly after coming under my care, I confidently looked for a favourable issue, and was not disappointed.

Case 2.—E. B., ætat. 24, a young woman of lymphatic temperament, had for several months been in indifferent health, but not altogether prevented from following her occupation, that of a servant. She suffered from dyspnœa, palpitation, slight cough, and *uneasiness* in the right side; at length she had a slight attack of pleuritis, for which she applied to a medical man, who bled and blistered her; relieved her urgent symptoms, and told her *she was well.* She applied to me, and exhibited the following symptoms:—As in the former case, the temperature of the body was much diminished, as if the power of developing animal heat was withdrawn, owing to the non-oxygenation of the blood; the countenance was *puffed*, and of an unhealthy *blue;* there was great dyspnœa, palpitation, and indisposition to exertion; cough and expectoration very little, but that little very characteristic.

Percussion yielded a dull sound generally, and there was œgophony at the root of the lungs, showing some effusion from the pleuritis. The measurements of the thorax were normal, and she could only lie on her back, and occasionally on the affected side.

I ordered a grain of the tartar emetic every third hour, in an ounce of infusion of orange-peel, and directed a croton oil liniment to be rubbed over the affected side. She was purged and vomited by the first few doses, but I soon was enabled to increase the quantity of her medicine to ten grains daily, under which her convalescence steadily progressed, and her lung has almost resumed its healthy function. Her stomach, which had been very irritable before her illness, became perfectly quiet, and her appetite also was improved, even while using so large a quantity of what is usually termed an irritant poison.

I will abstain from all theorising as to the modus operandi of the tartar emetic, but at the same time cannot attribute it to its counter-irritant effects on the intestinal mucous surface, as it became perfectly quiet after the first few days; nay, she even required purgatives occasionally. Even Rasori himself, and after him Laennec, have failed satisfactorily to account for its acknowledged extraordinary effects, and these cases show that slow, insidious, chronic pneumonia is much more frequent than Dr. Marshall Hall imagines.

CASES OF POISONING BY ÆTHUSA CYNAPIUM, OR FOOL'S PARSLEY.

By EVAN THOMAS, late House Surgeon to King's College Hospital, Fellow of the Royal Medico-Chirurgical Society, London.

Ellen Williams, ætat. 5, was in excellent health till Tuesday morning, May 27, 1845, when, after eating the bulbs of the æthusa, which were mistaken for young turnips, she was attacked suddenly with pain in the pit of the stomach and belly, followed by sickness, but no vomiting; complained of being very ill; tried to eat, but could not swallow; she was now incapable of answering questions, the countenance wearing a wild expression; the lower jaw became fixed to the upper, so as to prevent any thing being introduced into the mouth; and towards the last she became insensible, and died in an hour from the commencement of the symptoms, without either hiccup or convulsions, as far as could be ascertained from the account given by the friends.

Anne Williams, ætat. 3, was in excellent health till the same Tuesday morning, when, shortly after eating the same substance, she was attacked with pain in the epigastrium, sickness, vomiting, and profuse perspiration; soon afterwards she recovered, with the exception of excessive griping pains in the belly, without purging, which ceased on the following day.

John Roberts, ætat. 3, was in excellent health till Tuesday, May 27, when, after eating the so-called turnips, he was attacked with pain in the throat, pit of the stomach, and belly; this was followed by sickness and vomiting, and the following day he was well.

Remarks.—The first case had terminated fatally before any assistance could be obtained, being ten miles distant from my brother, who was the nearest medical man; the second and third had recovered without any other than spontaneous vomiting. No post-mortem inspection could be obtained, consequently the morbid appearances, if any existed, must be left a matter for conjecture. At first I had my doubts whether the substance alluded to was the cause of death, till the corroborative evidence, with reference to the other cases, was brought forward at the coroner's inquest. I performed several experiments upon dogs and cats, with the view of obtaining more accurate information as to the virulent properties of the æthusa, having first obtained the opinion of Professor Forbes, of King's College, as to its identity; the preparation employed was the recent juice of the bulb, dug up at the time this happened (May). About two ounces of the expressed juice were injected into the stomach, through a wound in the œsophagus, which was carefully exposed high up in the neck, and afterwards firmly secured with a ligature, passed on the cardiac end of the wound. All the cases but one died in from one to four hours; as far as I am able to judge, the symptoms produced were violent spasms and urgent attempts to vomit. Nothing wrong was found in the stomach or elsewhere, except in one case which lived twelve hours; the mucous membrane of the stomach was marked on its anterior and posterior surfaces with black stains, the result of the gastric secretions. I ought to say that the animal had been kept for a long time without food, previous to the operation.

[The patients who recovered had eaten the æthusa on a full stomach, and vomited immediately afterwards, to which the happy result may probably be attributed.]

PROGRESS OF FRENCH SCIENCE.

(FROM OUR OWN CORRESPONDENT.)

Paris, August 18, 1845.

Aural Surgery.—The number of the *Archives Générales de Médécine* for August contains several interesting papers; the first is one by Dr. Laugier, surgeon to the Hospital Beaujon, on the diagnostic value of the escape of a limpid fluid from the ear, in injuries of the head. In nine cases, published at some length, with their post-mortem examinations, Dr. Laugier constantly found the *petrous process* of the temporal bone *cracked*, and a more or less considerable amount of coagulated blood accumulated over the fracture. The dura mater was not lacerated. From these cases, Dr. Laugier concludes, 1st, that the discharge of a watery fluid from the ear, after injuries of the head, indicates a fracture of the petrous bone, and a communication abnormally established between the cavity of the cranium and that of the tympanum, or the meatus auditorius externus. 2d, That the origin of such liquid is the effusion of blood consequent upon the fracture, and the extravasation of the serum from the divided vessels. 3d, That when, from the coexistence of paralysis, or other symptoms, with this watery discharge, the application of the trephine is resolved upon, the instrument should be applied above the meatus auditorius externus, in preference to any other spot.

M. Beau's important researches on arterial sounds we will notice in our next communication, and also a paper by M. Toussey on the various forms of insanity.

Academy of Medicine; meeting of August 12; M. Caventou in the chair.

Treatment of Mucous Fever; by Dr. Giraud.—A favourable report was read by Dr. Collineau. M. G. recommends, in the treatment of mucous or typhoid fever, the application of heated bricks to the skin, in order to promote diaphoresis, and repeated vesication of the lower extremities.

Dr. Louis observed that the practice of blistering in typhoid fever seems, from the analysis of a large number of facts, to be both useless and dangerous, from the tendency to ulceration and gangrene of all sores in cases of typhoid fever.

Phlebotomy.—A practical paper on this subject was then read by Dr. Tanchou. The author remarks, that in venesection the stream of blood is generally black at first, and becomes by degrees of a brighter colour; that from beginning to end of the operation, the blood is occasionally scarlet; that it is often of both colours at once; and lastly, that the stream may be of a bright hue at the first gush, and become dark towards the close. Now, M. Tanchou is of opinion these various changes are due, in some cases, to the rapid passage of arterial blood into the venous system, and in general to the arterialising action of the air on the venous blood through the texture of the skin; an action illustrated by the brighter colour of the venous blood in the child than in the aged. From the *colour* of the stream, therefore, Dr. T. judges the operation should be continued, suspended, or repeated; and he deems the consideration of the colour to be a much safer guide than the formation of a fibrinous coat on inflamed blood, this crust forming on the blood only when it is too late to prevent the mischief which arises, in some cases, from any kind of depletion. The author grounds his opinions chiefly upon personal experience, and in conclusion asserts that black venous blood may be allowed to flow without apprehension, but that a scarlet stream should, on the contrary, be instantly arrested.

Academy of Sciences; meeting of August 11; M. Elie de Beaumont in the chair.

Purpura Hemorrhagica—Morbus Maculatus Wertofhii.—A paper on this subject was read by Dr. Legrand, wherein two cases were related—one of fatal purpura consequent on pulmonary consumption, the other cured by the administration of lactate of iron and stannate of gold. This substance was exhibited at the dose of 1-10th of a grain twice a-day.

Sudden Death from Electric Agency.—A physician practising at Coulommiers (Dr. Régnier) sent to the Academy an account of a case of sudden death from the action of electricity. A young peasant-girl was struck dead as she was retiring from a field overhung by a heavy cloud. On examination of the body, the hair of the axillæ was found burned; no other lesion could be discovered. At a small distance from the body was her cap, pierced with a small hole. M. Régnier considered that death had been produced by the electric fluid accumulated in the soil, and transmitted to the cloud through the body of the victim, who thus served as a conductor. M. Arago admitted the plausibility of this explanation, and mentioned two similar instances which had come to his knowledge.

Medical Reform in France—Congress.—The delegates of the medical societies of Paris met on the 2nd August, in the amphitheatre of the Academy of Medicine, for the purpose of considering the expediency of calling a general meeting of the profession. The object of the proposed congress will be to discuss the interests of the medical body in France, and to report to the Minister of Public Instruction the opinions and wishes of the majority of its members. A new law on the organisation of medical schools and of medical practice is in preparation, and, it is confidently asserted, will be presented to the Chamber of Deputies in the spring of 1846. If such be the case (and there is every reason to believe it) the imposing manifestation of opinions,

emanating from a congress, would doubtless assist considerably, and simplify the labours of the Committee of the Chamber of Deputies, whilst it must accumulate a considerable amount of practical knowledge on the subject of medical reform, at present scattered amongst individuals. Many of the most important questions connected with the profession, such, for instance, as the institution of the Concours—the mode of examination—the advantage or disadvantage of two distinct degrees in the profession—the legislation on medical responsibility—on secrecy—on the illegal practice of medicine, &c., have not yet, strange to say, received a definitive solution, and we are inclined to think that public and free discussion of all these topics will be of material service to the profession in this country in more than one point of view. At the meeting of the 2nd August upwards of two hundred delegates from the various societies were present. The chair was taken by Dr. Bataille. A report from the Committee of Organisation was read by Dr. A. Latour; it was received with much favour, and unanimously adopted. The first meeting of Congress was adjourned to 1st November, 1845. The Committee there resigned its functions, and the following gentlemen were elected to pursue its labours:—nine physicians, three representatives of the Society of Pharmacy, and three veterinary surgeons—Dr. Villeneuve, President, Member of the Academy of Medicine; M. Boullay, Vice-President; Dr. A. Latour, Secretary; Dr. Malgaigne, Vice-Secretary; Dr. Richelot, Treasurer; Dr. Moreau, Professor of Midwifery at the Faculty of Medicine; Dr. A. Béraud, Professor of Clinical Surgery at the Faculty of Medicine; Dr. Ségalos, M.A.; Dr. Blatin; M. Dubait; M. F. Boudet; M. Leblanc, Veterinary Surgeon; M. Hamon, ditto; M. Collignon, ditto.

Concours.—After a brilliant *concours* Dr. Villeneuve and Dr. Gossalin have been appointed surgeons of the hospitals of Paris.

DAN. M'CARTHY, D.M.P.
President of the Parisian Medical Society, late Interne of the Hospitals of Paris.

PROGRESS OF GERMAN MEDICAL SCIENCE.

BY SIGISMUND SUTRO, M.D.

Peculiar Effect of Indigo.—About ten years ago indigo was used, and strongly recommended in different forms of spasms and convulsions, and especially in epilepsy. The observations then made were very favourable to its use. The author also frequently administered it, but could not confirm the favourable reports by his own experience. He could never effect a complete cure by it; recovery seemed to have ensued in several cases, but the convulsions unexpectedly returned. The author found the nitrate of silver much more useful in epilepsy. He, however, only communicates in this article a peculiar phenomenon which he observed from the use of indigo. A delicate, but healthy female, with a tender skin, suffered for a long time from clonic spasms of the chest, which seemed to indicate the employment of indigo. The spasms, originally caused by a violent cold, had lasted for several years, and seemed to proceed from disturbance of the digestive organs. Two drachms of indigo were ordered, with two ounces of some aromatic powder, and arranged the doses so that she took about half a drachm per diem. But in this dose the remedy caused great uneasiness, nausea, vomiting, and diarrhœa. The dose was reduced to ten grains a-day, when no sickness ensued, but diarrhœa was frequent. In this small dose the remedy was taken for a fortnight, without any peculiar symptoms. On the fifteenth and sixteenth days, however, fever appeared, with heat, thirst, anorexia, and shortly after inflammatory swelling of the joints, exactly like acute rheumatism. The indigo was continued, and the inflammatory swellings of the shoulder, elbow, wrist, knee, and knuckles were removed by appropriate remedies in about a fortnight. The patient and the author ascribing the occurrence of acute rheumatism to accidental circumstances, the indigo was recommenced after a short interval. In five days the rheumatism again appeared with its former violence, and now the patient stoutly asserted that these attacks were produced by indigo. This time the swelling and pains of the joints were more obstinate, and resisted treatment longer than before. Numerous blisters were required before complete recovery was effected. As long as the articular swellings lasted (which were carefully treated, and without repressing remedies), no spasms appeared. Still doubtful whether indigo was the real cause, the author resolved on administering it a third time. He ordered it in pills to be covered with gold paper, so as to conceal the contents (the patient having previously declared her determination not to take any more indigo). The pills had only been administered eight days when the rheumatism re-appeared, and the patient at once accused the author of having administered indigo against her will. The spasmodic disease continued unabated. The stools were blue during the use of the remedy, but the urine and perspiration were normal. The patient could never take the large doses generally recommended. This was perhaps occasioned by some difference in quality of the indigo. That used in the above case was the best kind, viz., guatimata-indigo. The other kinds are impregnated with foreign vegetable substances, and perhaps also with lime, sand, and starch, by which means larger doses may possibly be taken.—(*Dr. Berger, of Brandenburg, in Pr. Vereins-Zeitung.*) The above interesting case furnishes matter for deep consideration. Credible authors assure us of the excellent effects of indigo in epilepsy; the no less credible Dr. Berger narrates to us a case where indigo most decidedly produced rheumatism. Now, the question arises, does this phenomenon disagree with the assertions of the utility of indigo? I say, positively not. I have never tried indigo in epilepsy, but the above case induces me to expect great advantage from its employment in such forms of spasm as are originated by certain digestive derangements, of course in combination with stomachic remedies. My reason is this: indigo was, in the above case, shown to attack the primary cause of the particular clonic spasms mentioned, by producing a disorder (swelling and pain of the joints) frequently proceeding from the same source. The patient being predisposed to rheumatism, the remedy diverted the effect of the morbid cause into some other organs. But in cases where no rheumatic predisposition appears, indigo may be expected to get rid of the morbid cause by the usual purifying channels, and then probably its colour would also be communicated to the urine and perspiration, as asserted by the advocates of the remedy.—*Note by Dr. Sutro.*

Peritoneal and Mammary Quotidian Pneumatosis. The author found a girl, ætat. 20, in a half-lying position on a chair, with her face highly reddened, eyes shining, abdomen distended, mammæ likewise so inflated that when the patient bent her head her nose pressed her bosom; respiration difficult, and asthmatic; pulse 95; skin dry; the abdominal swelling elastic, and unchanged by alteration of position; no induration of the intestines can be felt through it. The swelling of the breast is even, and the nipples almost obliterated. The physiological functions are little altered, except some acidity of the stomach, and slight flatulence; urine sparing, brownish-yellow, and acid; no perspiration; menstruation normal. This abdominal and thoracic inflation began regularly every morning at nine o'clock, reached its acme at midnight, and then decreased till three a.m., when the patient appeared in her natural shape. Some critical discharges of perspiration and urine then took place. The respiratory difficulty and palpitation of the heart were absent, till, at nine o'clock, without any precursory symptoms, the paroxysm was renewed. The girl had suffered four years ago from peritonitis, and such a hemorrhage from leechbites, that she lay collapsed for a considerable period. From that day the abdomen and breasts began to swell. Medical treatment, paracentesis of the abdomen, systematic compression, and a self-performed paracentesis (the patient having from despair thrust a knife into her belly), were all perfectly ineffectual, the evil only abating from time to time in its violence, particularly in winter. The typical course of this disease suggested to the author the idea of the disorder being a disguised intermittent fever, which had not been perfectly cured by the usual crises. This intermittent appeared here in the form of a periodic pneumatosis, as such developments of gas are occasionally found after suppressed fevers and evacuations, especially when critical. In consequence of this diagnosis the author ordered: ℞. quinæ sulphat, assafœtid., āā ℨj.; extr. bellad., nux vomic. spir., āā gr. iij; succ. liquir., q.s., ad. pil. 60, five to be taken three times a day. At the same time diuretics, with bitter aromatics and acrids, were administered. On account of the acidity of the stomach, bicarbonate of soda, with pulv. rhei., were also taken. The state of the patient improved considerably, and the author increased the quantity of quinine to half an ounce, which, however, was succeeded by a periodical pain under the chest, with nausea and vomiting, and obstinate obstruction for several days. The author ordered, therefore, some pills of croton-oil, a repetition of the bicarbonate of soda, and frictions, with linim. volat. camphor. on the whole abdomen and breasts. With the continued use of these remedies for six weeks the disease was perfectly removed, and the girl has regained her health and usual figure.—*Dr. Müller, of Leer, in Hanover. Annalen.*

Medullary Sarcomatous Degeneration of the Cæcum.—The patient, ætat. 44, was dropsical, and had been treated nine months ago for peritonitis in the hospital, and then dismissed cured. His face was emaciated, dark, sallow, expressive of deep suffering, respiration rather accelerated, abdomen greatly distended, fluctuating, and painful if strongly pressed on, particularly towards the right side. The intestines were tympanitic. The urine was reddish-brown; the stools liquid, two to four a day; pulse hard, from 90 to 95; skin moderately warm, and dry; the extremities covered with small dry scales; hands œdematous; the whole body very emaciated and exhausted. Inflammation of the peritoneum was suspected, of which the ascites was considered symptomatic; medullary sarcoma of the liver was believed to be the primary complaint. The patient died on the 11th May. From five to six pounds of a purulent, flaky matter were found in the abdominal cavity; the cæcum was one-third larger than usual, and, with the exception of the tunica villosa, was degenerated into a medullary sarcomatous mass, which presented the thickness of half an inch, but near the base of the valve, from three quarters of an inch to an inch. Here the medullary mass was in a state of softening, and had the appearance, like the valve itself, which was from four to six inches thick, of being melanotic. The bowels were much distended with air, and only the lower ends of the ilium and rectum contained fæces; but the cæcum was filled with yellow fluid, fæcal matter, and pieces of separated medullary substances, caused no doubt by the destroyed contractile power of this organ.—*Dr. Flogel, in Osterr. Wochenschrift.*

On Herpes Universalis and Pruritus Pudendi.—The author observed both these exanthemata in a married couple. The husband was affected before his marriage with a general herpes over the body, for which Reil, of Halle, ordered at first the external use of salt baths, but with very little benefit, and afterwards prescribed other remedies with no better effects. The author recommended a nourishing diet, and employed internally magnes. carbon., magnes. sulph., with syr. rhei. and aq. tiliæ, whilst he removed the outward scabs by covering the limbs and parts affected with sticking plaster, so that the whole peeled off, and in eighteen months the man was well. He has had no return of the complaint for thirty-six years. Before his cure, he married, however, a young woman of sanguine temperament, who was in consequence soon seized with an intolerable pruritus pudendi, which evidently arose from contagion.—*Dr. Krauss, of Gottingen, in Hanover. Annalen.*

This case should make us careful to enjoin abstinence from sexual intercourse in persons affected with herpetic eruptions.—S. SUTRO.

PROGRESS OF ENGLISH, ITALIAN, AND AMERICAN MEDICAL SCIENCE.

[The following are the only articles of interest to the profession in two numbers of the *Lancet*.]

DIFFICULT PARTURITION.—Under this title, Dr J. H. Davis narrates a case of parturition which lasted twenty-one hours and a half; the dilation of the perineum and vulva occupying a considerable

portion of that time. Laceration of the perinæum occurred at the moment when the shoulders were passing through. Inflammation and sloughing of the vagina followed, with paralysis of the bladder; the latter symptom continuing for some time after the inflammation, &c. had been cured. The patient appears, at the date of the report, to have been left with a fissured perineum.

Peculiar Case of Ossification.—Mr. Harrison states that, some time ago, he had an opportunity of seeing a very remarkable instance of departure from the ordinary process of nutrition. It happened in the person of a female, twenty-two years of age, who resided at Ancoats, near Manchester. The muscular tissue, in a great part of the body, was replaced by bone; the spine was curved, and the chest much diminished; the neck was quite rigid; the jaws could scarcely be opened, and the arms were fixed at the shoulder joints. The body was examined after death. The pectoralis on each side was completely ossified, forming bony radii, converging to a point at its insertion; the latissimus dorsi and teres major, at their conjoined tendon, were quite bony; the tendons at the bend of the arm were also bony; the scaleni and deep muscles of the neck were bony; the spine was distorted, and the muscles a mass of bone; the pelvis was of a natural size; the heart not in any way affected, and the viscera generally natural; the lower extremities were free from bone; the uterus was very small, and scarcely distinguishable, except by its triangular shape, from the surrounding membranes.

Use of Ipecacuanha in Emetic Doses as a Restorative.—Mr. Higginbottom has employed ipecacuanha, in emetic doses, in several cases of great exhaustion, in cholera, uterine hemorrhage, bronchitis, suspended animation, and sinking during the puerperal state, with advantage. In the cases of cholera, he follows up its use by blue pill and opium, and a rhubarb and sulphate of potash draught. The case of uterine hemorrhage was, apparently, very severe; the full emesis produced by the ipecacuanha arrested the hemorrhage, which, on subsequent occasions, was prevented by the exhibition of secale cornutum. He objects to diffusible stimuli in such cases, as he believes they increase the arterial circulation, and, consequently, the hemorrhage. In bronchitis, Mr. Higginbottom has found an emetic dose of ipecacuanha a very valuable remedy in that stage of bronchitis where a sudden, low, or sinking state has come on, with oppression at the chest, and the expectoration difficult, endangering suffocation.

Tic Doloreux.—Mr. Gower says that the extract of tobacco will cure neuralgia so that it shall not return, and this with once using.

Perforation of the Duodenum.—Dr. Little narrates the particulars of a case of chronic ulceration of the duodenum. The patient, a gentleman, fifty-seven years of age, was suddenly seized with intense pain in the abdomen, increased by pressure, referred principally to the region of the ascending colon and epigastrium, afterwards to the left side of the umbilicus. Some slight reaction ensued, but the patient sank, and died twenty-four hours after the attack. The examination of the body showed severe peritoneal inflammation, caused by the effusion of a pint of dark turbid fluid through a perforation of the duodenum, immediately below the pylorus. Towards the abdominal cavity, the aperture was oval, one-third of an inch in its longer diameter. Towards the intestine the ulceration was triangular in form, with largely elevated and rounded margins. The ulceration, previously to the peritoneal wall giving way, had formed a *cul de sac* behind the pylorus, capable of admitting the extremity of a finger. The pylorus was thickened, but preserved its natural firmness. No other disease was observed in the abdomen, which alone was examined. Dr. Little considers that this case must be classed as one of simple chronic ulceration of the duodenum, destroying life by perforation.

New Instrument to remedy the Defect of Speech consequent on Congenital Fissure of the Soft Palate.—Mr. Stearns having a relation afflicted with congenital fissure of the soft palate, on which the operation of staphyloraphy had been twice performed unavailingly, and for whom dentists had exhausted their mechanical skill, contrived an instrument to remedy the defect, the application of which has been attended with satisfactory results. A gold plate is first fitted to the roof of the mouth, in the manner practised by dentists, which is to serve as the foundation or support of the mechanism intended to supply the want of the natural soft palate. To the upper and posterior margin of this plate, a flat spiral spring is attached, which, with the delicate and permanent elasticity peculiar to that kind of spring, admits of easy and constant vibrations backwards and forwards. To the other and posterior extremity of this spring, an artificial *flexible* velum is attached. This part of the instrument is constructed of Mr. Goodyeare's preparation of caoutchouc, which, having the property to resist the action of both oils and acids, and at the same time sustaining a high degree of heat, has proved well adapted to the purpose. In attempting to describe the artificial velum, he, for the want of better terms at present, designates its principal parts as its *body* and *wings*. The body of the velum consists of a lamina of the caoutchouc, of a somewhat triangular form, and of the same size and shape as the vacant space it is intended to occupy, that being the plane which would be indicated by imaginary lines connecting the opposite sides or columns, and subtending the vertical angle of the fissure, at which point the velum is connected to the posterior extremity of the spiral spring. This lamina, constituting the body of the velum, is divided into three pieces, which overlap each other. The wings project obliquely forwards and outwards from each lateral margin of the body, and being made to conform to the shape of the columns or sides of the fissure, are seen to rest upon their inner and anterior surfaces, thus covering a portion of the soft parts which constitute the boundaries of the posterior fauces. In like manner, along each lateral margin of the body, there is (in mechanical phrase) a flange, projecting obliquely backwards and outwards, and, extending along down the posterior surface of the column, it terminates at the inferior angle of the velum. In this way the wings and the flange, on the same side, together form a groove fitted to receive the fleshy sides of the fissure. As the preparation of caoutchouc made use of presents a smooth surface, and yields readily to the slightest pressure, it is found to permit the contact and muscular motion of the surrounding soft parts, without causing any irritation. When, therefore, the sides of the fissure tend to approximate, as in deglutition, gargling the throat, or the utterance of some of the short vowel sounds, the three parts of the body of the velum slide readily by each other, thus diminishing the extent of exposed surface, and thereby imitating, to some extent, muscular contractile action, the force being derived from without, and not, of course, contained within the instrument. During the effort made in speaking, the surrounding muscular parts embrace and close upon the artificial velum, and press it back against the concave surface of the pharynx. The passage to the nares being therefore temporarily closed, the occlusion of sound is accomplished, and articulation made attainable, as the voice or sound, as it issues from the glottis, is thereby directed into the cavity of the fauces, and confined there long enough to receive the impressions made upon it by the tongue, lips, &c., in the formation of the consonant letters. Though the instrument, after having been adapted in the way above described, was found materially to improve the speech, yet it was still considered defective, and not admitting of general application, until other important requisites had also been attained; for it was necessary to make it so yielding as not to irritate the sensitive and restless parts with which it must come in contact; so that it might at all times be retained in place without inconvenience, while eating, drinking, or during sleep. At the same time, it was required to possess a degree of strength and firmness sufficient to sustain the force of any sudden shock, as in coughing, sneezing, or laughing, without the risk of being displaced, or in any way deranged. Durability of the substance composing the velum was also regarded as a point of the first importance to ensure its usefulness. The material made use of, as prepared by Mr. Goodyeare, and managed according to his instructions, was found (after some practice in the manipulation necessary to bring it to the shape required) to resist the combined action of all the decomposing agents to which it must become subjected—viz. motion, animal heat, the moisture and acids of the mouth, and the oils of the food. The means afterwards devised to keep it in order, freeing it from deposits, and thus preventing fetor, consist in the occasional use of some alkaline or aromatic preparation. As cases of congenital fissure vary very much, it follows, as a matter of course, that some modifications of this instrument will not unfrequently be required.

Priapism.—Mr. Tripe describes a case of intense and long-continued priapism, occurring in the person of a young seaman, which came on during the night of the 26th of April, 1844, attended with pain of the left side of the organ, near the bulb, and an inclination of it towards the same side. Mr. Tripe, on examination, found the corpus spongiosum moderately turgid, especially the gland, which was situated near to the anterior superior spinous process of the ilium, and almost touching the abdominal parietes; the corpora cavernosa were fully distended and firm, scarcely yielding to pressure, and without any perceptible difference, either in colour or firmness, at the part from which the inclination towards the left side commenced. When its restoration towards the median line was attempted, the pain was much increased. The treatment adopted by Mr. Tripe consisted in the application of leeches and cold lotions, and the exhibition of tartarised antimony and opium, with occasional purgatives internally. By these means the priapism was much reduced, and the patient relieved; but the disease returned as violent as ever, in consequence of the man's imprudence, in having had intercourse with women repeatedly, and Mr. Tripe, therefore, sent him into the London Hospital, where he was bled, and leeched, and purged, and had spirit with lime water applied to the parts. After this he was salivated with some benefit, when he left the hospital against the wishes of the surgeon. The penis was then more flaccid, and formed a right, instead of an acute angle with the pubis. After this the man had connection repeatedly, erection of the penis taking place to the full extent, and afterwards gradually subsiding to the state in which it was previously to the venereal orgasm. The man afterwards left England for Sydney, the corpora cavernosa continuing moderately tense, and forming an angle of about forty-five degrees with the pubis. This state lasted for above three months longer, and then gradually disappeared. Mr. Tripe considers that the lesion was caused by effusion of blood into the cells of the corpora cavernosa, which remained in a semi-fluid condition.

Hæmatemesis, and Purulent Infiltration of the Right Lung.—Mr. Smith narrates a case of hæmatemesis, with purulent infiltration of the right lung, terminating fatally, in a man, who, while recovering from the effects of a suppurating gland in the axilla, which had left a troublesome sinus, had indulged in some unwonted convivialities. On examining the body after death, the mucous membrane of the stomach and intestines was of a purplish-red colour, and very easily detached from the neighbouring tissues; they were filled with dark-coloured semi-coagulated blood. No ulceration, with the exception of a most minute one at the pylorus, could be detected throughout the whole track. There was some degree of hardness about the muscular fibres of the pylorus, but it could be hardly said to amount to scirrhus; the liver was much enlarged, and presented an engorged appearance; the right lung was, throughout its whole extent, infiltrated with pus, and so soft that it would easily break down under the finger; in fact, in that stage of pneumonia which some pathologists have denominated "yellow hepatisation."

Inspissated and Desiccated Ox-gall.—Dr. Hunter Lane says, with a view to preparing ox-gall for internal administration, care should be taken in selecting perfectly healthy gall bladders of young oxen. Persons in the habit of collecting this recent gall for pharmaceutical purposes, find, on comparing the bladders, a striking difference in their contents, not merely as affected by the period of year, nature of the animal's food, and the beast's age, but in oxen killed at the same season, after being similarly fed, and of a corresponding age. The frequent occurrence of morbid admix

tures with the gall, varying from thickened mucus to purulent deposits and calculous formations, render proper discrimination imperative; otherwise, after carefully preparing a quantity of recent gall, disappointment will succeed the process, because negligence may have mixed up with the fluid the abnormal product of a diseased liver, which, on evaporation, converts the whole into a disagreeable, putrid mass, totally unfit for use, and quite different from the character of the somewhat aromatic animal mass which results from the evaporation of normal ox-gall. Healthy fresh ox-gall is a transparent fluid, of a bright, dark, grass-green colour; of a viscid, tenacious, equal consistence, of a strongly animal with slightly aromatic odour, and bitter alkaline taste. Bile of this description, taken from about a dozen bladders, should be poured into a deep earthenware vessel, and allowed to rest for about twenty-four hours; the supernatant fluid should be then poured into a shallow dish, such as an ordinary meat dish, and set into an oven, the temperature not exceeding 100 F., until the whole be reduced to the consistence of a pharmacopœial extract. Thus it is *inspissated* ox-gall, and easily made into pills. After employing it in this state for some time, experience showed the inconvenience which its highly deliquescent property entailed. For, kept ever so carefully, it soon became too moist to use—a difficulty which evaporating it in mixture with magnesia did not satisfactorily remove, while it so augmented the bulk of the substance as to disqualify it for employment in a pillular form. When rolled into pills, and buried in magnesia or powdered liquorice-root, or enveloped in silver or gold leaf, and put into well-corked phials, it still absorbed moisture, and they soon conglomerated into one mass. To obviate this troublesome difficulty and serious objection, as it proved, to the more extensive use of this invaluable remedial agent, Dr. Lane suggests that, instead of the gall being merely *inspissated*, it should be *desiccated*. For this purpose, it needs only to be allowed to remain at the same temperature, until there remains a dry, bright-green, friable, pulverulent, slightly aromatic mass; in which state the substance loses none of its medicinal virtues, its deliquescent character is nearly lost, it can be easily preserved in closely-stoppered bottles, and is with facility made into pills, particularly with any spirituous fluid, or essential oil, and will mix well with various salts that are otherwise not readily made into pills, while it is, where desirable, with facility mixed with other materials into powders.

REVIEWS.

Lectures on Subjects connected with Clinical Medicine, comprising Diseases of the Heart. By P. M. Latham, M.D., Fellow of the Royal College of Physicians, Physician Extraordinary to the Queen, and late Physician to St. Bartholomew's Hospital. London: Longman and Co. 1845. In 2 vols.

This is an extraordinary book; it gives us an English hospital physician in the new phase of a thoughtful, scientific man—original at times, daring often, interesting always. Dr. Latham's resignation of St. Bartholomew's hospital was always felt a loss; and these lectures, though the fruits of the leisure thus secured, rather enhance than mitigate the feeling of regret. We could well wish that other physicians enjoying the rich opportunities furnished by our larger hospitals, had the high mental cultivation, or great industry, that would enable them to make as fruitful use of them as Dr. Latham. We should then turn to our English medical appointments with less of that shame which ever rises to the English countenance while discussing with foreign *savans* the relative claims of London and Paris medical celebrities. But the system is so faulty, that the wonder is, not that London, with its two millions of inhabitants, furnishes so few surgeons and physicians distinguished by original and profound research, but so many. Having a good book for once before us, we will show our appreciation of it by a very minute abstract.

The lectures contained in this, the first volume, are seventeen in number; they are devoted to the consideration of the normal sounds and impulses of the heart, inflammation of that organ, endocarditis,—pericarditis, and its causes and complications, principally acute rheumatism—the action of mercury in the treatment of inflammation—and, finally, endocarditis and pericarditis, independent of rheumatism. As these are all matters of the greatest importance to the medical practitioner, we shall proceed to analyse each of these lectures *seriatim*.

The first lecture contains Dr. Latham's views respecting "*the natural sounds and impulses and resonances of the heart*;" and "*how their variations of degree and extent become evidences of the heart's disease and unsoundness*." It commences by a quotation from Dr. Hope's great and elaborate work on "The Diseases of the Heart and Great Vessels," in which is accurately defined the exact situation of the præcordial region, where the signs yielded by auscultation and percussion, immediately referable to that organ, are to be sought for:

"Within this space we cannot see. But at this space we can listen, and feel, and knock, and so put it to question, whether all be right beneath. And there is no spot of it which does not in its turn make answer to the ear, to the touch, or to the tapping of the finger, and tell something of the organ that lies herein. Hence proceed sounds, some of health and some of disease, which of the two the ear must judge. Hence are conveyed impulses, some of health and some of disease, which of the two the touch must tell."

The sounds that are heard by auscultation are produced by the vital movements of the heart; to those elicited by percussion, that organ only contributes as an inert mass. The first set of sounds are those which are first described by Dr. Latham:

"In listening at the præcordial region, the ear at once perceives two sounds proceeding from the heart,—the one duller and more prolonged, the other clearer and shorter; the one coinciding with the systole of the ventricles and the pulsation of the arteries, the other coinciding with the diastole of the ventricles and the rest of the arteries. Hence it appears that for one pulsation of the arteries there are two sounds of the heart.

"But between the two sounds of the heart there is hardly an appreciable interval. The duller sound, which goes for the first, seems to end with a snap, which goes for the second; and then succeeds an interval of repose, which is appreciable enough, before the duller sound returns.

"The time thus occupied by the sounds of the heart in their succession and their pause, has been divided and accounted for after this manner:—one half is filled up by the first sound, one quarter by the second, and one quarter by the pause.

"Still, though there be hardly an appreciable interval between them, the ear acknowledges two sounds."

The first of these sounds is supposed to be produced by the muscular structure of the ventricles, and the auriculo-ventricular valves, the muscular structure by its contraction giving it length and dulness, and the valves giving it a perceptible sharpness by their extension. Together with these, there is said to be a third element, which is called the muscular tension of the heart. It takes place when the blood is poured in from the auricles, the valves are closed, the ventricles filled, and their muscular fibres braced up, so that the entire mass becomes for a moment as hard as cartilage. It appears that, according to this theory, there are three sounds occurring simultaneously in the first sound of the heart; a piece of information of some value, probably, in a physiological point of view, but for practical purposes the sound may be considered as single, and as produced by one cause, viz., the muscular contraction of the ventricles.

The efficient cause of the second sound is in no way connected with the relapse of the ventricles from a state of tension to that of flaccidity, but is caused by the sudden closure of the sigmoid valves by the recoil of the blood, when it is thrown back upon them from the pulmonary artery and the aorta. The natural and healthy limit of the heart's sounds within the chest is not precisely defined by the præcordial region. The second sound, as might be anticipated from its being produced by the aortic and pulmonary valves, always exceeds it, and is audible in the course of the aorta, pulmonary artery, and carotids:

"With respect to the first sound, (says Dr. Latham) I should be at a loss to mark the exact space within which healthy proportion and healthy structure always required it to be heard, and in neither more nor less. There are so many circumstances, some consistent with health in the largest sense, and some exclusive at least of its disease, which make the systolic sound of the heart more or less extensively audible, that (I am persuaded) two healthy persons would not easily be found in whom it would be heard exactly within the same thoracic space. Whether a man be fat or lean will always make a great difference. In the one it will be kept within the præcordial region, in the other it will be carried beyond it. Fat is so bad a conductor, that where it greatly abounds, it will restrict the sound to less than the entire præcordial region, even to a very small part of it, so that you will not be able to hear the heart further than you can feel its impulse, or not further than its apex. But mere skin and bone are such good conductors, that in very thin persons the sound will spread very far beyond the præcordial region, and may be heard at any part of the chest to which you apply your ear.

"I believe that in most persons of (what is called) a nervous temperament, even when they are under no conscious excitement, the heart's sounds are to be heard beyond the præcordial region, and, under actual emotion, very far beyond it. And I believe too that in persons of this temperament the heart's sounds are apt to be of a higher intonation. One condition, no doubt, is the result of the other. In proportion as the sounds of the healthy heart are more highly intonated, they acquire a greater audible extent. The louder they are, the further you hear them. And it is the very characteristic of a nervous heart to have its sounds both highly intonated and extensively audible.

"The greater extent and louder intonation of the heart's sounds may be no direct symptoms of disease or unsoundness in the organ itself; but they may be, and often are, indirect symptoms of disease or unsoundness appertaining to other parts within the chest. Whatever gives more than their natural solidity to the contents of the chest; pulmonary deposits, inflammatory or tubercular; thickened walls of vomicæ, a thickened pleura and fluid within its cavity, aneurismal tumours, and foreign growths and curvatures of the spine; all these, partly from the compression which they exercise upon the lungs from within or from without, and partly from the amount of solid matter appertaining to themselves, give to the sounds of the heart a larger audible sphere within the chest, and exalt their natural intonation.

"It is well to be aware of all this. Not that the heart's sounds, by their greater audibility and extent, can do more than intimate the possible existence of some such forms of disease. The diseases themselves are discoverable by their own direct signs, and there is no need of questioning the heart concerning them. Only we should take especial care that what from extrinsic circumstances seems wrong about the sounds of the heart, be not wrongfully brought in evidence against the heart itself."

The impulse of the heart must be ascertained by the touch; its efficient cause Dr. Latham, rejecting the finely-spun theories of physiologists, would refer solely to the contraction of the ventricles. Its normal limit is better defined than is that of the sounds previously described; nevertheless, it is materially modified by position. In a man standing up, it is felt just where the apex strikes the chest at a point between the fifth and sixth ribs, and not beyond it. If he be leaning forwards, it is felt at this point and a little above it, and also in the direction of the sternum. It becomes almost or altogether imperceptible if he be reclining on his back, or right side; but if he be on the left side, it is more perceptible than ever, and in a somewhat larger and different space, between the fifth and sixth ribs, and thence more towards the mamma than the sternum. The limit of the impulse is modified also by other causes, such as redundancy and want of flesh, and the proximity of consolidated

structures, and also by the nervous temperament, as are the sounds already alluded to.

The part selected for percussion is a circle, the centre of which is a point midway between the junction of the fifth costal cartilage on the left side with the sternum and its junction with the rib, that circle being two inches in diameter. This circle will as nearly as possible define the space of the præcordial region which is naturally less resonant to percussion than the rest. Here the heart is uncovered, except by the pericardium and a loose cellular texture, and may be said to be in contact with the walls of the chest; while in the rest of the præcordial region it is covered, and separated from the walls of the chest by the intervening lung. The sound elicited by moderate percussion is rather that of diminished resonance than of positive dulness. The latter is only obtainable by that degree of percussion which shall be absolutely painful to the patient:

"It is well to be aware, that the erect posture is more favourable than the recumbent for making this dulness or diminished resonance perceptible to the ear; and the instant of expiration than the instant of inspiration. In the recumbent posture the intervening loose cellular texture is not strong enough still to keep the heart close to the sternum and the ribs, and prevent its receding by the force of gravity. And during inspiration either a larger portion of lung may be brought in front of the heart; or the portion which is always in front of it may be so thickened by inflation as to thrust backward, for the time, more of the heart than it actually covers."

Hitherto the sounds, impulses, and resonances of the heart have been regarded only in degree and extent. The two latter, indeed, do not vary otherwise, but the sounds admit of varieties in kind also. From the variance in degree and extent of the sounds, impulses, and resonances of the heart in health and disease, we are enabled to gather important information respecting its condition:

"A clearer sound proceeds from a thin heart, and a duller sound from a thick heart; a sound of greater extent from a large heart, and a sound of less extent from a small heart. A more forcible impulse is given by a thick heart, and a feebler impulse by a thin one; the impulse is conveyed to a longer distance from a large heart, and to a shorter distance from a small heart."

In considering these matters, we must not take any one set of symptoms *per se*, as both sounds and impulses are capable of becoming augmented and lessened by extrinsic causes:

"But, happily, sounds and impulses are the interpreters of each other. The true meaning of the sound is tested by the impulse, and the true meaning of the impulse is tested by the sound.

"Thus, from a clearer sound, we argue only the probability of an attenuated heart; but we argue its certainty from a clearer sound joined with weaker impulse. From a stronger impulse we argue only the probability of an hypertrophied heart; but we argue its certainty from a stronger impulse joined with a diminished sound.

"When impulse and sound increase together, there is probably no hypertrophy, but the heart is only acting more forcibly from pure excess of nervous energy. When impulse and sound decrease together, there is probably no atrophy, but the heart is only acting more feebly from pure defect of nervous energy.

"When the sounds and impulse of the heart are both perceived beyond the præcordial region, they give notice (generally speaking) of dilatation of one or other of the ventricles. If, under these circumstances, sound predominate over impulse, then with dilatation there is either attenuation, or somewhat less than a proportionate increase of its muscular substance. If impulse predominate over sound, with dilatation, there is either hypertrophy or somewhat more than a proportionate increase of its muscular substance.

"Thus it is seen how much information respecting many the most important structural changes, which the heart is liable to undergo, may be conveyed merely by the greater or less intensity, and by the greater or less extent, of its sounds and impulses."

Percussion is of but secondary importance, and can only be regarded and used as an auxiliary to auscultation:

"Percussion may find the whole præcordial region dull, and much more than the præcordial region. The dull space may extend beyond it laterally and reach from mamma to mamma; or it may extend upwards, and reach as high as the second or even the first rib on the left side, and thence, spreading beneath the sternum, reach nearly as high on the right. And all this may be caused by the heart enormously enlarged in all its dimensions. The heart, as it goes on enlarging, pushes the lungs aside, and comes itself almost in complete contact with the walls of the chest anteriorly. Still it may not be caused by the heart, but by solidified lung, or by pleural effusion, or by an aneurismal tumour, or by some vast morbid growth. By which of them, however, percussion alone cannot decide."

Still, however, percussion has its value, and not unfrequently aids the auscultator when on the track of disease, and confirms and assures his diagnosis:

"Whatever forms of disease or unsoundness have the effect of augmenting the general bulk and compass of the heart, lie especially within the reach of percussion, and within the possibility of deriving illustration from it. Diseases which issue in superadded substances, in serum or lymph, or pus or blood, accumulated within the pericardium; forms of unsoundness which consist of thickened muscular structure, or more capacious cavities, or of dilatation with hypertrophy, or dilatation with attenuation, all admit of being better understood by help of percussion."

(To be continued.)

Compound Fracture of the Femur.—At a meeting of the Newton branch of the Provincial Medical Association, Mr. Barrow related the particulars of a case of compound fracture of the femur, which occurred in a sailor, nineteen years of age. He fell from one of the masts of the Great Western steamer, a height, as it was reported, of sixty feet, alighting on the deck, and fracturing his left thigh; a considerable wound was the consequence, and a portion of the femur, about an inch and a half, was detached, and left firmly fixed in the deck. This piece of bone consisted of about two-thirds of the cylinder, the remainder being afterwards found in the wound. The accident occurred at sea; the boy was consequently removed to his hammock, and treated as well as circumstances would allow. After four days he came under treatment upon land, not having suffered more constitutional disturbance than might have been expected. The usual remedies were had recourse to, both mechanical and otherwise, and in due time the wound healed to about the size of half-a-crown; the bone became firmly united, without any very great shortening of the injured limb. From this period, (which was about six weeks after the accident,) until his death, which occurred at the end of four months from the time of his landing, he was attacked by frequent severe pain, inflammation, and swelling of the whole limb: large abscesses formed, and quantities of pus were, from time to time, discharged by incisions. A probe passed in at the original opening, discovered the roughness of bone denuded of its periosteum, and subsequently a loosened portion was detected. No attempt was made to remove this. After death, several pieces of bone which were exhibited to the meeting, were removed. They constituted the remaining portion of the cylinder which was broken off at the time of the accident, and a considerable piece of which was fixed in the deck of the vessel. They were doubtlessly the cause, by the irritation they induced, of the great pain which was experienced, and of the swelling and large abscesses which followed, and led to the patient's death by exhaustion. Their removal might have been attempted when it was found that portions of bone were denuded of periosteum, and the patient might then have had a chance of life.

NOTICES TO CORRESPONDENTS.

Important.—*Several subscribers, in arrears, are requested to forward immediately the amount of their accounts, in order that their names may not be placed in our list of defaulters.*

Anatomist.—*Assistant-surgeons for India must be over twenty-two. The attempt to procure an appointment by purchase would subject all the parties concerned to the penalty of a misdemeanour.*

A Student.—*Apply to the Rev. Dr. Lee, the President of the University of Edinburgh.*

W. L.—*We are not aware whether the school named will be revived this year or not.*

Medicus Anglicanus.—*The terms of Trinity College are three. The next (Michaelmas) will begin October* 10.

A Constant Reader (Bath).—*The most recent work on Dysmenorrhœa is Dr. Rigby's. It is needless to say that it is also the best.*

An Old Admirer.—*There is a school of medicine at Rouen, but it is only a preparatory one. Parchappe is the professor of physiology. The terms are moderate, but we cannot say precisely their amount.*

A Three Years' Subscriber.—*We are not tooth-stoppers, and, therefore, may be considered bad authorities on the subject. We incline, however, to the opinion that there is nothing like gold. The constituents of several amalgams, more or less useful, have been published in former numbers (and within* "three *years"), and others have been noticed in our Pharmaceutical Numbers, the whole series of which (fifteen numbers) may be procured from a bookseller for six shillings and threepence.*

A Constant Reader *attacks Alpha's defence of h advertisement. Our correspondent is indignant that Alpha should ask the requirements of a valet from the member—however indigent—of a gentlemanly profession. If that were justifiable, it would have been equally right to have asked the* "*Medicus*" *to perform the functions of a chimney-sweep, provided only that, in the words of Alpha, the salary were as good as a curate's. In quitting this subject, we have only to say, that the degradation of the medical profession is shown by the fact, that such an advertisement could be addressed to it by one who imagined, and we doubt not sincerely, that by it he was doing the profession a service. How, as our correspondent asks, would such a notice have read, addressed* "*To the Legal and Clerical Professions!*"

M. B., *we regret to say, will be excluded from the competition for our clinical prize reports.*

A Correspondent *reminds us that the Apothecaries' Society consider their protective or restrictive clauses as a* "*dead letter,*" *under the present uncertain position of the whole profession; and that medicine is now practically open to any ignorant and unprincipled pretender who thinks proper to dabble in it. Our correspondent justly traces this evil to the doors of those who did their utmost, by all kinds of false pretences on one side, and calumnies on the other, to breed the appearance of dissension in the profession, and so postponed the passing of a bill which would have established an independent faculty of surgery and medicine, governed immediately by the profession itself, and having full power and the most zealous inclination to suppress quackery.*

Several communications (which were received last week) are unavoidably postponed by press of matter.

Query *is inadmissible, but has our thanks. The* "*seven first numbers still on sale*" *are likely long to enjoy the privilege. The falling-off on all sides is extraordinarily great, we are assured. That alone is sufficient punishment.*

A Constant Subscriber.—*We think not; but our correspondent should address the secretary, Mr. H. Blatch.*

A Four Years' Subscriber *would probably meet what he seeks in the Glasgow Faculty of Physicians and Surgeons, and should consult Dr. Weir on the subject.*

D. S. S.—*The first of October will be the last day on which we can receive reports competing for the Medical Times' Prizes.*

Mr. Searle's *communication has been received.*

An abstract of Dr. Wolff's *paper has already appeared in the* Medical Times, *in the reports of the* Parisian Academy of Sciences.

Dr. Protheroe *Smith's communication has been already noticed.*

Our correspondent from Chatteris shall be noticed.

A Practitioner of two tails *will be published.*

Mr. Greave's *report shall appear next week.*

A number of papers not acknowledged are respectfully declined.

A Committee-man *sends us a long communication, in which he soundly rates us for turning the subscriptions, proposed to be used to pay off the damages in the late action, to a purpose distinct from the donors' intentions, viz., the foundation of prizes. He asserts that the profession, which would come forward handsomely for the one purpose, "as evincing properly their strong sense of the nature of the action of libel, will not feel called on to contribute to what is, after all, but a prize endowment fund." Our only reply is, that either course is open to the profession; but that we could not consent to receive subscriptions for a matter in which the damages were of such trifling import, and which referred to a matter so entirely personal to ourselves.*

The old copy of a contemporary sent us by a friend will not be overlooked.

THE MEDICAL TIMES.

SATURDAY, AUGUST 23, 1845.

L'union fait la force.

WE last week referred in terms of disappointment and sorrow to certain omissions in the Government bill. We pointed out that the deputation of the National Association had distinctly stipulated (and successfully) for terms which did not appear in the subsequent Parliamentary measure, and we ventured an opinion that the omission originated in an oversight. We are this week fortunately enabled, on authority of the most undoubted character, to promulgate the fact, that the difference which appears between the clauses of the new bill and the report of the deputation was wholly accidental; that it arose from the difficulty of settling what should form provisions exclusively of the new Charters, and what should be definitively named in the Parliamentary measure; and that on the first possible moment the bill will be so verbally altered as to correspond exactly with the understanding come to by the deputation.

We need not say that we rejoice in this result. It relieves us from the unpleasant suspicion that this (in Byron's words) was that

"kind of a discussion—
A sort of treaty between the British Cabinet and '*Profession,*'
Maintained with all the due *prevarication*
With which great states such things are apt to push on;"

and removes the fear that Government are disposed to stretch a point or two under the instigation of the old corporations. But the great fact of all is, that it gives us a certitude that a first practical step will be actually made at the beginning of the next session, by the only party in the House that can effectually take it, towards the governmental amelioration of our Profession. That first step, it is true, will fail to be as extended as we could wish; it will not fulfil the whole of the wishes of the great majority of the Profession, but it is something to say that a first step will at length really be taken; it is something to be sure that we are to have a change, the shortcomings of which, if they exist, will be quickly shown by actual experience, and thus enforce, by the best of arguments, the further journey wise policy would indicate as necessary. A career of change once commenced, the only hope of an arrest is the certitude that the first step is complete.

It is not now the time to discuss the question whether the deputation could have secured better terms from the Home Secretary. It is highly probable, that pressed as that statesman was by the double opposition of the Colleges of Physicians and Surgeons, partially aided by different Scotch and Irish Institutions, he would have abandoned his measure utterly if the compromise at last conceded by the deputation had not been agreed to. But the question *now* before us assumes *another* shape. The question for us to consider is, whether that agreement *having been made*, it is our policy to confirm it. Our own opinion is, that if the arrangement made with the deputation be carried out in full integrity—as it undoubtedly will be—it will be more politic on the whole in the Profession to sanction the enactment of the changes it offers us, rather than oppose it to rejection, and fling ourselves on the chances offered by a prolonged medical agitation.

We frankly own that we are full of hopefulness of the zeal and pecuniary liberality of the Profession, in supporting any highly respectable organisation which could give us the chance of forcing a good bill through Parliament, despite the opposition of the old corporations, and notwithstanding the coldness or hostility of Government. We even believe that if the Committee of the National Association were obliged by circumstances to assume a position of declared hostility to the present bill, if countenanced by a *general* support, they felt compelled to oppose the existing systems, and to denounce the scheme of Government as a mischief, they would be enabled not only to defeat the Government measure, but to establish a National Faculty, which would, at no very distant day, extort from Parliament a statutory recognition. But at present we are not in these circumstances. While they, on the one hand, do not feel compelled to take up this position of hostility, there could, on the other, be no united organisation *against* the specific terms agreed to by the deputation. The majority of the Profession would agree on their acceptance—would not sanction their rejection—and the Committee itself, consisting of so many members, all thoroughly respectable, all independent, and all from different districts in the kingdom—the Committee, we say, in acceding to the arrangement, have shown that, as a rule, the bill would be generally taken as one of those compromises which—the less of two evils—would be eagerly preferred.

It need not be said that, next to the advantage of that perfect bill of Medical Reform which is hardly in the range of possibility, is a perfect agreement and union among the members of the Profession. Now if, on Sir James Graham making his bill echo his agreement with the deputation, the universal feeling be, "There is a general consent to the bill: it can be passed without difficulty: let it succeed, in order that we may see what it will do for us: it cannot do harm, and we will try its capabilities of doing good;"—if thus speak the Committee, if thus speak the great mass of the Profession, the obvious duty will be for the minority to defer to the expressed sentiments of the majority, with the view to merge subsidiary differences in the policy of a general union, to check the discord which would weaken our defence, and promote the cordial unanimity that alone, at a trying moment, can strengthen our influence. If there be some dissentients—as we can well understand there may be—it will be their pleasure, we are sure, to avoid the discredit and mischief of ineffectual dissension by postponing their objections, which can do no service, for that time when experience may show the worth of their prognostications.

We have ourselves some doubt whether the great objection we feel to the arrangement of the deputation will be one sympathised in by the Profession. The anxiety among a great portion of General Practitioners to retain a connection of some sort with the College of Surgeons is so strong, that most will view with satisfaction the requisition of a second examination, and the payment of a second fee. Men are naturally more anxious about the high scientific standing of the new brethren introduced to them than about the unfettered independence of their College. We are too apt to say, "Educate the candidate for my class of practice as highly—examine him as often—give him as many diplomas—charge him as dearly as you please! Support the high science and standing of my order, and it is of little consequence by what collegiate means you effect it." There is much practical wisdom in this view of the subject, and though our leanings are rather towards raising the Members by the College, than the College by the Members, it is impossible to deny that, in reference to actual social consequence, the bill is left by the deputation in a state most favourable to the class of General Practitioners. The General Practitioner, at once a Member of the New College, after a long course of studies, and with distinguished examiners, and then, by a second examination, a Member of the College of Surgeons, will stand before the public as a man whose scientific skill will admit of no moment's doubt, and will be no inconsiderable opponent for persons who, on the strength of one examination, and that not a very remarkable one, affect to claim a higher social and professional position. The Colleges of Physicians and Surgeons, indeed, in their schemings for the fees of a second examination, have sacrificed the interests of their Physicians and Pure Surgeons. They have won collegiate pre-eminence at the expense of the scientific repute of their *alumni*. The fees of the Physician and Pure Surgeon will diminish exactly as increases the wealth of their Institution. The General Practitioner, examined by his own college-heads (who will not be undistinguished), examined by the Pure Surgeons, and examined by the Physicians, will be a formidable competitor for practice.

DEATH OF DR. DE BEAUMONT.

It has rarely fallen to our duty to record a bereavement which has filled us with more regret than that of Dr. Garland de Beaumont, which took place, in the prime of life, at Paris, on the 8th instant. We enjoyed the honour of having him for some years as our French correspondent, and our readers can bear witness to the zeal, industry, and judicious taste with which he laboured for their instruction. He was ever at his post. During the whole time of his connection with us there was not the break of a single weekly communication. His services to the *Medical Times* were great, and will always be deeply engraven on our memory, and acknowledged with gratitude. He was an M.D. of the Parisian Faculty, of highly respectable practice, and held an honorary appointment in connection with the Spanish embassy in that city. A learned practitioner, a worthy and honourable friend, he proved the goodness of his heart as the sole stay of a fond mother and admiring sister, who are left by his decease wholly without provision.

NATIONAL ASSOCIATION OF GENERAL PRACTITIONERS.

In our last number we referred to the elaborate and excellent Report of the Committee reviewing the medical labours of the past parliamentary session. We propose now to submit a full abstract of the contents of that document.

The Committee commence by observing, that the Bill introduced by Sir James Graham in August, 1844, was introduced by the sanction of the English, Irish, and Scotch Colleges of Surgeons and Physicians, while the body of General Practitioners and Society of Apothecaries were wholly overlooked in reference to it, and not once in any way consulted. In a corresponding spirit was the Bill framed; the General Practitioners were annihilated as a high grade in the profession. The National Association opposed the Bill, and it was not pressed.

The meeting of December took place; the Association was recognised by Government as the organ of the hitherto overlooked body of General Practitioners, and though Government distinctly expressed its intention to uphold the existing institutions in full integrity, it nevertheless showed itself inclined to lend the utmost weight to the representations of the new body. The Minister avowed that the project of making the College of Surgeons a College of General Practitioners would never have his sanction. It would also be opposed by the College of Physicians, who would not consent to see its rival made practically a College of Physic. The project was also equally objected to, which schemes the Institution of the General Practitioners into a Faculty of Medicine and Surgery. It is declared to be a scheme that would ruin the other Colleges and supersede the Universities. The question of a connection between Medicine and the Universities is then discussed, and the Committee conclude, that while on the one hand our Government would not deprive the Universities of an influential relation to Medicine, on the other hand it is not expedient that it should. The Committee proceeds :—

"To convert the College of Surgeons into a College of Medical and Surgical Practitioners (general practitioners) or to institute a new College of General Practitioners in medicine, surgery, and midwifery, upon the representative principle, under royal charter, *totally* independent of the existing colleges, would be regarded by the government and the legislature, under the influence of the colleges, as having such a tendency. The Committee give no opinion in this place on the *one faculty* question, but the most influential parties have clearly indicated, that they would regard either of the arrangements just referred to, as tantamount to the establishment in this country of *one inferior Faculty of Medicine*.

"Had the Minister limited himself to this view of that part of the question which relates to the connection of the medical profession with the universities—determining not to lend himself to a measure which would lead to the establishment of one inferior faculty, by discouraging a university education,—that alone would not have induced him to frame the provisions of the first bill, by which the general practitioners were regarded as mere 'vendors of medicine,' and subjected to the most complete measure of degradation. The Minister could not at the time have been aware, that nine-tenths of the profession were necessarily general practitioners—that it is impracticable for the majority of the profession to be university-educated men and consulting practitioners—that to degrade the general practitioners as a class, is to degrade the whole profession—that the public weal demands on the part of every man who pretends to the practice of physic and surgery, a high standard of medical and surgical qualification, apart from the university standard of qualification in classics and mathematics for the degree of M.D.—and that it is a great desideratum in this country that the scientific energies of the profession at large should be called into activity, instead of being smothered as heretofore by corporate exclusiveness."

The Association so effectually impressed these truths on the Minister's mind, that in May he gave to the world what has been called, and truly, "the General Practitioners' Bill." A few points were, of course, not *perfect*, but, on the whole, the Bill was a miracle of goodness compared to anything previously proposed, or even expected. The Committee gave it, as they ought, a warm support, and this generally was reciprocated throughout the country. "At the same time," the Committee remark,

"At the same time some of their professional brethren were misled into a factious and dangerous opposition, *by sophistical reasonings* and *wilful* misrepresentations, a circumstance which the Committee had much cause to regret, as at that time they had reason to believe that an arrangement in accordance with a compact entered into by each of the three bodies with the Government was on the point of completion.

"However this might be, the Colleges of Physicians and Surgeons not only regarded the scheme with jealousy, but respectively, after the lapse of a considerable period, published statements opposed to it, and ultimately determined to resist it, unless materially modified.

"Thus the only effectual opposition to the amended bill of May the 7th, came from the Colleges of Physicians and Surgeons. It was in fact opposed on the principle of being a general practitioner's bill."

In the new negotiations, thus unfortunately necessitated, the deputation acting for the Association felt compelled, as the less evil, to concede the three points insisted on by their opponents, and spoken of in the report we last week mentioned. They were, however, to be indemnified by, among other things, the concession to the Fellows of the New College of the title of Members of the College of Surgeons. A new point was now raised: the old colleges insisted on a second examination of the general practitioner by a conjoined board of their formation, as a mode of protecting their vested interests, rather than of throwing doubt on the competency of his examination by his own board. For various reasons (the principal of which is that the innovation gives the candidate a double *éclat*, and rather tends to *raise* than depress the qualifications of the class of general practitioners), the Committee did not feel it necessary to make this point a case for breaking up the negotiations. A concession was involved it; but it was equally a concession of the physicians who gave up medicine, of the surgeons who gave up surgery, as well as of the general practitioners who abandoned the exclusive right to a qualifying examination.

The Committee establish the enormous difference between the New College as proposed and the Society of Apothecaries:

"The physicians have at various times been understood to hold that it was the practising—not of physic—nor of medicine—but 'as an apothecary' which led them to agree to the act of 1815.

"But it is the practising as an 'apothecary,' that the general practitioner of the present day repudiates, scarcely an individual adopts the title.

"In the next place, this act of Parliament has been extensively evaded, and it is not likely that the evasion for the future will be less frequent than heretofore.

"Under the plea of practising as *pure surgeons*, gentlemen have considered themselves qualified for the general practice of medicine, surgery, and midwifery, with a diploma from the College of Surgeons only, that diploma having been obtained by a lax and incomplete examination constituting a test, as confessed by the Council, and as in reality it was, 'of that amount of information and skill which is absolutely required for the ordinary exigencies of surgical ministrations' only.—*Letter from the College of Surgeons, Transactions, April 7th.*

"Gentlemen for years past have been advised on high authority—*and have been encouraged by the example of the members of the Council of the College*—to enter into practice on this one test of qualification; the plea being, that they should practice as *pure surgeons*. The more respectable individuals acting under this advice have made no show of business, and even though practising as general practitioners, and frequently dispensing their own medicines, have done so in the outward character of pure surgeons, thus evading the apothecaries' act.

"But this was only a minor part of the evil. If one class of individuals, acting under the advice of the influential members of the College, were allowed to evade the law with impunity, another class could not be very easily punished who evaded the law of their own accord; hence arose the class of surgeons practising as apothecaries upon inadequate qualifications; 'retail shopkeepers,' who 'exposed for sale cattle drugs and perfumery,' 'puffers and vendors of nostrums and secret remedies, and writers of indecent advertisements, ill sustaining a professional character,' yet 'not chargeable with any moral disqualification,' persons of 'notoriously bad character,' and 'those who have violated the laws of their country.'—*Lit. Cit.*

"The apothecaries' act can rarely touch either of these classes, and it will be most especially noted that the College of Surgeons has no power whatever to enforce an examination in surgery—that they have no power to prosecute individuals for practising surgery without a diploma,—and, in fact, that any unqualified person whatever may practise surgery in this country in defiance of the College.

"But the general practitioners will gain, by giving up the power of licensing possessed by the Apothecaries' Society, the advantage of the whole arrangement of an incorporation of general practitioners, and especially the right of examining in *surgery*, and the consequent power of enforcing an efficient *surgical* as well as medical qualification.

"Much evil has arisen from the distaste of the general practitioner to the title of apothecary, coupled with the defects of the act of 1815, which enabled the society to authorise individuals to practise medicine 'as apothecaries' only, and the facts themselves are calculated to show the real nature, tendency, and value of the power of licensing possessed by the Apothecaries' Society.

* * * * * * * *

"The question with the Committee has been, would this compromise tend to secure to the general practitioners in medicine, surgery, and midwifery the rights, privileges, and position to which they are so justly entitled? Would it secure to them the fulfilment of those legitimate objects for which they have so long contended, and for which the National Association was called into existence? After the most mature deliberation, the Committee unhesitatingly say—if carried out *bonâ fide* upon the principles detailed to them by the joint deputation—it certainly would tend to do so."

The Committee are quite right in viewing the arrangement as a treble compromise — a compromise, without agreeing to which they must make up their minds to abandon the hope of a Government measure, unless one passed in their own despite. The important point is to see that, after having conceded to the utmost point by their deputation, further concessions be not enacted for them in the bill itself. The bill, we need not say, does some things the deputation were promised should not be done, and does not do other things which they were promised should be done. The Committee, aware of this fact, treat the compromise made by the deputation as the "utmost verge of concession," and will recognise with support no bill that will go one inch further. But this is said *en passant*.

The Committee then proceed to consider how far the present arrangement carries out the original intentions of the Association. They show that the

terms agreed to by *the deputation*, gave a new incorporation of General Practitioners with the full power of electing their own officers, forming their own court of examiners, fixing their own curriculum of study, testing to the full their candidate's competency in all branches of his profession: they also extend the title Surgeon to every member, allow him, after twelve years' practice, to become a Fellow of the College of Surgeons without further compulsory education, or at 40, in the same way, to become a member of the College of Physicians; they repeal the Apothecaries' Act of 1815, while giving much better guarantees for the suppression of quackery; they place the General Practitioner on the same footing with Physicians and pure Surgeons as to places in the Council of Health; they deprive the Council of Health of the power of excluding General Practitioners from high medical and surgical posts of public distinction; they raise the age for practice from 21 to 22; and exclude the insidious and mischievous distinction in favour of inceptor-candidates; they, in fine, tend, as a whole, to do what the Association has always struggled for—"to elevate the character and to increase the usefulness of all medical practitioners alike."—*Committee's Report, March 20.*

The Committee conclude an address which proves alike the zealous industry, and circumspect and thoughtful sagacity which they have devoted to their voluntary labour of professional well-doing in the following words, which deserve, on many accounts, to be commended to the careful consideration of our readers. The distinct but dignified enunciation of their readiness to take up the subject of A VOLUNTARY FACULTY OF MEDICINE, if circumstances offer them no other honourable solution of the great problem they are pledged at all sacrifices to solve, ought to make a deep impression on the mind of the whole profession:

"The Committee of the National Association accordingly urge upon the members the patient, deliberate, and unprejudiced consideration of the new bill, and they hope, during the present recess, to collect the opinions, and to receive the advice, of the various functionaries over the country, and of every individual member of the Association who can sacrifice that time and attention which such a complicated subject demands in order to give value to any opinion. In this address, the Committee have touched little upon any matter which relates to other than their own class in the profession, and not at all upon the various questions which bear upon the Scotch and Irish colleges, and different interests which have presented themselves for consideration during the negotiations. Yet each of these has to be considered in relation to the whole question.

"The Committee most emphatically direct the attention of their professional brethren to the facts, that, in legislating for the medical profession, the parties who have undertaken the duty have not a new subject to deal with; that the task would be comparatively easy if such were the case; that in *repealing laws*, and altering charters which have been in force for centuries, as also in enacting a *new law*, the numerous existing interests, corporate and otherwise, use their most persevering efforts to enforce their claims upon the government and the legislature. It must, therefore, be evident that these conflicting claims constitute the main difficulties of this complicated question.

"The Committee now further beg to recal the attention of the members to the report adopted at the public meeting held at the Hanover Square Rooms, on Tuesday, May the 6th, and published in the Transactions bearing date May the 9th. By that report, and other proceedings, it will be perceived that the National Association is by no means averse to a change being effected in the constitution of the College of Surgeons. It is there distinctly stated that if the efforts in that direction were successful, 'A NEW INCORPORATION would be unnecessary.' To assert that to open the College of Surgeons would be 'unpalatable' to the Association, is untrue.

"The Committee believe now, as then, that the attempt to do so will prove futile, and that the object is purposely set up, like an *ignis fatuus*, to misguide the general practitioners of the country, and to break up their organisation. The College of Surgeons, from an early period, have contemplated applying for a supplemental charter, to enable them to confer their fellowship upon a few individuals who have been members for twenty years, under *restrictions*, and upon *testimonials*. But will this satisfy the surgeons of this country?—those who, by their resolutions at public meetings, have declared that 'the general practitioners ought to be invested with the power of electing the Council, and are entitled to seats at the Council,' and who, by their memorials, have also declared that 'all those who were admitted members previous to September, 1843, should, upon just and equitable principles, be placed upon an equality with the recently elected fellows?'

"That the College of Surgeons can ever become the representative institution which the general practitioners require is not at all probable. It will never be allowed to be so changed as to become an examining body to certify in physic. To give the franchise to the members at large would lead to this result. The College of Surgeons has also, under the recent charter, taken money from members of very many years' standing, after first subjecting them to examination for the fellowship. How, after this, in common justice, can they create the remaining members, or any considerable portion of them, into fellows, without examination? If the claims of all the existing members were satisfied, would the surgeons of this country accept that boon at the expense of making all future surgeons, except a few who acquire the fellowship at twenty-six years of age, *a class of inferior surgeons?*

"The Committee again repeat, that in the best judgment they can bring to bear upon the subject, if the proposed arrangement be carried out *bonâ fide* the measure is a good one. All that is good in the representative principle will be obtained for the profession by giving the great body of highly-educated and fully-competent general practitioners in this country a liberal representative institution. The materials for scientific discovery and improvement will for the future be most effectually worked, and the ability and energies of the workmen augmented a hundred-fold. But the arrangement must be carried out in good faith,—that is to say, the new College must not be subject to have its power of regulating the curriculum of education and of testing by examination the qualifications of its future members, curtailed or restricted by any superior power—much less by any party who might have an interest, corporate or otherwise, in maintaining a low standard of qualification for the general practitioners of this country. This appears to have been guarded against, by the promise of the minister, to insert a clause in the bill, to the effect, that the power of the Council of Health to change the curriculum or to interfere with the examinations shall be exercised for the purpose of *extending* but not of *limiting* the nature and extent of the student's education and examination, as determined and carried into effect by the New College. The New College must also possess an income that will enable it efficiently to fulfil its important public and corporate functions; and the Committee are most happy to inform the members, that the proposed fee for the diploma, which, in the opinion of the Committee, will secure an adequate fund, has not been objected to by the government.

"The Committee feel, on the one hand, that if all parties unite their efforts to give efficiency and stability to a new Royal College of General Practitioners, with a view to elevate the character of the profession, upholding the attainments, the honour, and the station of the class for which it is provided; and in the proposed arrangements securing and sustaining the pre-eminence of the Colleges of Physicians and Surgeons among the Medical Institutions of Europe; the peace of the profession will be re-established, and a great blessing will be conferred on the population of this country. The Apothecaries' Society has, in the most disinterested manner, testified its readiness to make the greatest concessions for the interest of the general practitioners. The National Association has also shown every disposition to concede conventionalities for the sake of the SUBSTANCE—which, seeing the justice of the claim, was distinctly promised them by the Right Hon. the Home Secretary.

"If, on the other hand, opposing parties unite their efforts and employ the facilities of communicating with the government which they enjoy, and the influence they possess with the government, for the purpose of inducing it to curtail the powers and privileges of the proposed new Royal College, and in the spirit of corporate jealousy, without regard to the true interests of the profession and of the public, to impair its utility, efficiency, and respectability, if they defeat every effort to amalgamate the profession except upon terms so degrading as to render them impossible to be acceded to, *then will it become the duty of the National Association to extend the sphere of its operations—to compose anew the whole question of medical reform, and to* STAND BOLDLY FORWARD, ON THE BROAD PRINCIPLE OF THE PUBLIC GOOD, AS THE OPPONENT OF THE EXISTING INSTITUTIONS. The Committee would regard the conflict which this must lead to, as greatly to be deplored. They are aware that it might be of years' duration, and none know better than themselves the personal sacrifices which must be made. But they have such confidence, engendered by the events of the year last past, in the public spirit of the medical profession, as to feel the most perfect assurance, that so soon as a deep sense of imperative duty becomes the impelling agent, their professional brethren will act as one harmonious whole; AND EMPLOY THEIR UNITED EXERTIONS, WITH THE MOST ENDURING PERSEVERANCE, TO OBTAIN A FACULTY OF MEDICINE; without regard to the interests of those colleges, which by the aid of corporate privileges, conferred upon them in the comparative infancy of man's civilisation, have opposed themselves to the changes and ameliorations, which become essentially necessary as time wears on; and have thus by retarding the progress of the healing art, and preventing the diffusion of scientific knowledge among its professors, shown themselves totally regardless of the miseries and mortality of their fellow-creatures."

LORD ASHLEY'S LUNACY BILL.

The "Act for the regulation of the care and treatment of Lunatics" is now before us. We will briefly abstract what is of interest to the profession. Clause 1 respects several statutes; 2 names the commissioners "the masters in lunacy;" 14 limits the jurisdiction for granting licences to London, and about seven miles round; 17, the justices elsewhere license, and are to name a committee, consisting of justices and one or two medical men, to examine and inspect asylums. These medical men cannot sign certificates for the admission of patients, or attend them in asylums under a penalty. 29, applicants for licenses must state the nature and class of their patients; 41, justices can revoke licenses. 43 thus enacts:—

"And be it enacted, that the regulations as to lunatics of every hospital in which lunatics are or shall be received shall be printed, and complete copies thereof shall be sent to the commissioners, and also kept hung up in the visitors' room of such hospital; and that every such hospital shall have a physician, surgeon, or apothecary resident therein, as the superintendent and medical attendant thereof; and such superintendent shall immediately after the passing of this act (or immediately after the establishment of such hospital, as the case may be,) apply to the commissioners to have such hospital registered, and thereupon such hospital shall be registered in a book to be kept for that purpose by the commissioners; and in case the superintendent of any such hospital shall at any time omit to have copies of such regulations sent or hung up as aforesaid, or to apply to have such hospital registered as aforesaid, he shall for every such omission forfeit a sum not exceeding twenty pounds."

By the next clause a license must be obtained where there is more than one patient; and (45)

none must be admitted without a certificate from two medical men, and their certificate (46) must contain the specific grounds of their belief. Interested medical men (belonging to asylums, &c.) must not sign the certificate. The admission, escape, death, discharge, removal, &c. of a patient, must be noticed to the commissioners. Abuse, neglect, or ill-treatment of the insane is made a misdemeanor. Houses with a hundred patients must have a *resident* medical attendant; with less, a medical attendant attending twice a week. A weekly registry of the cases and the condition is to be kept in each asylum, with a "medical case-book." Asylums are to be visited four times a year by commissioners, or the "visitors," and there must be no concealment by the proprietor under a misdemeanor. Provisions are made for the commissioner seeing the register books, &c., for a copy of the act being in every asylum, for a patient's book being kept for registering visitor's observations. Asylums may be visited at night, if the visitors or commissioners wish; commissioners are given the power of discharging patients. Clause 90 is important:—

"And be it enacted, that no person (unless he be a person who derives no profit from the charge, or a committee appointed by the Lord Chancellor) shall receive to board or lodge in any house, other than a hospital registered under this act, or an asylum, or a house licensed under this act, or under one of the acts hereinbefore repealed, or take the care or charge of any one patient as a lunatic or alleged lunatic, without the like order and medical certificates in respect of such patient as are hereinbefore required on the reception of a patient (not being a pauper) into a licensed house; and that every person (except a person deriving no profit from the charge, or a committee appointed by the Lord Chancellor,) who shall receive to board or lodge in any unlicensed house, not being a registered hospital or an asylum, or take the care or charge of any one patient as a lunatic or alleged lunatic, shall, within seven clear days after so receiving or taking such patient, transmit to the secretary of the commissioners a true and perfect copy of the order and medical certificates on which such patient has been so received, and a statement of the date of such reception, and of the situation of the house into which such patient has been received, and of the christian and surname and occupation of the occupier thereof, and of the person by whom the care and charge of such patient has been taken; and every such patient shall at least once in every two weeks be visited by a physician, surgeon, or apothecary not deriving, and not having a partner, father, son, or brother who derives, any profit from the care or charge of such patient; and such physician, surgeon, or apothecary shall enter in a book, to be kept at the house or hospital for that purpose, to be called 'the medical visitation book,' the date of each of his visits, and a statement of the condition of the patient's health, both mental and bodily, and of the condition of the house in which such patient is, and such book shall be produced to the visiting commissioner on every visit, and shall be signed by him as having been so produced; and the person by whom the care or charge of such patient has been taken, or into whose house he has been received as aforesaid, shall transmit to the secretary of the commissioners the same notices and statements of the death, removal, escape, and re-capture of such lunatic, and within the same periods, as are hereinbefore required in the case of the death, removal, escape, and re-capture of a patient (not being a pauper) received into a licensed house; and that every person who shall receive into an unlicensed house, not being a registered hospital nor an asylum, or take the care or charge of any person therein as a lunatic, without first having such order or medical certificates as aforesaid, or who, having received any such patient, shall not within the several periods aforesaid transmit to the secretary of the commissioners such copy, statement, and notices as aforesaid, or shall fail to cause such patient to be so visited by a medical attendant as aforesaid, and every such medical attendant who shall make an untrue entry in the said medical visitation book, shall be guilty of a misdemeanor."

Persons charged with a single patient are placed under the control of the commissioners, who may discharge the patient, &c.

THE UNIVERSITY OF EDINBURGH AS A MEDICAL SCHOOL IN 1845.

[Dr. Lewins has, with his paper, favoured us with the following letter.]

(Continued from page 380.)

Reference shall be made in a future article to the animadversions of O. P. Q. on the professors and patrons of the University of Edinburgh, published in *last* week's number of the *Medical Times* (August 2). At present, mine be the task to refute his erroneous conclusions, as recorded in that of July 19.

With such an intention, I resume consideration of the merits of the Edinburgh medical professors—and of the circumstances connected with their appointment as such; Monro, Graham, Alison, Christison, and Ballingall, have already been noticed, and the grounds stated, upon which *they* were selected by the patrons to fill their respective chairs. Dr. Traill's *appointment* has also been adverted to. Now, I proceed to speak of the claims *he* had to the honour of a professorship—claims which have been contemptuously questioned by O. P. Q.

When the chair of medical jurisprudence became vacant, in 1832, Dr. Traill was practising medicine, at Liverpool, O. P. Q. insinuates as a general practitioner; if Dr. Traill did so, does O. P. Q. imagine that that disqualified him from aspiring to the most responsible medical appointment a member of our profession can hold? O. P. Q., evidently a man of talent and learning, must be aware that (to say nothing of the ancients,) Hildanus, Severinus, Bartholine, and many others of distinguished genius, amongst the moderns, practised medicine and surgery, promiscuously, with splendid success; as did Cullen, the Hunters, Thomson, Abercrombie, and many celebrated men, besides. It is a fact, which it concerns the patrons of medical chairs to bear in mind—and which I would have O. P. Q. remember—that he who has been a successful general practitioner, and endowed with adequate literary and scientific knowledge, is, in reality, the member of our profession most worthy of preferment.

O. P. Q. is, it appears, profoundly learned in anatomy, human and comparative, without a competent knowledge of which no one, certainly, can be truly great, as a physician or as a surgeon; but, methinks, O. P. Q. attaches an undue degree of importance to anatomy; that is, with the natural partiality of a man for his own favourite study; and for a department of science, in which he feels himself strong, he over-estimates its value. Anatomy, however essential, never of itself yet made a first-rate physician or surgeon; and more than one of the most expert Scottish anatomists of the present day, (men most deservedly distinguished for knowledge of anatomy,) are, if the truth must be told, "pedagogues" of a most offensive description, and something that is worse. As to O. P. Q., in the spirit of the currier, in the besieged city, who declared that there is nothing like leather, the produce of his tan-pits, so the former seems to imagine, that the one thing needful to *all* medical professors, is insight gained amidst the filth and horrors of the dissecting room, with which he is, probably, very familiar, and may, thereby, have gained a notoriety that will transmit his name to posterity. Philosophers, however, are equally indifferent to the adulation and imprecations of the profane vulgar. To considerations so futile, O. P. Q. is, doubtless, ever ready to exclaim with Persius, "*Ad populum, phaleras, ego te* INTUS *et in* CUTE, *novi*." But to return to the immediate object of my undertaking. At Liverpool, in the active discharge of his professional duties, Dr. Traill continued to cultivate the habits of an enthusiastic student, and gave such ample proof of ardent devotion to the cause of science, as fully to justify the home secretary of the day in nominating him to a chair in one of our most celebrated medical schools: a nomination which, in opposition to the sarcastic sneers of O. P. Q., I maintain did no discredit to the university of the Monros *primus et secundus*, and to that of the Gregorys, and of Cullen, of Black, of Duncan, of Hamilton, and of Bell.

Dr. Traill has proved himself a good and an acceptable teacher of medical jurisprudence. As a professor of clinical medicine, he is beloved by the patients in the Royal Infirmary, and respected by the students of the medical school, of Edinburgh.

Few members of our profession have written (and written well) on a greater variety of subjects than Dr. Traill. It is, perhaps, true that, had his efforts been more concentrated, he might have accomplished his work still better; but, be that as it may, the fact remains unquestionable, that the present professor of medical jurisprudence at Edinburgh, has acquitted himself well—that he has been, and continues to be, a zealous cultivator of science—and that he is a good specimen of a teacher, who has the peculiar gift of inducing his pupils to follow his meritorious example—a gift, when possessed by a professor, of inestimable value to the students, and highly conducive to their future progress in the right direction.

O. P. Q. admits that Dr. Traill is "a good-natured man, and a kind-hearted gentleman." His good nature, and the kindliness of his heart, are in no way more nobly manifested, than in the delight he experiences in imbuing his pupils with a passion for science, and in the prospect of his precepts and example being the means of making some of them, at least, one day equalling, or surpassing himself in the cultivation thereof. The constitution of mind that engenders such a feeling is widely different, indeed, from that of a pedagogue's, and evidences true magnanimity, without which no man can efficiently fill an academical chair, or any other responsible situation;—an honourable achievement, which, I repeat, has been accomplished by Dr. Traill, late medical practitioner at Liverpool.

According to the arrangement I proposed to adopt, in endeavouring to controvert the sentiments of O. P. Q., the chair of clinical surgery is the next which it is incumbent on me to notice. Too true it is that, as has been said by O. P. Q., in reference to the appointment of professors in general, there were circumstances connected with the nomination to the chair Mr. Syme occupies, calculated not only "to wither the young and ardent mind," but to annihilate the hopes, and to sicken the hearts, of some who had long laboured in the field of medical science. The late Mr. Russell, who had filled the chair of clinical surgery for thirty years, was allowed to dispose of it! He made it a matter of "attorneyship;" and, after much wretched intriguing, on his part at least, Mr. Syme paid the price demanded! report said, an exorbitant one. Such was the inglorious manner he got possession of his chair. The transaction referred to was, doubtless, a very disreputable one, and discreditable to all concerned, but especially to the late professor and to those who dispensed the crown patronage in Scotland at the period to which I allude (1833). The plain and unvarnished state of the case is this: a rich old man (an octogenarian, or nearly so), in whom the maxims of philosophy did not moderate an insatiable desire of additional wealth, was permitted, if not coaxed, to make merchandize of a medical chair in the gift of the crown! He virtually "put it up" for sale, and "knocked it down" to the highest bidder. And to that disgraceful transaction those who were delegated with the honourable trust of filling the *regius chairs* in the Scotch universities were parties[1]—parties that cruelly disappointed the cherished hopes of at least one admirably qualified aspirant to the chair in question. Alas!

"Slow rises worth by poverty depress'd."

It is true that all who are qualified cannot be installed as professors, nor occupy the principal places in our colleges and higher schools of instruc-

---

[1] It is no satisfactory refutation of this serious charge, to say that the government agent in Scotland was satisfied that the talents of Mr. Syme entitled him to the honourable place he longed to fill. Allowing the fact to be so, it exonerates neither the minister nor his man who negotiated "the *business*" from the implication of having acted a part that, whilst it did an injustice to the profession, compromised the dignity of the crown.

tion; but when a vacancy occurs, every worthy individual should be allowed to enter the field of competition, undeterred by the exactions of a rapacious predecessor, aided and abetted by the unscrupulous agents of a minister of "easy virtue." The act deprecated, in regard to the appointment of a professor to the chair of clinical surgery in the university of Edinburgh, I say again was a disgraceful one, and its consummation a reproach to those who were entrusted with the responsible duty of superintending the appointment of professors to regius chairs. There is, however, good reason to suppose that it will be long ere such chicanery be again practised in the disposal of a professorship at Edinburgh or elsewhere in the Queen of England's dominions.

This is not the place to speak of the merits or demerits of our political rulers—a subject on which I am little accustomed to descant—but upon this occasion I may be allowed to say, in reference to appointments made to offices held by literary and scientific men, that the conduct of the present Prime Minister of the British empire, and that of the Secretary of State for the Home Department, affords a striking and triumphant contrast to the doings of their predecessors, in whose eyes political partisanship was much too often considered a matter of more importance than personal worth, scientific attainments, or literary acquirements. Upon this subject—one to which it is good to direct the attention of the medical public on proper occasions—I shall perhaps say more at another time, in reverting to certain fantastic tricks played, some fourteen years ago and since, in regard to the creation of medical chairs and to the appointment of professors in Scotch universities.

Censurable as was the mode in which Mr. Syme entered the portals of the university as a professor, no one can deny that his talents have enabled him creditably to support the position he occupies within its walls. His perfect knowledge of the principles of surgery render his lectures interesting and instructive. Under his superintendence the clinical wards of the Royal Infirmary have afforded wider scope and additional facilities than previously existed for the acquisition of surgical knowledge in an hospital which has long most deservedly been held in high estimation for the excellence of its system of clinical instruction, medical and surgical. The medical school of the University of Edinburgh was not only the first, but for a long time the *only*, one in which the principles and practice of surgery were taught by clinical lectures.

Mr. Syme shows no inordinate love of "cutting." He is not a dashing operator, but as an operator true as the steel he handles, and rarely fails in accomplishing the object he contemplates. His after-treatment invariably displays the knowledge of one well acquainted with the philosophy of physic. His clinical discourses are, therefore, highly interesting, as was said before, and replete with sound instruction.

As an author, the Edinburgh Professor of Clinical Surgery is not only favourably known, but, with truth and justice it may be said, his writings are not inferior in value to those of the first surgeons of the present day. Mr. Syme's earlier efforts in the cause of surgical science, published some twenty years ago, entitled "Anatomical Remarks on the Fasciæ of the Groin," and his "Observations on the Treatment of Incised Wounds," afforded conclusive evidence of his being possessed of qualifications essential to the constitution of an accomplished surgeon, and gave ample promise of future chirurgical celebrity. In support of his claims to such honourable distinction, I would particularly refer to a report, published by him in the *Edinburgh Medical and Surgical Journal*, of a case of amputation at the hip-joint, and to his "Remarks on Amputation," written with the intention of showing that the flap-operation is preferable to the circular method, which was practised at the period alluded to by all the first surgeons in Europe, with the exception of Mr. Liston, who had for several years previously completely abandoned the operation by the circular incision[2]—an operation which, to my astonishment, I find is still performed in some parts of England. I would earnestly direct the attention of those who persist in amputating limbs in the method recommended by the surgeons of the last century to the following graphic statement of the result of the two operations:—

"It is impossible to imagine a greater contrast than that afforded by a comparison between the wound which results from this operation, and that caused by the method of circular incisions. The bone, instead of standing naked and conspicuous, can hardly be discovered until the flaps are laid aside. The muscles, not now deeply retracted, and exposing an abrupt, ragged termination, extend far beyond the bone, and display two smooth equal surfaces, amply sufficient for coming into mutual contact, and well disposed for reciprocal union. Lastly, the skin, so far from forming a loose and hanging border about the wound, is left in undisturbed connection with the subjacent parts, and in proportion just sufficient for supporting and covering them when the two flaps are brought together. The difference of appearance is not less remarkable after the wounds have been dressed.

"In the one case the line of union is straight, in the other it represents the arc of a circle; in the first there is puckering of the integuments, in the second there is none; in the former, the muscles form projecting and inconvenient corners; in the latter, they exist only where they are most required, i. e., over the bone. Union by the first intention most commonly attends amputation by flaps; but, if suppuration does become established, there is much less inconvenience than generally happens, and I may here remark, that many as the operations which I have seen of this kind are, I never yet met with an instance of the bone protruding or exfoliating. I may notice, too, that the inconvenience mentioned by Richter as the greatest attending the amputation of the thigh, viz., the extensive and long-continued retraction of the posterior muscles, is avoided, as those only on the lateral aspect are employed to cover the bone.

"The difference of comfort enjoyed by the patient after the cure is also most decidedly in favour of the flap method, since the stumps formed by it, instead of being conical and skinny, are uniformly round and fleshy."

Mr. Syme published an essay on the excision of the heads of bones; he also recommended and practised the excision of joints—a practice which, as demonstrated by experience, is an important improvement in modern surgery.[3] His "Principles of Surgery" is an excellent work, calculated to give young practitioners sound notions of the maladies with which they have to contend, and the means by which they must endeavour to counteract their effects.

Mr. Syme is also the author of a work on the "Diseases of the Rectum," which, I believe, is considered a valuable contribution to surgical science, and he read papers before the Royal Society, on the Formation of Bone, which are characteristic of a philosophic mind.

From the above brief reference to Professor Syme's works, I am entitled to affirm that, when weighed in O. P. Q.'s own balance (the value of an author's publications), he has not been found wanting, whilst it has besides been shown, by his *deeds*, that the Professor of Clinical Surgery in the University of Edinburgh has proved himself an efficient occupant of the chair, and that the character of his lectures authorises me to report him as a teacher of the highest order.

Tiverton, August 13, 1845.

(To be continued.)

[2] To Mr. Liston is due the honour of first inculcating by his precepts, and establishing by his practice, the superiority of the flap-operation over that of the circular incision in performing amputation, and of greatly simplifying the operation in other respects.

[3] The late Mr. Park, of Liverpool, had suggested a practice of the same kind, but it was adopted by few, if any, until recommended and practised by Mr. Syme.

(To the Editor of the Medical Times.)

SIR,—Herewith you will receive my third paper on the University of Edinburgh as a Medical School in 1845.

I have read with pleasure the courteous communication of your Manchester correspondent, A.W.C., on the subject—a communication written in the true spirit of an English gentleman. I cordially concur in his feelings and sentiments; and as a "combatant" fighting in defence of my honoured *Alma Mater*, feel proud of doing so under the eye of such a "spectator." Would to God that all members of our profession were influenced by such principles as those inculcated by A. W. C.! With him I say, success to him who holds the right in reference to the "tournament" now being fought for the fair fame of a lady of great wisdom (to which the University of Edinburgh was likened by my late friend, Dr. Mackintosh), and I may add, of royal origin, "comely to look at, who had nourished and brought up a numerous family, now dispersed in all corners of the world, distinguishing themselves honourably, and spreading the name of their foster-mother over all the habitable earth." And I would, *en passant*, remark, that Dr. Mackintosh was little disposed to allow any merit to the university of the northern metropolis to which it is not strictly entitled. Truth is my object in the present controversy; with it and justice, as I conceive, on my side, I entered the lists, confident of victory—continuing to fight under such banners, I as confidently hope to be crowned therewith ere I leave them. But, as I said before, my motto is, "Success to him who holds the right."

It gives additional interest to the contest, and increased animation to the combatants, that their deeds are faithfully reported in a medical periodical, now, certainly, in more extensive circulation than any in Europe. May its principles ever prove worthy of the powerful patronage it enjoys!

I am, &c.,

Tiverton. ROBERT LEWINS.

MEDICINE IN WORKHOUSES.

(To the Editor of the Medical Times.)

SIR,—On March 5, 1844, Lord Ashley rose in his place in Parliament, and said, "The House was spared the infliction of a long and painful statement, by the assent of her Majesty's government to the proposition of which he had given notice—'That a select committee be appointed to inquire into the mode of administering relief to the sick poor, under the provisions of the Poor Law Amendment Act, and to report the evidence taken before them, with their opinion, to the House.'"

This committee sat day after day, summoning witnesses from all parts of England, and eliciting facts, the recital of which would be, no doubt, "*long and painful.*" The session ended—the committee broke up: we have seen another session begin and pass away, but we have not yet received a report, either long or painful. His lordship (I have it on authority) *did* elicit sufficient evidence to prove that the present system of medical relief is, in every respect, deficient—the suffering poor not sufficiently cared for—the medical officer in no case remunerated, in many cases not paid the bare cost of his medicines, exposed to the rudest attacks from guardians, and his reputation in many cases at the mercy of some hireling relieving officer, or some opposing and interested guardian. I write not hypothetically, I can prove all I hint at, and much more. I can prove, in some of the most dangerous and critical cases that afflict humanity—the fact stands recorded on the minutes of a board in this county—that a medical officer was harassed by a complaint of having ordered too much "*sick necessaries*" to a supposed dying pauper; the complaint was made by a jealous and officious guardian, who called to his aid the relieving officer. They stated their complaint, and they were replied to; and, to the credit of the board, a minute was entered of their entire concurrence in the act of their medical officer. But such things should not be; they ought not to be able to occur; a public officer, having the care of the sick, should never have the dread of a jealous guardian before his eyes. I have known a case—nay, I have it in my own keeping—where an influential guardian has got a dozen farmers to pass a vote of censure on a surgeon, and merely to gratify private animosity. I had made myself conversant with those cases, with a view of laying them all before Lord Ashley's committee;

but private circumstances of an important nature prevented my being in town.

The commissioners' orders, even for the payment of certain extra fees to medical officers, are in many of the unions evaded: the commissioners know it, and yet they do not enforce their own order. When will the system be made better? When shall we reap the fruits of the late investigation? This is a question of more importance than the "Physic and Surgery Bill." It affects the profession as a body; and it affects more than five millions of our fellow-subjects, the recipients of parish, or, rather, union medical relief. You have of late dropped the subject. Again lend your strong right hand to it; assist the cause, not only of the profession, but be a friend to the friendless sick pauper.

Yours, &c.,
A Subscriber.

Exeter, August 11, 1845.

PROVINCIAL MEDICAL ASSOCIATION.

"L'union fait la force."

(To the Editor of the Medical Times.)

Sir,—I think very highly of your valuable journal, and particularly of the respectability which characterises its management; but, thinking you have handled the Provincial Medical and Surgical Association rather too roughly, I venture to offer a few observations upon your leading article of the 9th August.

The object of that article appears to be to throw discredit upon the proceedings of the Association, principally because it has not taken a very prominent part in the exciting subject of medical reform; but before this charge can be fairly laid, the objects for which the society was established should be fully borne in mind. The annual volume of Transactions proves the great extent to which those objects have been attained; the retrospective addresses, the original essays, the topographical papers, and the reports of various diseases, both in public and private practice, afford a fund of information, practical and speculative, which will bear comparison with that contained in almost any other publication in the kingdom of the same dimensions: and when it is considered that this amount of information is placed in the hands of every member of this large Association, it will be difficult to estimate the value, or limit the benefit, conferred by the Association upon the profession and the public. The weekly journal also, according to your own admission, "may excite, but cannot satisfy a taste for journalism." May it not also excite a taste for professional study, and, by encouraging these tastes in a large number of medical men, become the indirect means of increasing and widely disseminating more real professional knowledge? I am willing to allow, however, that these advantages to be derived from the Journal might perhaps be equally well secured by one of half the size; and the reduction of expense would afford the society the means of extending still further its usefulness.

Your principal ground of complaint against the Association is its inefficiency as a political engine; but such exercise of its powers appears not to have been contemplated by its founders, and, therefore, on that score it ought to be exempt from reproach. Yet I think that a calm and dispassionate review of the past proceedings of the Association, even in a political point of view, will prove that it has been watchful over the interests of the profession; and not only so, but that it has actually effected some good. I allude more particularly to the influence exerted by its poor-law committee, in bringing about certain modifications and improvements in the laws relating to poor-law medical relief; and by its medical reform committee, in adding force to the suggestions and recommendations of other bodies with reference to various clauses in Sir James Graham's medical bill. It is true that what the Association has accomplished in these matters has been done quietly, by the force of moral principle and persuasion, and not ostentatiously, by fierce declamation and bitter invective. The latter weapons have so often been wielded by certain "medical reformers," with little effect beyond that of bringing contempt and degradation upon those who used them, that it would indeed be absurd for a body of gentlemen, devoted to their profession and esteemed for their conduct, to follow a course so derogatory and ineffectual. With reference to the inactivity of the reform committee at the late meeting at Sheffield, was it not a wise proceeding to keep the subject, as it were, in abeyance until the new bill was printed? Until that bill is before the profession, I cannot imagine that any public discussion can be productive of advancement in the cause of medical reform. The committee will, no doubt, be upon the alert; and should the thrice amended bill contain any provision that may seriously demand the active interference of the Provincial Association, I doubt not but it possesses both the power and the will to make known the wishes, and probably to secure the just demands, of the great body of provincial practitioners.

You also remark, with no small degree of sarcasm, upon the social part of the proceedings at Sheffield, and observe that "the meeting seemed like the anniversary of a society founded for the promotion of mutual admiration." Now, if I may form a right estimate of your principles and feelings by the general tone of the journal you so ably conduct, I should unhesitatingly say that you were not the person from whom I should expect such an observation. "Maintenance of the honour and respectability of the profession, by promoting friendly intercourse and free communication of its members," &c., is one of the stated objects of the society; and can anything tend more to the elevation of our profession than encouraging a high standard of professional morals and gentlemanly bearing amongst its members? Can any legal or parliamentary interference effect so beneficial a reform as we could ourselves obtain by striving, individually and collectively, to attain to perfection of conduct? Surely one great means of accomplishing this great object is to join in social intercourse, even at yearly intervals, with those whose minds are of the highest order—whose attainments, educational and professional, are equal to any in the land—whose moral worth is beyond reproach—and whose gentlemanly demeanour renders them objects of esteem and respect. To such men, and there are many, compliments are neither needless nor injudicious expressions of feeling, but rather incentives to greater and more strenuous exertions to deserve them. I have endeavoured to show that the objects for which the Provincial Association was founded have been usefully carried out; that the society is by no means indifferent to the wants and wishes of the profession; that it is capable of doing much good, and willing to exert its powers when fitting occasions for its interference present themselves. Let me persuade you, then, to lend your powerful aid to insure its full amount of influence for good, and no more to chastise it for not accomplishing all that you and others can view in prospective as desirable acquisitions to the medical profession.

I have the honour to be, Sir,
Your obedient servant,
A Constant Reader.

Norfolk, August, 1845.

MISCELLANEOUS CORRESPONDENCE.

Liebig and his Chemistry.—When Liebig's works were first published, the enthusiasm with which they were received induced me to study them carefully, and I must confess that I laid them down without that veneration for the author which is felt by almost every chemist. While, however, Liebig's authority was conclusive among chemists only, the matter was not of much consequence, but having observed a work advertised in which it is proposed to treat disease on Liebig's principles, I think it right to call the attention of your readers to two points discussed within a few pages of his "Familiar Letters," second edition. At p. 63 we read, "the size of the thorax of an animal is unchangeable; we may, therefore, regard the volume of air which enters at every inspiration as uniform." Now, surely it requires no argument to show that the depth of each inspiration is a most variable thing. Were this a mere passing erroneous assertion, I should not notice it, as I have no wish to search for blots, and know the difficulty of attaining accuracy in all things; but this is an assertion which lies at the very foundation of one of his most celebrated theories, and which is assumed, without being asserted, in his larger work. His argument is as follows:—Warm air is lighter than cold air; consequently, in the summer less oxygen is inspired than in the winter. This, of course, takes for granted what ought, in truth, to be proved, namely, that the *frequency* and *depth* of inspiration always remains the same; and on this assumption is built the pathology and cure of phthisis, and other little et cæteras. At p. 88, after speaking of vegetable fibrine, albumen, and caseine, he says, that they are all "identical in composition with the chief constituents of the blood. * * * It is especially to be noticed, that by the phrase 'identity of composition' we do not here intend mere similarity, but even in regard to the presence and relative amount of sulphur, *phosphorus*, and *phosphate of lime*, no difference can be observed." Immediately after follows a theory commencing "How beautifully and admirably simple, with the aid of these discoveries," &c.; yet, on turning on to p. 94, we find him deep in another brilliant theory, and, in order to support it, saying, that "animal caseine, when chemically examined, is found to contain *a much larger* proportion of the earth of bones" (*phosphate of lime*) "than blood does," the absolute identity of animal and vegetable caseine having been asserted in p. 93. To give one other specimen of Liebig's acuteness in argument, I will just refer to one of the proofs on which he rests his assertion, that humus, or vegetable soil, is not necessary for the growth of plants. It is that the *first* trees must have existed without the aid of decayed vegetables; and this argument, founded solely on our ignorance of the state of things at the creation, has been looked upon as conclusive.—G. S., Bromley, Kent.

To the London College of Surgeons.—I have an attachment to the College of Surgeons, arising, perhaps, from an innate love of old institutions with which the names of celebrated men have been connected. I have felt disposed to fancy—for it *is* a simple idea of the imagination—that the genius which animated such men must have descended as a sort of heirloom to their successors; I have, therefore, hitherto refused to join the Association of General Practitioners. But my hesitation gives way; actions and facts press upon me; the men who would govern the College of Surgeons *will not* "devise liberal things"—will not think "whatsoever things are true, whatsoever things are honest, whatsoever things are just, whatsoever things are lovely, whatsoever things are of good report"—will not "put away childish things," but will "speak as children, understand as children, think as children." I will leave their society for that of men. I am about to join the Association, whose large and liberal views constrain me. Whilst I have been allured by the glory of great names, and have rejoiced in the collegiate ties which bound me to them, I have ever felt my pride to be humbled by the manifest and acknowledged insufficiency of the College examinations. As they would confine their honours to a circle of friends and associates, so do they limit their examinations to the circle of surgery and anatomy, as if they considered chemistry, materia medica, hygiene, and medical jurisprudence, irrelevant to the practice of the surgeon. My attention has been more particularly drawn to the subject by a fact recently brought under my notice. A druggist of this town offered himself to become a methodist preacher; he could not pass the usual theological initiatory examination, and was rejected. He then turned his attention to the medical profession. He studied at the medical school of this town; failed in the competition for prizes there given; was beaten by youths fifteen or twenty years his juniors, but *passed the College of Surgeons*. He is professedly afraid to present himself at Apothecaries' Hall. Yet here is one who, in the present anomalous state of the College and the profession, ranks nominally as the "pure surgeon,"—a man who feels himself to be unworthy of public confidence, but thrown upon the world by a college claiming exclusiveness, ascendency, privilege. Is the examination to be a test of competency? Then let such examinations be instituted as will embrace the subsidiary sciences. Let the so-called "heads of the profession" forsake the ignis fatuus of *pure surgery*; let them place themselves at the head of the Incorporation of Ge

neral Practitioners, and let that designation be transformed to that of surgeon, and they will surround themselves with a halo of glory, and their names will live in the memory and hearts of posterity. Why should it not be so? "Surgeons and physicians is the true classification of the medical profession." We are now living in the "era of nature," in which the various forms of intellect are developed and flourish; but that general mind is only about to disclose itself which will embrace, cherish, and re-unite all into one limitless and all-pervading spirit of intelligence. The struggle lies betwixt the intellect and the pocket—mind and matter—the love of principle, and the love of money. Let them yield to the supremacy of the former. Let them stoop to conquer. Let them yield to mind, to right, to conscience, and in so doing, honour, consultations, and wealth will follow.—M. R. C. S. E.

THE LONDON SURGICAL COUNCIL.—In the National Association of General Practitioners are nearly four thousand members of the College in arms against the Council of the College of Surgeons in England, and two-thirds at least of the members of the College are dissatisfied with the proceedings of the Council of that College. The Council in their statement (June 5) say, "That under hostile attacks, *devoid of any reasonable ground, and unsupported by any rational argument*, is the Royal College of Surgeons recently re-chartered by her Majesty for the promotion and cultivation of surgical science, *and not charged as unfaithful to*, or incapable of, its high functions. Thus is the Royal College of Surgeons of England in danger of being sacrificed to the views and wishes of those who hope to annihilate it by the establishment of a rival college of surgeons." If the above statement is correct, our opposition must have been marked with ignorance and folly. I say this for the following reasons:—Because the Council, at a time when it could have been effective in procuring a better education, and higher professional acquirements and *standing*, has not lifted a finger for that object. Because the charter of 1843 was carried out illiberally and unjustly. The Council state that the members are not degraded by that charter; that they have elevated the fellows but not depressed the members. Now, it will be granted that the *locus standi* of a member or fellow of any collegiate body is *relative*, not absolute; if so, to raise any member above another, is to place the one in a higher, and the other in a lower position, for there is thus positively and necessarily the comparative degree between them. Hence we, the body of members, say that we are degraded by this act of the Council. The title of member was the *highest known* to the College. By the working of the charter of 1843, *that highest title* is now become *the lowest*. Thus the statement of the Council in this point is not in accordance with fact. The members have requested the Council to cancel the inequality thus produced, but the Council have insolently refused this measure of justice to them, and in solemn conclave assert "*that they are not charged as unfaithful to*, or incapable of, the high functions for the promotion and cultivation of surgical science." Again, the Council is absolute and irresponsible. The Council, by its bye-laws, states that it will protect the members, but not one shilling has been paid for this purpose during the last half century. If a member wishes to have a list of the members of this College, he is allowed to possess it by paying for it. For such splendid immunities the members are bound to what they may not do by three or four pages of bye-laws. The Council, in swearing the members to observe the bye-laws, conduct that ceremony without those bye-laws being read or otherwise made known. The members are smuggled, as it were, into the taking of the oath, as though there were something about those bye-laws that cannot bear the daylight. Now, I object to paying my quotum of the £10,000 per annum in support of this institution which gives no protection, whose bye-laws for its members would be insulting, but for their puerilities, whose Council has impertinently refused any advances on the part of its members for a better understanding and organization of the profession, when Parliament was willing to act with it and take the initiative; a Council which affects to despise the members, and deny the right of self-government, which takes all opportunities of repudiating any connection with them. The Council, as some extenuation for this conduct, object that some members keep shops, &c., but let it be remembered the Council have themselves principally to blame for admitting such men, by their laxity of education and examination, and by providing the public with "*surgeons qualified for the ordinary exigencies of the profession only*." The College must be supported, and for this purpose our money is required, the country gets up a plentiful supply of surgeons, and hence many are dependent either on a shop or the charity of friends for a chief part of their living. The Council have sown the seeds of discord and discontent, and now expect to reap the fruits of wisdom and disinterestedness.—A GENERAL PRACTITIONER OF THE ASSOCIATION.

MEDICAL CLUBS AND CHARITIES.—The perusal of your observations on clubs induces me to call your most serious attention to an evil which, more than any other, appears to affect the present welfare and future prospects of the medical community. There is scarcely a town and village in the kingdom but teems with its friendly societies in some shape or other, male and female—societies useful if kept in their proper place, but at present inflicting most serious injury upon medical practitioners. These societies comprehend amongst their members people not only well to do in the world, but people of substance, whose sole aim is to cheat the doctor by procuring medicine and attendance at the lowest possible rate; and low enough it is in every sense of the word, the general sum of pay per head per annum varying from 1s. 6d. to 5s., generally standing at 2s. 6d., and yet for that pittance you find medical gentlemen (?) contending with one another, aye, canvassing the members, treating them, or offering the gratuitous bestowal of their valuable (?) services for a certain time, and this by men not dependent on their profession for subsistence; consequently, a well-principled, honourable man (I know of one instance at least), who will not pander to this degrading club-system, may be ruined in consequence of less scrupulous competitors creeping, cringing into the families attended by the former. The club-system is daily on the increase; those practitioners who are most averse to it are forced to succumb. At the same time, its very object is defeated, for those who are chosen by the clubs are generally ill-qualified, or neglect their patients. Sir, if you would perform the most eminent of services to the profession, take this subject in hand, and assist the respectable members of our body in throwing off this incubus. Invite communication and combination. Surely, the disease is not beyond remedy; surely, the united strength of the profession could bring to bear some means for checking those unworthy practitioners who help pharisaical directors to get a cheap repute for charity by robbing the doctors. From what I know, any movement originating in a powerful and influential organ, such as the *Medical Times*, would be well responded to on the part of the profession. Give us but a rallying point, and you will find the good cause attract the respectability and influence of the general practitioners.—A COUNTRY SURGEON.

PRACTICAL APPLICATION OF MESMERISM.—EXTRACTION OF A TOOTH WITHOUT PAIN.—SIR,—The following fact may prove of interest to some of your readers:—Attending a family at Clifton, I was asked to see a young woman who had been suffering from violent toothache, and had not resolution to have the tooth extracted in the natural state. On first trying to mesmerise her, an impression was made; my second trial convinced me that there was insensibility to pain; on my mesmerising her again on Saturday last, I found she was fully equal to any operation. I made an appointment with a dentist to meet me at 29, Park-street, at three o'clock. In less than ten minutes the patient, a timid and excitable young person, was sent into the mesmeric state. The tooth was a double one, with three fangs, and was firmly rooted in its socket; in truth, a powerful wrench was required to extract it. The gum was afterwards firmly pressed with the fingers. During this period the patient sat with her hands quietly resting on her lap; not the slightest motion of resistance could be detected by the lookers-on. After the operation, Mr. Mosely, the dentist, was asked his impression from what had passed. His reply was, "that there was perfect insensibility, and that she remained as passive as a block of wood." This opinion was the more satisfactory to me, Mr. Mosely being a perfect stranger, and having expressed himself as very doubtful whether mesmerism could be brought to such a practical bearing. On being awoke, the young woman looked about surprised at seeing strangers in the room, and when told that she would not now feel the tooth pain her, she doubtingly inquired, "What, then, is it out?" I need hardly say that such a result was as gratifying to those who witnessed the operation, as to the patient who lost her tooth without knowing it. This case (though only one out of many), I feel, ought to be made known, occurring, as it does, in the centre of much medical opposition; and I beg to refer any sceptic to Mr. Mosely, the dentist, of 28, Park-street, and to Miss Smith, of 29, Park-street, Bristol, both of whom witnessed this interesting operation. The members of the profession will perhaps say this is only the effect of imagination. They shall have the full benefit of this opinion. My reply is, that if imagination will allow limbs to be amputated, teeth extracted, and tumours removed, without pain, to say nothing of the most distressing nervous diseases cured, the sooner imagination is allowed to become an active agent of the curative art the better. To medical sceptics I would say, in the language of the late Mr. Chevenis on this subject, "Would it disgrace the greatest man whom England has ever produced, to attempt an experiment or two upon a doctrine which Hufeland, Jussieu, Cuvier, Ampère, and Laplace believed? Nay, would it not disgrace him more to condemn, without knowing anything about what such men knew and believed? Surely, *what great men believe, ordinary men may try*."—HENRY STORER, M.D., 27, Brook-street, Bath.

THE LATE MR. EVERITT.

Although the melancholy visitation which overclouded the last days of Mr. Everitt had removed him from more immediate observation, yet the distinguished position he formerly held as a teacher of chemistry, demands that he should not be allowed to pass away from the scene of life unnoticed and unhonoured. Educated principally in the schools of Germany, he was an enthusiastic admirer of those men who have distinguished themselves by their unwearied industry and accurate observation, rather than by the brilliancy of their discoveries, or the bold inductions which have marked the French and English chemists. He commenced his career in London just at the period when the old system pursued in the medical schools, which allotted to one teacher a vast number of departments, was broken up, and when chemistry was made a separate branch of medical science. Mr. Everitt was first introduced to the pupils at the Little Windmill-street School of Medicine by Dr. Sigmond, when, in compliance with the altered state of teaching, he confined himself to two branches.

Mr. Everitt's introductory lecture gave unbounded satisfaction; it was clear and comprehensive, and although it was evident that his views were principally embraced within the circle of German science, still he exhibited a profound knowledge of the subject, together with the power of explaining his ideas in clear and simple language.

As it was evident that he was calculated not only to teach the elementary principles, but also to attain the highest rank in the science as a professor, he was soon called on to fill other positions. The first was the professorship of chemistry of the Royal Medico-Botanical Society, in which he ably fulfilled the duties entrusted to him, and was the first to disseminate all the novelties which issued from the German school, of which he continued an enthusiastic admirer. The lectures he delivered were explanatory of the new doctrines which were from time to time brought forward, and he contributed to add much to the reputation which was conceded to that institution. He subsequently was called upon to fill the chair of professor of chemistry in the Middlesex Hospital School, and afterwards held the same office in the College of Civil Engineers, and for a considerable length of time was regarded as a man who would soon fill the most distinguished situations in science, but unfortunately a mind of high powers and of great capabilities became un-

settled—whether overpowered by the vast variety of ideas which opened upon him, or whether his nervous system had received some shock, it is difficult to ascertain—but a want of order was gradually observed in the development of his views, an incongruity of expression, and at last such a confusion of ideas as to render him incapable of teaching. This sorrowful state increasing, it was at length found that complete aberration of intellect rendered confinement necessary, and his existence was ultimately terminated; under most melancholy circumstances, in the asylum to which he had been consigned by those who entertained a hope that, by proper treatment, he might be relieved.

Professor Everitt had for some time shown that he was of a highly nervous temperament; but his friends, certainly, had not looked forward to so decided an alteration. The occasion which led to a suspicion of his own doubts as to the state of his mind, was at a meeting of the Royal Medico-Botanical Society, when the noble president, Earl Stanhope, was in the chair, and considerable anticipation had been formed of the information to be gained by a lecture on the cinchonas by the professor. Every thing was prepared, and the experiments had been previously gone through, when, on standing up, he found himself quite at a loss to express himself, and abruptly left the house, with a verbal message that he was not himself. At the school at the Middlesex Hospital, similar occurrences took place; and it was soon found that his fine mind was unhinged, and that Science could no longer hope to derive aid from one of her most zealous admirers. His career, however short, was advantageous to the progress of chemistry; he aided in disseminating the best class of knowledge; and if he has left behind him no memorials which will hand his name down to posterity, at all events he will not be forgotten during the present generation by those who know how to prize talent, industry, and judgment.

UNIVERSITY OF LONDON.

BACHELOR OF MEDICINE.—FIRST EXAMINATION. EXAMINATION FOR HONOURS.—1845.

Anatomy and Physiology; Examiners, Mr. Kiernan and Professor Sharpey.—Thursday, August 14; Morning, 10 to 1.

1. Commencing the dissection at the integuments, and proceeding with it as far as the pharynx, and the bones forming the zygomatic fossa, describe the parts successively exposed in dissecting the space bounded above by the zygoma, below by the base of the inferior maxilla, in front by the anterior margin of the masseter, and behind by the meatus auditorius, mastoid process, and upper part of the Sterno-Cleido-Mastoideus.

2. Give the anatomy of the corpus striatum; describing its situation and immediate connections, and the arrangement of the white and gray matter within it (as seen with the naked eye). Describe also the parts met with in exposing the corpus striatum from the outer and lower part of the cerebral hemisphere.

Afternoon, 3 to 6—

1. Describe the parts (excepting the bones and ligaments) as they are successively exposed in dissecting a portion of the anterior region of the thigh, bounded above by Poupart's ligament, and below by a transverse line corresponding with the lower limit of the insertion of the adductor brevis; the dissection to be carried down to the anterior edge of the gluteus medius, the hip-joint, the obturator membrane, and anterior surface of the adductor magnus.

2. Give an account of the structure and properties of mucous membrane in general, and describe that of the stomach, and of the small and large intestines in particular; the description to include an account of the ultimate arrangement of the blood-vessels, the epithelium, the follicles of Lieberkühn, and the glands of Brunner and Peyer.

Chemistry; Examiner, Professor Brande.—Friday, August 15; Morning, 10 to 1.

1. Enumerate the combinations of chlorine with oxygen, giving their respective equivalents and symbols, the modes of obtaining them, and their characteristic properties.

2. Explain the construction of "Grove's Battery," and the theory of its action in reference to the changes which the fluids employed in it undergo during the passage of the electric current; compare it in these respects with "Daniell's Constant Battery," and with the voltaic battery upon the common construction.

3. How would you separate and determine the quantities of the respective metals in an alloy composed of platinum, gold, silver, copper, lead, and tin?

4. The proximate organic components of wheat flour are starch, gum, sugar, fat, glutine, fibrine, caseine, albumen, lignine. How would you separate these substances, and what is their ultimate composition?

Materia Medica and Pharmaceutical Chemistry; Examiner, Dr. Pereira.—Afternoon, 3 to 6.

1. State the botanical origin and chemical composition of officinal camphor, as well as of Borneo or Sumatra camphor. Describe the method of procuring artificial camphor, and mention the chemical composition of this substance.

2. How would you proceed to detect the presence of arsenic, of lead, and of nitrous acid in commercial oil of vitriol?

3. What are the proper specific gravities, at the temperature of 62° Fahr., of the following substances, according to the London Pharmacopœia: Acidum sulphuricum, Acidum nitricum, Acidum hydrochloricum, Acidum aceticum, Ammoniæ liquor, Ammoniæ liquor fortior, Spiritus rectificatus, Alcohol, and Æther sulphuricus? State, in the language of Sykes's hydrometer, the density of Spiritus rectificatus, Ph. Lond.

4. Forty grains of diluted hydrocyanic acid yield, with a solution of nitrate of silver, a precipitate weighing 7·3 grs., only 5·6 grs. of which are soluble in boiling nitric acid. What is the per centage strength of the diluted hydrocyanic acid?

5. You are requested to describe the method of preparing Sulphur præcipitatum, and to explain the chemical phenomena which ensue; also to point out the nature of the substance with which the officinal preparation is frequently contaminated, the mode of its introduction, and the best method of distinguishing between the pure and the impure article.

6. Describe the effects of strychnia on man and other animals; name the diseases for which it is applicable; mention the circumstances which permit or contra-indicate its use; and state what you conceive to be a proper dose of it, as well as the cautions to be used during its employment.

HOSPITAL REPORT.

WESTMINSTER HOSPITAL.

The Case of Urethro-Vaginal Fistula.—The patient on whom Mr. Brooke operated Monday three weeks for urethro-vaginal fistula (vide *Medical Times, ante*), was made an out-patient on the 18th instant.

The ligatures came away on the seventh day after the operation (Aug. 3), their early separation being probably owing to the unhealthy condition of the structures through which they were passed, as Mr. Brooke remarked that in another case on which he had operated successfully, the sutures remained for twenty-four days, and were then removed, as being no longer required.

The vagina was examined, by the aid of a speculum, on the 12th instant, by Mr. Lynn, under whose care the patient was admitted into the hospital, and by Mr. Brooke, when the fissure to which the sutures had been applied was found to be perfectly closed. The incontinence of urine, however, still continues, in consequence, probably, of the condylomatous condition of the remaining portion of the urethra. This examination was not made earlier, lest any recent adhesions should be disturbed by the dilatation of the canal.

APOTHECARIES' HALL.—Gentlemen admitted Members 14th August, 1845:—Robert Ripley, James Spurr, Thomas Frederick Grimsdall, John Terry.

PLACENTA PRÆVIA.—Mr. Williamson has published a case, in the *Provincial Medical Journal*, of hemorrhage from placenta prævia, in treating which he detached and brought away the placenta some time prior to the birth of the child. The case was successful.

GOSSIP.

M. LALLEMAND, the eminent Montpelier Professor, has been elected to the place in the medical section of the Academy of Sciences vacated by the death of M. Breschet. M. Lallemand has now fixed his residence permanently in Paris. M. Boyer has succeeded M. Breschet as surgeon to St. Louis. Our distinguished contributor, M. Jobert (de Lamballe), declined the post.

Dr. J. Toogood, of Bridgwater, has addressed a letter to the *Dorset Chronicle*, calling attention to "the frequency of deaths arising from the unrestricted sale of poisons to all who ask it." "In Austria," he says, "the apothecary is solely a compounder of physicians' and surgeons' prescriptions. He dare not, under the severest penalties, prescribe even the most simple remedies, nor perform the most insignificant surgical operations. Nay, more; he cannot sell a dose of physic without the written order of the physician or surgeon, who is recognised by the university of his country. * * All poisons are required to be kept under lock and key, and can only be compounded by the head of the establishment. All powerful medicines—as emetics, drastic purgatives, strong mercurial compounds, and all preparations marked thus † in the tax book, are not permitted to be sold without the recipe of an authorised practitioner. Apothecaries known to sell medicines which might procure abortion, without the order of a physician, are punished in the severest manner. * * Both the public on the one hand, and the prescriber and legitimate compounder of medicine on the other, are protected against quacks, mountebanks, patent medicines, wonder-working nostrums, poisonous pills, mineral cosmetics, and the thousand deleterious substances advertised, puffed, and vended, under the name of specifics and panaceas, not only with the *permission*, but frequently with the *authority*, of the state in Great Britain. The public prints are not hired to entrap the ignorant or credulous by lauding empirics and impostors; the public eye is not disgusted by unseemly and disgusting placards, nor modest females insulted by having indecent handbills thrust upon them in the open streets, as occurs daily in this country. Moreover, no one is allowed to sell medicine of any description without a proper education and satisfactory license; and the trade of a druggist is, as it should be, confined to the wholesale vending of medicines to apothecaries. England might and ought to take a wholesome lesson from this well-ordered condition of the present state of pharmacy in the Austrian states." The editor of the *Gateshead Observer*, noticing this subject, well remarks, "If not an exact model for imitation, Austria certainly sets an example of care for the public health which we would do well to follow. We should not be disposed to gag the English quack so despotically as the Austrian; but we would have the state discountenance and discourage him, and give its support and protection to the educated and competent practitioner."

Hubbard, the Leicester stocking-maker (charged with murdering his wife recently), who has, besides his thumbs, five fingers on each hand, is said to have a child similarly malformed.

A correspondent of the *Edinburgh Weekly Register* makes the following interesting observations on the hygiene of railway travelling: "In the medical circles of the metropolis an opinion is fast gaining ground that rapid railroad travelling superinduces attacks of apoplexy in persons predisposed to that awful visitation. Before the deaths of Viscount Canterbury and Lord Bateman—the melancholy circumstances attending which are yet fresh in the public mind—the more distinguished members of the faculty had their attention directed to the subject. Numerous inquests have been lately held on apoplectic persons; and, in the great majority of cases, it has been found that the parties, immediately preceding the attack, had been travelling fast by one or other of the railways. An inquisition just held on the body of a highly respectable tradesman—a copper-plate engraver—presents another confirmation. I give no opinion, but merely state what has taken place, together with the feeling on an important question, which, no doubt, are long will more particularly occupy the attention of the medical profession."

No. 310. **SUMMARY.** Aug. 30.

CLINICAL LECTURES ON SURGERY.

BY M. F. LALLEMAND.

Translated for the Medical Times by JOHN WATERS, M.D. M.R.C.S.E., Ancien Eleve des Hôpitaux, Membre de la Société des Medecins Etrangers, &c. &c.

LECTURE II.

SYPHILITIC INFECTION.

Syphilis may be communicated in three ways. 1. *Directly*—from one person to another. This happens when the virus is introduced into the system by the genital organs; by an absorbing surface, such as the mouth, the anus, the eyelids, &c.; or by a scratch, or any abrasion of the skin.

2. *Indirectly*—by the contact of an intermediate body, impregnated with the virus, such as a glass, spoon, tobacco-pipe, &c.

3. By *hereditary transmission*. In these cases the virus is not introduced into the economy by direct or indirect contagion, but still its action is as formidable. I shall relate the history of a few cases, which will illustrate the mode of infection, as well as the length of time which may elapse before the venereal symptoms declare themselves.

Case.—*Syphilitic Ophthalmia by direct infection.*—Pierre Donniez, ætat. 29, a plumber, came for advice to the dispensary of Saint Eloi, in the month of November, 1843. Two months before (September), he had contracted a blenorrhagia at Barcelona, which he neglected at first, though afterwards he underwent for it several plans of treatment. In the month of October the venereal symptoms appeared in the eyes, to which the patient's fingers had conveyed the matter of the discharge. At present, some chancres are found under the prepuce, which is very narrow; the discharge also still continues. The ophthalmia had produced ulceration in the cornea of the left eye, and a spot on the right. Seton to the nucha; circumcision; pills of Sedillot. Under this treatment, ophthalmia and chancres both disappeared.

This ophthalmia, obviously, was not simply blenorrhagic, like that conveyed to the eyes by the fingers when loaded by the matter of an ordinary discharge; for, in this case, we find also chancres, and the antivenereal treatment induced an equally rapid recovery from both. It offered also very different symptoms from those which characterise constitutional syphilitic ophthalmia, as might be expected from the fact that the virus was here directly transmitted to the eye, not conveyed to it by the constitution. The inflammatory severity and alteration in the cornea is of little or no consequence in the diagnosis.

Case.—*Fissure of the Anus; Three Operations without Improvement; Antivenereals; Recovery.*—A soldier was affected with a fissure of the anus, and was operated on twice before he came to the hospital. I performed on him a third operation, which was as unsuccessful as the two others which he assured us he had undergone. The patient, having been frequently interrogated, denied ever having had connection with women; and, on examining the rectum, there existed a rather copious discharge. Sublimate injections, the introduction of mercurial tents into the rectum, antivenereals internally, soon arrested the discharge, and the fissure quickly cicatrised. Probably this patient told the truth when he asserted that he never had connection with women, but still the affection, in this case, must have been contracted by "direct" means. The fissure was not a simple tear of the rectum, as it yielded to a specific treatment, although three operations had been performed without any such successful result. The pustular forms of syphilis, which are the forms more frequently seen, are generally the consecutive symptoms of a disease introduced directly by the genital organs; and cases are met with where the infection takes place in this way as the result of unnatural intercourse. Examples of this kind, however, are so well known, and their diagnosis is so easy, that they had better be passed over in silence. Here is a singular case of a somewhat similar kind.

Case.—*Venereal Ulceration at the Umbilicus.*—Some years back, I was consulted by a young lady, who had a muco-purulent exudation from around the umbilicus, the smell of which was similar to what is usually known to proceed from venereal ulcerations when found between the toes. Emollients, general and local baths, afterwards tonics and astringents, were tried, with no advantage. My attention was now seriously aroused, and I made the fullest inquiries into the history of the patient. She acknowledged having had intercourse with a young man, who had syphilis, but which had disappeared a short time since without his having submitted to treatment. Fearful of pregnancy, and of contracting the disease, she observed a certain caution, but the seminal fluid was frequently emitted on the umbilical region, and it was since then that this exudation made its appearance. Lotions, with sublimate; antivenereals internally. In a short time the discharge disappeared, the spot whence it proceeded lost its mucous aspect, and the epidermis was restored to its normal condition. Now, since the infected seminal fluid was capable of transmitting the disease through the epidermis to the umbilicus, with what more severity would it not have acted, if it had been left on the surface of a mucous membrane like the vagina? It is highly probable that pregnancy, in this case, would have been attended with the consequences of hereditary syphilis, as we shall by and by shew by cases.

Case.—*Venereal Ulcerations of the Scrotum.*—A young man, fearful of contracting a venereal infection, had recourse to the ordinary mechanical means of protecting himself, and used on this occasion a "double" precaution. No symptoms shewed themselves on the penis, but some venereal pustules appeared on the scrotum, which he could not cover during coition; and these resisted every mode of treatment, till a persevering use of antivenereals was resorted to. The scrotum alone is seldom the seat of primary symptoms, because the infection has readier access to the prepuce or the glans; under peculiar circumstances, cases of this kind do occur, when, if they are small and superficial, they may disappear by the use of baths, a mild regimen, &c.; and may occasion, at some later period, consecutive symptoms, the origin of which the patient is ignorant of.

Case.—*Ulceration of the Upper Lip; Sub-Maxillary Engorgement; Antivenereals; Recovery.*—A soldier presented himself, in the month of January, 1844, with an ulceration of the upper lip, and a considerable engorgement of the sub-maxillary glands. He could not account how he contracted the affection, but the ulcer on the lip offered a characteristic appearance; the edges were hard, everted, &c. When he had taken a hundred Sedillot pills, the ulcer had healed.

The lips have the same absorbing power as the genital organs—the epidermi of these parts—and being extremely vascular and thin, so that the infection is easily communicable. The enlargement of the sub-maxillary glands is analogous to the buboes which come in the inguinal region when the infection is in the genital organs.

Case.—*Ulcer in the Lip of a Cancerous Appearance; different Modes of Treatment; Recovery by the Antivenereals.*—A student, ætat. 17, had an ulcer during the last year and a half on the lip, which was considered cancerous. Every method of treatment that had been put in force had failed. I was consulted, and considered the affection to be of a venereal nature. On interrogating him closely, the young man acknowledged that, returning to college one night, he kissed a prostitute in the street, a short time before the ulcer made its appearance; but as he refused the advances of this girl, he attached no importance to the fact, and passed it over in silence. An antivenereal treatment was followed by a speedy amelioration, and a complete recovery. If the venereal ulcer in this case had been treated as a cancerous nature, it would undoubtedly have degenerated into a fatal condition, for, being already irritated by the application of caustics and other irritants, it had increased rapidly.

Case.—*Ulcer on the Lip of a Cancerous Nature, communicated to Three Friends by the same Woman.*—About twenty years ago I was consulted by a young man from Montpellier, about an ulcer which was situated on the lower lip, and which was considered to be carcinomatous. Excision had been proposed for it as the only chance of recovery. The wound had obviously, however, a syphilitic appearance. The affection had lasted three months, and the patient never had syphilis; he had had no intercourse with a person likely to have disease, nor could he recal any incident to explain the nature of these symptoms, a curiosity for the details of which excited no little investigation among the medical men acquainted with the case. I had great difficulty to induce him to try an antivenereal treatment, but the character of syphilis appeared so evident to me, having had many similar cases, that I enforced on him my own views of the proper treatment. At the end of three weeks the ulcer was healed. At this same period another young man came to consult me, having a wound at the same place, from which he suffered for about the same length of time. He presented the same appearance as the first patient. The same interrogatories won the same replies. The same treatment was tried—as rapid a recovery took place. A short time afterwards a third young man called, who had been sent by his two other friends, to get rid of a similar affection of the lip. The same syphilitic appearance was visible, and from its irritable aspect the same opinion

of a cancerous nature had been formed about it. The same means produced as fortunate and speedy results as in the two former cases. How explain this perfect coincidence in the ulceration of these three young men, all perfectly unacquainted with the way in which they had contracted this disease? If one of them had been infected from drinking out of the same glass, or by smoking the same pipe, or playing on the same flageolet (one of them played on this instrument), the principle of contagion might be communicated. I could not account for the singularity of these cases, until one day I met one of the three friends coming out of a house as I was going in; on meeting me the young man blushed, and appeared ashamed, and when addressed with questions which he knew were not dictated by a foolish curiosity, he confessed that he had been paying a visit to a woman who lived on the second floor of that house. The mystery was now cleared up. I attended in the same house, and on the same story, a patient from Cevennes, whom I treated for the last four months for constitutional syphilis, which was accompanied with ulcer in the throat, and on the inside of the lips. This young girl, ignorant that she could communicate the disease under which she laboured, was courted by each of the three friends separately. Her kisses infected each, for she allowed no greater liberty. Thus their statement was true, that there had been no cohabitation, and although they were on the most friendly terms, they could not account for the simultaneous existence and perfect identity of their disease. They never visited this young girl together, and her appearance of blooming health, and her obstinate resistance to their advances, could not warrant the slightest supposition that an inveterate syphilitic affection existed.

Case.—*A Tubercular Eruption on all the Body, appearing with a Cause; different Modes of Treatment without Success; Recovery by Antivenereals.*—A young medical man of considerable talent observed a number of tubercles suddenly make their appearance on his face, of an extraordinary aspect. They soon extended all over his body. The patient did not recognise the character of the symptoms, notwithstanding his experience, nor did any of the colleagues he consulted. After five or six months of fruitless but different modes of treatment, the symptoms increasing in severity, he came to Montpellier to consult me. The appearance of the tubercular crusts, their obstinacy, their continuance in certain places, although some few had healed, the cicatrices which they left, and, above all, the numberless examples of this kind which had come under my notice, induced me to consider the case of a syphilitic nature. The patient declared that there was no circumstance in his life, that he could remember, to warrant the supposition of constitutional syphilis. An antivenereal treatment produced the complete disappearance of all these symptoms in three months, except the marks left from the cicatrices. Pills of Sedillot, preparation of gold, sudorifics in high doses.

The patient was not aware of what importance it was for his recovery to be able to assign a determining cause. He had taken a long journey to put himself under the care of a master in whom he had the greatest confidence, but all the different modes of treatment that had been tried proved ineffectual, and still he could not recal any circumstance that would warrant him to believe in the existence of constitutional syphilis. We must admit that the infection here took place, as in the preceding cases; the primitive symptoms being trifling and superficial, and disappearing almost immediately without leaving any trace.

Medical men have long been obliged to admit the existence of buboes *d'emblée*. By this term is meant, that the buboes appear where there is no external ulceration, or pustule on the penis, &c. It may have been preceded solely by slight superficial excoriations, which have healed quickly by emollients, and cleanliness. Ulcerations on the skin, pustules, &c., come on after connection. Sometimes twelve or fifteen days pass by between the period of infection and the appearance of primary symptoms, which are always the effect, not the cause. In this way we can understand how their presence is not always necessary to form a correct diagnosis, for the constitution may be infected without the patient being warned by any external phenomenon exciting attention. What we have just said of the genital organs, may be applied with much more truth to the tongue, mouth, lips, in a word to all parts of the body, where the absorption of the virus may take place.

The practical results that may be drawn from these facts, are, that in venereal affections, particularly in the secondary constitutional ones, we must attach more importance to the aspect of the symptoms than to the antecedent history; for patients may be completely unaware how they became infected, even when of no consequence to dissemble. When the symptoms are well characterised, we must not pay attention to the denials of the patients, though in other matters their word is not to be doubted: we should act according to the present indication, particularly when we take into account the anterior courses of treatment they may have undergone without benefit.

Case.—*Indirect Transmission of Syphilis among Three Children.*—In a regiment, garrisoned at Montpellier, three children were entrusted to the care of a sapper, who was labouring under venereal pustules in his mouth. These children made use of a glass and spoon which he was daily in the habit of using; all three presented in a short time pustules on the lips, which quickly assumed a bad character, and only yielded to antivenereal treatment. This mode of transmission being well known, we shall record no more cases of it.

Case.—*Congenital Syphilis; Venereal Ulcers on both Feet; Mercurial Frictions; Recovery.*—A woman came to the hospital of Saint Eloi in February, 1842, to undergo treatment for an attack of intermittent fever. She brought with her at the same time her daughter, aged two years, who for the last six months had ulcers of quite a venereal aspect on both feet. Notwithstanding the frequent denials of the mother, who pretended never to have had syphilis, the child was put under a mercurial course of friction, and the ulcers quickly healed.

Case.—*Syphilitic Ulceration of the Right Side of the Face and Forehead in the Mother—Ulceration on the Child's Buttock at the Age of Ten Years.*—In the month of July, 1844, a woman came to the Clinique, having a large ulcer, which had eaten away the upper part of the right side of the face, from the alæ of the nose to the scalp. The surface was red, bleeding, covered with granulations of a bad appearance, and which poured out a sanious suppuration, and gave at the first aspect the idea of the existence of cancer or lupus. The history, however, proved a venereal origin for these disorders. The patient had syphilis at several different times, and the treatment was ineffectual, because incomplete; after having suffered excessive pain in the head, a small pimple appeared on the face; it ulcerated, grew larger, and gradually covered a surface about the size of the hand. At the same time this woman showed us a little girl, ten years of age, of a lively and intelligent appearance, and of vigorous constitution, who had on the buttock an enormous ulcer, with everted and irregular edges, and a greyish aspect, and at the same time had ulcerations on the labia majora. Six months ago, a small pimple came on the buttock, the child scratched it, and in a short time afterwards the disease had made rapid progress. A furfuraceous eruption of the vulva about the same period was followed by a copious discharge, with excoriations which quickly ran into characteristic ulcers. An attentive examination of the genital organs of the mother, connected with the history and character of the woman, left no doubt about the existence of congenital syphilis, which remained during ten years in a latent state. The mother was treated with Sedillot's pills—afterwards with the iodide of potassium, night and morning, with sudorifics. Emollient poultices were applied to the ulceration, and leeches in the vicinity. The child was also submitted to the pills of Sedillot and to sudorifics, with local injections of a solution of bichloride of mercury. When I gave up the cases to Dr. Franc (August, 1844), these two patients had already experienced a considerable improvement, and the ulcers gave every promise of a speedy cicatrisation.

[Dr. Waters is indebted for these lectures to the labours of M. Hermann Kaula, to whom the profession is under no slight obligations for thus furnishing it with the latest views on surgical medicine taught by his distinguished friend and preceptor. Perhaps it should be added, that the forms of disease here treated on, are those to which M. Lallemand has given such special and successful attention.—Ed.]

ON STRICTURE OF THE URETHRA, AND ITS TREATMENT.

By LEROY D'ETIOLLES, M.D., Member of the Academies of Brussels, Madrid, and St. Petersburgh; of the Imperial Society of Physicians at Vienna; of the Royal Medical Society of Edinburgh; of the Medico-Chirurgical Society of Berlin; of the Society of Medical Sciences at Lisbon; of the Royal Society of Arts and Sciences at Nancy; of the Medical Societies of Antwerp, Bruges, Ghent, Guadalaxara, Lyons, Malines, Munich, Nancy, Willebroek, and Paris; and of the Council of Health at Brussels.

Condensed from the original by JOHN FOOTE, Esq., Member of the Royal College of Surgeons of London; Senior Honorary Secretary of the Royal Medico-Botanical Society of London; Corresponding Member of the Sociedade Pharmaceutica Lusitana; of the Société Industrielle at Angers, &c &c.

(Illustrated by wood-engravings.)

Strictures of the urethra deserve the utmost attention from surgeons, on account of their frequency and severity. They may prove dangerous when they are neglected, not only by causing occlusion of the canal, but also by becoming the primary cause of numerous changes of structure, which, misunderstood and neglected, often place life in danger. The most common consequences of the difficulty in the emission of urine which they cause are, ulcerations of the urethra in that portion of the canal which is immediately behind them, urinary abscesses and fistulæ, inflammation of the prostate, stone, catarrh of the bladder, and nephritis. Other alterations may also be produced, but those which we have enumerated are more than sufficient to demonstrate the importance of the study we are about to undertake.

Before touching, however, upon that part of my inquiry, it will not be altogether useless to begin by examining the normal condition of the urethra, in order that its pathological state may be afterwards better understood.

Anatomical considerations.—The urethra is generally divided into the spongy, membranous, and prostatic portions. Some, however, consider the bulb as a fourth part, while others propose to divide it into two parts only—the one fixed, limited by the sub-pubic ligament anteriorly, and by the neck of the bladder posteriorly; the moveable portion extending from the sub-pubic region to the extremity of the penis. This division is erroneous, inasmuch as the pathological changes which take place in the form and length of the canal occur most frequently in that part which is wrongly described as fixed. This part, in fact, often undergoes an elongation of from one to five centimetres, from hypertrophy of the prostate, which, at the same time, causes an increase of the curvature, and it is also often pressed out of its natural direction by the abnormal development of one of the prostatic lobes. The first division into three regions ought, therefore, to be preferred, because, in fact, these three portions are well-marked by the texture of the tissues which surround them.

The urethra presents three curvatures according to some, but only two according to others; but with respect to catheterism, one only is to be regarded, since, in consequence of the extension of the penis, the urethra is straight as far as the bulb, where the curvature commences, which terminates at the neck of the bladder. Besides its natural inflexions, however, the urethra may present accidental ones, having for cause, for example, the unequal increase of the lobes of the prostate, the unequal development of the corpora cavernosa, tumours developed in the perinæum, fistulous canals, the sequelæ of urinary abscesses, and old and large herniæ and hydroceles. There is yet another cause of the deviation of the canal, which is yet worse than the other,—I mean the false passages made during previous catheterism.

Surgeons differ as to the length of the urethra; thus, Boyer assigns it from eleven to twelve inches, whilst Malgaigne looks upon six inches as the

maximum. These differences of opinion may perhaps be explained by the peculiar circumstances in which the observers were placed. M. Malgaigne, for example, having experimented on the dead body, found the urethra to be very short, for, on almost all bodies, the emaciation which precedes death, and the contraction of the tissues which follows it, so contract the urethra that we may, in a large number of the bodies of men, practise catheterism with the female catheter. The length of the urethra can be ascertained only on the living subject, and the best means to do so is to judge by the depth at which the urine can be drawn off by a gum elastic catheter —a proceeding which every good surgeon employs to learn at what depth a catheter should be fixed to draw off the urine without injuring the parietes of the bladder. The distance from the part corresponding to the meatus urinarius to the eye of the instrument, will give the length of the urethra, the penis being in the flaccid state the while. Civiale, who measured the urethra in this manner, gives it a medium length of six inches and a half in the living, and five and a half in the dead, and Velpeau says, "at six inches the bladder is entered." If this were the case, the greater number of strictures would be at the neck of the bladder, for they say, and say truly, that they are mostly situated at from five inches and a half to six from the meatus urinarius. Watheley gives a medium of eight inches, five lines, as the result of fifteen observations on the living subject. In my opinion, founded on more than a hundred observations made on the living, the medium length of the urethra is about eight inches.

It seems to me that the differences of races produces notable differences in the length of the urethra; I was struck with the shortness of the instruments and catheters of Jacobson, the surgeon, of Copenhagen, and since then, in the greater number of the Northmen I have had occasion to catheterise, I have found the urethra rather shorter than in the inhabitants of the South. I have, however, rarely found it to be less than seven inches, and, on the contrary, have often found it to be ten or eleven inches long, and even more. A short time ago I sounded four patients in one day, whose urethræ presented the latter dimensions.

As we are not generally called upon to catheterise the healthy urethra, it is of more importance to study the dimensions of this canal in the state of disease than in that of health, and especially on the dead body. As the prostate of old men is much larger than at the other periods of life, the urethra is consequently so much the longer; when retention of urine occurs, which is very common in old age, it is generally dependant on a greater degree of hypertrophy, or on the development of the pathological lobe, whence there results another increase in the length and curvature of the canal. Whilst the prostate, enlarging as old age comes on, raises the neck of the bladder, the symphyses pubis and the sub-pubic ligament also acquire a greater height, thus depressing the commencement of the membranous portion of the urethra, and adding to the curvature of the canal. The following are the medium results of the measurement of the height or antero-posterior diameter of the symphysis and sub-pubic ligament, which I made and published eighteen years ago:—

Age.	Men. (millimetres.)	Women. (millimetres.)
12	31	31
14	33	33
20	36	36
28	40	36
34	42	36
45	45	38
60	50	43
70—80	50	50

This table also shows that the height of the symphysis, which is the same in both sexes in infancy, presents differences at the adult period of life, which diminish in extreme old age; these differences, and still more the existence of the prostate in man, destroy the resemblance which was supposed to exist with regard to catheterism between the intra-pelvic portions of the urethra in both sexes.

A marked degree of embonpoint often gives rise, long before old age, to an increase in the length and curvature of the urethra, through the interposition of the fatty tissues around the rectum and neck of the bladder. I have often noticed this in fat, calculous subjects, in whom the increased length of the canal could only be attributed to the elongation of the penis, which generally disappears in the midst of the fat of the pubes. The curvature is sometimes enormously increased, so that in the greater number of cases of enlargement of the prostate, and in very fat men, catheterism is most readily practised with catheters having a curvature of three inches and a half. This curvature of the membranous and prostatic portions, however great it may be, is nevertheless effaced when the straight portion of the sound has passed through the neck of the bladder, but this depression is not effected without violence; so that the measures of the depressibility of the neck obtained on the dead body by M. Malgaigne are not applicable to the living. After having introduced a straight sound into the bladders of several dead bodies, he found that the medium of the inclinations furnished by these experiments gave an angle of 45° with the axis of the body, lying flat on the back. The angle is generally much more acute in the living; the direction of the catheter is often parallel with that of the body, and when engorgement of the prostate is conjoined with great embonpoint, the external portion of the instrument is often below the horizon.

If the entire length of the urethra differs, as has been already shown, it will be readily conceived that the length of each of its regions may vary. That of the spongy portion is from five inches and a half to six inches; the membranous portion is generally one inch; and the prostatic from twelve to fifteen lines. But the natural length of the penis causes notable differences in the spongy portion, and pathological changes cause equal differences in the prostatic portion. Among the morbid preparations which I have presented to the Musée Dupuytren, there is one in which the prostatic portion is three inches long, and the spongy portion four inches only.

Opinions differ also with regard to the diameter of the urethra; the elasticity of the canal renders it difficult to ascertain it correctly. The only way to effect this object is to inject the canal with a substance which will harden in it, and form a mould, and even that, as the tissues of the canal are extensile, will be less a test of its diameter than of its elasticity. The results of experiments thus conducted show that the narrowest parts of the urethra and the least dilatable are—the meatus urinarius, the commencement of the membranous portion, and the point which corresponds to the anterior third of the spongy portion. Nevertheless it is worth notice with regard to the meatus urinarius, that its form presents various anomalies; sometimes the contraction exists only at the orifice of the urethra, and the canal is suddenly dilated afterwards; a second contraction sometimes exists seven or eleven lines further on, the intervening space being called the fossa navicularis; sometimes the narrowing exists in a continuous manner for four or five lines, and there are then no traces of the fossa navicularis, and the orifice of the urethra occasionally presents the appearance of a funnel, the wide part opening outwards, the narrowest point being at the depth of three or four lines. These different conditions of the meatus urinarius are of importance with respect to catheterism, the treatment of stricture of the urethra, and to lithotrity.

The vesical extremity of the urethra is occasionally suddenly contracted by the prostatic projection, which M. Amussat has incorrectly called the pyloric valve. The neck of the bladder sometimes, instead of being contracted, presents an infundibuliform evasement; this happens when the portion of urethra, behind very old strictures, has been dilated by the retention of urine. There is generally then incontinence of urine.

The natural dilatation of the neck varies at different periods of life; it is very great in the child, whence results the ready and frequent admission in it of calculi, or of fragments of calculi, thus constituting one of the principal obstacles to the use of lithotrity in infancy. The dilatability of the neck is lessened when the prostate is hypertrophied; nevertheless, even under those circumstances, it may admit bodies of half an inch diameter, of which I have assured myself several times during the hypogastric operation of lithotomy, by introducing my finger into the neck without difficulty, either to remove fragments of calculi, or to seek for the cause of a retention of urine, complicating the case, and to relieve it.

The urethra is much larger in two situations than in the other portions of its extent. These two points are the bulb and the centre of the prostate. Their extensibility exists not only on the dead body, but also on the living, so that, frequently, after lithotrity, fragments of the calculus are stopped there, without in any way interfering with the passage of large sounds. The enlargement of the bulb exists principally in the under part of the canal, where it causes a sort of *cul de sac*, in which Wilson supposes the semen to be retained for an instant before it is expelled by the contraction of the bulbo-cavernous muscles. A practical consideration resulting from this is, that false passages must be more common at this part, on account of the sudden contraction of the membranous portion following the enlarged bulb, and because the urethra here begins to bend upwards. This membranous portion, which, at first sight, might be regarded as the most extensile, on account of the muscular tissue which surrounds it, nevertheless resists a sudden, but not a slow and sustained dilatation. It is not a rare thing to see calculi which have been stopped here, become very large, or, when a stricture exists at the junction of the bulb and the membranous portion, to find the part of the bulb behind the stricture acquire a considerable size by its distension by the retained urine; so that both Wilson and Civiale were right, the one in stating that the membranous portion was very slightly distensile, and the other that it was very much so. They ought, however, to have noticed the slowness and the rapidity of action of the dilating agent.

In all works on surgery, when treating on the anatomy of the urethra, it is recommended to pass the catheter along the upper paries of the canal, because all the obstacles to its passage are met with on the lower, such as the cavity of the bulb preceding the sudden contraction of the commencement of the membranous portion, the projection of the verumontanum, the prostatic excavation, and the bar at the neck. This rule is of the greatest utility as respects the point of junction of the bulb with the membranous portion, there being a difference of two or three lines in their level, so that if the point of the catheter were passed into the cavity of the bulb, and force employed, a false passage would be made; it is, therefore, requisite to raise the point of the instrument towards the upper paries; but too much force must not then be used, as it may be caught against the sub-pubic ligament, and the urethra bruised, or even lacerated.

The structure of the urethra varies in its different regions, all of which are lined by a mucous membrane, which, although a continuation of that of the bladder, is smoother, more resisting, and more vascular. It forms little folds, which, during catheterism, must be effaced by extending the penis, as otherwise, with a conical, or very small catheter, the point may be caught in them, and thus simulate stricture. Natural valves have been met with in this membrane, which are not effaceable by extension of the penis, but they are not so frequent as they are supposed to be, and the bridles and projections of small cicatrices have probably been mistaken for them. They are generally met with at the junction of the membranous portion with the prostatic, and at the deep edge of the fossa navicularis, an inch from the meatus urinarius. Lacunæ, known by the name of the *sinuses of Morgagni*, are also met with in this membrane, and are sometimes so large as to catch the point of a small catheter, and give rise to the belief in the existence of a stricture. They are most numerous about the bulb. Canals also open into the urethra, and if their orifices are patent the catheter may enter them, and give rise to error; when the verumontanum and the crista galli are much developed, if they do not prevent the passage of the catheter, they may render it difficult.

Some authors admit the existence of muscular fibres throughout the whole length of the urethra; among these are J. Hunter, Bauer, Wilson, E. Home, and Guthrie; others, such as Bell, Shaw, Moreschi, and Panniza, deny it. They are not found in man, but are supposed to exist by analogy with the greater animals, as in the horse, in whom muscular

fibres, apparently a continuation of the bulbo-cavernous, extend over the whole length of the free surface of the urethra; but these are external to the corpus spongiosum, and their action is to retract the penis within its sheath. There are not any muscular fibres around the mucous membrane, any more than in man, as M. Leblanc, M. Pégu, and myself, have ascertained. The urethra nevertheless aids in the expulsion of the urine, and occasionally expels catheters when not secured; this may be explained by the turgescence of the spongy tissue, without admitting the existence of muscular fibres. The catheter, instead of being expelled, is sometimes drawn into the bladder by a sort of aspiration, as it were, caused by the contraction of the longitudinal fibres of the bladder, which extend as far as the commencement of the membranous portion of the urethra; it rarely happens except when the organ is diseased and empty.

The urethra does not possess any proper muscular fibres, and the spongy portion is entirely without any; but in the prostatic and membranous portions the mucous membrane is enclosed by a muscular layer, the prolongation of the fibres of the bladder, which terminate in a sort of fibrous ring; it is confounded with the tendinous fibres of the muscles attached to the bulb, so that it may almost be said that the first neck of the bladder exists immediately behind the bulb. In fact, when in catheterism the instrument has reached this point, an inclination to pass water is immediately felt. The muscular contraction seems also to make the commencement of the membranous portion a door of the bladder, as it were, since, if it does not prevent the escape of liquids from within, it at least opposes their entrance from without. Who has not observed, when using injections into the urethra, that the liquid returns without passing beyond the bulb, even when it is carried so far by a catheter; but if the eye of the catheter pass the commencement of the muscular part, even by a single line, the liquid passes into the bladder, and overcomes the resistance of the true neck without difficulty. This fibro-muscular orifice does not prevent the entrance of injected liquids only; soft and flexible catheters are in some cases passed through it with difficulty; they must be provided with a stylet, and their point pressed against the orifice until the slight but sustained pressure has overcome the obstacle. This muscular contraction is caused, not only by the terminal ring of the fibres of the bladder, but also by the bulbo-cavernous, the transverse perineal, and the external sphincter of the anus, which, passing from different origins, are attached to the commencement of the membranous portion of the urethra, and draw it in different directions. Thus is produced that obstacle to the passage of instruments, which is called spasm of the urethra. Its occurrence has been explained by the presumed existence of circular fibres from the bladder accompanying the longitudinal, but their existence is entirely fictitious, nor is it necessary to explain the cause of the spasm, which always takes place at the commencement of the membranous portion. There are certainly almost annular fibres in another part of this region, but they belong to Wilson's muscle; they are external to the muscular layer, which forms an envelope to the two deep-seated regions of the urethra, and spasm is not often observed in the part where it is found.

The prostate gland, which sometimes completely, and at others incompletely, surrounds the vesical extremity of the urethra, is subject to an enormous increase of size, to partial pathological developments, which deform the canal, cause it to deviate from its position, or to become narrow, close, or mask the vesical opening, affect the emission of urine, and often completely suppress it, constitutes one of the most serious complications of stricture. These changes of structure in the prostate will be the subject of a special monograph.

From the bulb to the meatus urinarius, the urethra is principally formed by an erectile spongy tube, to which the mucous membrane is united by a fine and close cellular tissue, which does not appear to admit of extended gliding motion; so that the very great mobility of strictures must be attributed to the elasticity of all the tissues which enter into the composition of the urethra, and not to the gliding of the mucous membrane, for when the latter has been torn, or destroyed by syphilitic ulceration, or by caustic,—when the spongy tissue which enters into the formation of the cicatrix is intimately united with it, the mobility is still the same. The spongy tissue imparts to strictures something of its nature, so that they partake at the same time of the nature of inodular and of erectile tissues; these are the most difficult to cure.

The dimensions and shape of the prepuce, and the size of its opening, have a great influence on the production and treatment of stricture; balanitis, gonorrhœa preputii, and phymosis, are caused by narrowness of the opening; inflammation sometimes diminishes it to a point, so as to admit only a very fine probe, and gives rise to retention of urine. I have seen many such cases, and by and by I will give several remarkable examples.

Among the malformations of the urethra, there is one which it is important to study, on account of its frequency,—of the impediment it offers to the urinary and generative functions, and because it complicates the treatment of stricture; I am speaking of hypospadias. With regard to the other malformations, such as epispadias, and double urethræ, it is sufficient to allude to the possibility of the occurrence of such singularities.

The sensibility of the canal is not the same in all the regions. This it is especially necessary to bear in mind, for we might sometimes suppose we were touching a diseased part from the severity of the pain, whereas in fact the part is healthy, but possessed of great sensibility. This is especially remarkable at the meatus urinarius, the neck of the bladder, and at the bulb. It is hardly requisite to say that the degree of sensibility and the manner of complaining will vary in different persons. The sensibility of the canal is, however, soon blunted, so that certain operations can be performed, which at first sight seemed to be impracticable. Sympathetic irritation is also experienced at the meatus urinarius, and has been regarded as indicative of irritation at the neck of the bladder, caused by the contact of a calculus. It is, however, equally sympathetic of irritation in all parts of the bladder; it occurs where there are encysted calculi, when the neck is in no way in contact with the foreign body; gravel and even calculi in the kidney occasionally produce it. This sympathetic pain is modified according to the kind of irritation of which the bladder is the seat; it is felt after passing water, and resembles a painful itching when there is a calculus; it is a burning sensation, and occurs principally at the commencement of the evacuation, when there is vesical catarrh. In this respect there is a sort of reciprocity; emollient applications to the end of the penis and local baths diminish or calm the pain of stone in the bladder; in the operation of lithotrity, where a large instrument, by which the meatus is distended, is used, we may expect to find the bladder affected with contractions which impede the manœuvre, and may compromise its success.

(To be continued.)

PATHOLOGY OF EXPECTORATION.

By S. Wright, M.D., Edin., F.S.A.

Physician to the Birmingham General Dispensary, formerly Senior President of the Royal Medical and Royal Physical Societies of Edinburgh, &c. &c.

(Continued from page 406.)

The commencement, as well as the continuation of the second stage of phthisis, is more marked than any other period of the affection by intercurrent bronchitis or pneumonia. These temporary accessions of more active disease may continue for only a few hours, or a few days—they may occur only once, or may return many times during the progress of the original malady. They are generally distinguished, though in a somewhat modified degree, by correspondent changes in the sputum, but these should only be relied upon when assisted by the services of the stethoscope. Individually, these sources of diagnosis are faulty, when an acute disease, like inflammation, supervenes upon a chronic one, like phthisis; unitedly, they are of more substantial value. The peculiarities of sputum which indicate bronchitis or pneumonia, have been already detailed to the full.[1] If along with either of these we find an aggravation of cough, an increased difficulty of respiration, especially on lying down, an augmentation of pain, and a sense of infarction in the chest, bronchial breathing in its lower portions, and a mucous, muco-crepitant, or actually crepitant râle, bronchitis or pneumonia may be pronounced. Nor is it uncommon, whilst the superior portions of the lungs are being destroyed by a slow process of tuberculisation, for the inferior parts of these organs to become once, or oftentimes, the seat of active inflammation. In some cases, indeed, a sudden bronchitis or pneumonia will anticipate the career of consumption, and carry off its victim at a few days' warning.[2]

The softening of tubercles in the lungs, which commences the third stage of consumption, is chiefly characterised by an aggravation of all the previous symptoms. The patient becomes more feeble and feverish at intervals; he is generally irritable and fretful; he perspires profusely, and is frequently seized with rigors; he coughs oftener, more urgently, and seldom without accompanying pain, referred either to the top of the sternum or to underneath one or both of the clavicles. Sometimes, in a paroxysm of coughing, a vomica will suddenly burst and discharge its contents almost at a single gush. If a blood-vessel of any size be implicated in the rupture, the patient may bleed to death in a few seconds. This is not an uncommon occurrence. Again, only a small quantity of blood may be expectorated along with the matter of vomica, and hemoptysis may follow at intervals during the remainder of the patient's life; but vomicæ often burst without any accompanying or subsequent pulmonary hemorrhage. The length of time which tubercles take in softening, and the period which intervenes between their complete disintegration and their expulsion from the lungs, are very variable, and dependent upon a number of circumstances. Hence, the evacuated matter is liable to much difference, both of nature and appearance. Most commonly it consists of pus, mucus, shreds of membrane, the debris of tubercle, and blood. I have seen it when these several substances were perfectly natural-looking, distinct from each other, and entirely free from offensiveness; and, again, I have met with it consisting of a mass of corrupt materials, grumous and filthy, and discovering no traces of genuine pus or tubercle. In such cases, the matter has obviously lain long enough, not only to soften, but to advance considerably in decomposition. I have almost invariably observed, in instances of this sort, that the patient has sunk rapidly after the rupture of the vomica, and the parietes of the latter have consisted of corroded, ragged pulmonary tissue. Vomicæ, on the contrary, that are left by the evacuation of less corrupt substances, are generally afterwards lined by a membrane which protects the contiguous pulmonary structure, and in some measure relieves the bronchi of irritation and of excessive secernent action, by itself becoming the future source of discharge of pus or tubercle.

The physical signs which indicate tubercular softening in the lungs, are, increased depression in the infra-clavicular, supra-clavicular, claviculo-

[1] I have generally observed, however, that in pneumonia intercurring with phthisis, either in its earliest or its latest stages, the expectoration, additionally to being *rusty* from a *uniform* admixture of blood with its mucus, has also been more or less marked by *free* blood either in patches or streaks; just the bloody expectoration, in fact, that we find in phthisis unconnected with any inflammatory condition. I have known this bloody sputum to be consequent upon pneumonia intercurrent with commencing phthisis, and, after the subsidence of the inflammation, never again to make its appearance during the protracted continuance of the fatal disease.

[2] I have just attended, with Mr. Carter of this town, a patient, a female ætat. 18, who died in three days, of pneumonia suddenly intercurrent with phthisis of four months' standing. The immediate cause of death was asphyxia, as might naturally be expected, for what portions of the lungs were untouched by tubercle were solidified by inflammation, so that respiration, slowly increasing in difficulty, at last became impossible.

axillary, and supra-scapular regions (I have enumerated them in the order of their frequency); diminished motion of the ribs, especially observable at the summit of the chest; stroke-sound of the chest, superiorly, dull, short, and less resistant than previously; auscultation under the clavicle, and in the claviculo-axillary space, discovering all sorts of confused sounds—humid, crackling, bubbling, blowing, and semi-cavernous. The heart's action is generally audible as before, but with less intensity and distinctness, being irregular, and, as it were, muffled. Bronchophony and bronchial cough increased, but the sounds more irregular and variable.

It has been attempted by more than one writer to give a clear and positive catalogue of percussive and auscultatory sounds distinguishing the stage of tubercular softening. My experience leads me to doubt the practicability of any such thing. We are acquainted, and somewhat precisely, with the physical signs which denote the first and the last stages of phthisis; and were the stage of tubercular softening an intermediate one, specific and invariable in its features, we might then pronounce with certainty concerning it. But such is not the case. At the very commencement of softening, the sounds are scarcely distinguishable from those of the preceding stage, whilst at its termination they approach, nearly or entirely, to those of the last stage. Between these two there is every variety of sound, according to the extent and completeness of the softening and disintegration, the degree, the irregularity, and the amount, of liquidity of the tubercular matter.

As the softening of pulmonary tubercular matter commences the third stage of phthisis, so also does the evacuation of that matter complete this stage, in so far as the affected portion of lung is concerned. But with the formation of a single cavity, the diseased action is not always terminated; for though, in some rare cases, the cicatrisation of the cavity, or the lining of it by a membrane which after a time ceases to secrete, may be a means of prolonging the patient's life, or of saving it from a sacrifice by this disease (phthisis); and in other cases, and more commonly, the patient sinks after the first occurrence of tubercular softening, and the post-mortem discovers a solitary vomica; yet it more usually happens that, one cavity having been formed, others shortly succeed it, or miliary tubercles that were stationary advance to maturation, or fresh crops of tubercle are deposited. According as one, or other, or all, of these morbid states and functions prevail, will the physical and other local indications of disease vary and be multiplied.

It remains for us only to notice the signs and symptoms which distinguish a pulmonary cavity, or cavities. The sputa are liable to some variation. Whilst the expectoration of tubercular matter is not necessarily a proof that tubercles exist in the lungs, or that these organs are in anywise diseased, so is the absence of purulent or tubercular sputum not a certain assurance that the lungs are free from cavities. I have known a man, with a cavity at the summit of each lung, to expectorate nothing but mucus for weeks together. This chiefly happens when the membrane lining the vomica ceases to secrete, and becomes, as is not unusual, tough, dry, and coriaceous. If the lungs be not further injured or diseased, and the system not materially debilitated or depraved, the bronchi are apt merely to discharge in increased quantity their natural fluid. If the lining membrane of the vomica be entire, and continuous in secernent functions, then the sputa will consist, for the most part, of genuine pus, with, perhaps, occasionally a little crude or softened tubercle, and, more frequently, a little frothy mucus derived from the trachea or bronchi. All these substances may be discharged together, or any one of them perpetually, or at intervals. If the vomica be destitute of a lining, wholly or in part, the pus, if any be expectorated, is derived chiefly from the bronchial membrane; but in these cases genuine pus is rarely spit; the matter is mostly ichorous, or sanious, and issues from the ragged and unprotected pulmonary tissue left by the discharge of the softened tubercle.

The breaking up of tubercular matter in the lungs, and the consequent formation of a cavity or cavities, gives rise, as I have said, to a great number of curious and complicated auscultatory sounds. As the cavity becomes perfected, and emptied of its contents, these sounds become fewer and more constant, and finally pass from a humid, gurgling, clicking, blowing, or cavernous rhonchus, to complete pectoriloquy—chiefly heard in the infra-clavicular, claviculo-axillary, or supra-scapular region. The sound is generally very circumscribed, but is sometimes of large extent, and of variable intensity and distinctness, from the communication of cavities formed simultaneously or in succession, or from the burrowing and spread of the original cavity.[3] Distinct pectoriloquy, however, is often masked by the presence of fluid (pus or mucus) in a vomica, which fluid necessarily complicates with the proper sound a variety of rhonchi. The integuments covering the affected parts are observed to be more flaccid and sunken than before,[4] they resist percussion more firmly, and give the same dead sound as previously, but it is of shorter duration. In very rare cases, the sound elicited by percussion is even more loud and hollow than natural. If this be not connected with puerile respiration over the situation of the cavity, it will be found that the latter is very large, and the noise produced by striking over it will be clinking or amphoric.

Pathology.—We have already sufficiently discussed the pathology of tubercle, both as regards the perverted function to which the genesis of tubercular matter is owing, and the constitutional circumstances with which it is connected. The morbid appearances of pulmonary consumption are, of course, very variable. If complicated with tracheal or laryngeal phthisis, in the trachea or larynx will be found more or less ulceration, and, perhaps, redness and tumefaction of the membrane, diffused or in patches. The lungs generally display one or more cavities, softened tubercles, crude tubercles, and miliary tubercles. Sometimes vesicular emphysema is met with, here and there, in the neighbourhood of cavities, and oftener, there will be seen circumscribed portions of lung, congested or emphysematous. Very rarely, a cavity will be found in one, or in each lung, and not any other indication of tuberculous disease exist throughout the pulmonary organs. I have seen more than one case of this kind. Again, miliary tubercles alone will be found occupying a greater or less extent of the tissue of the lungs, or only matured (crude) tubercles may be discoverable. Adhesions of the pericardium, or pleura, and effusions into the cavity of the chest, with other like adventitious morbid appearances, of course depend upon circumstances. There can be no doubt that patients afflicted with phthisis often die from mere asphyxia, the consequence, simply, of the minute bronchi being obstructed with tuberculous substance, or of the greater portion of the parenchyma of the lungs being loaded with it. In the latter case, the amount of tubercle must be very great, and its diffusion very general, because the lungs, owing to the supplemental aid which they can receive from the liver and skin, are capable of sustaining life by only a small portion of their natural amount of substance. I possess a section of the lower lobe of the right lung of a man who died of phthisis; it is a complete mass of tuberculous matter, as also was the whole lung itself. The left lung was pervious to only a small extent. The patient died comatose. Such cases are not uncommon; but it more frequently happens that the patient is destroyed, not by the injury inflicted upon his lungs, or a diminution of the accustomed function of the latter, but from that constitutional deterioration which both commences and completes the ravages of phthisis.

Treatment.—The treatment of consumption, whether commencing or confirmed, is of two kinds, local and general; but only in the incipient stage of the disease do remedial measures seem to have any chance of success. In the advanced stage we can do little more than offer a palliative to relieve the tedium and agony of lingering dissolution. True, it has happened that the most desperate and seemingly hopeless cases of tubercular consumption have rallied for a time, or have even recovered; that is, existence, though grievously infirm, has been unaccountably prolonged, and the patient, after a lapse of some years, has died of another disease. These are miracles of nature, not of art. It may happen, in the course of an extensive practice, that a man may meet with such a case as this, or, indeed, more than one; but if he be a wise man, he will not flatter himself that any of the credit of the cure is his own property. From the most extreme state, Nature will often raise and relieve herself, and we, in officiously helping her, are too apt to think that our knowledge and nostrums have been the source of her salvation.

Miliary tubercles may be deposited, more or less extensively, in the lungs, and give rise to all the concomitant signs and symptoms of phthisis, and instead of maturating and softening, may either be absorbed, or so hardened and semi-petrified by an accession of calcareous matter, as to remain dormant and harmless for any length of time. It is not a strange fact in morbid anatomy for a body, quite unsuspected of any phthisical taint, to discover traces of cartilaginous-looking, or calcareous tubercles in the lungs. In other instances, miliary tubercles will be aggregated in some portion of the pulmonary tissue, will maturate, soften, and leave a cavity. This cavity will at length become lined by a membrane, condensed and organised from the lymph effusion of the exposed vessels, and the membrane, at first secreting pus, will finally, from the subsidence of inflammation and congestion around it, secrete only mucus, or discontinue to secrete altogether. The patient, under every apprehension and prospect of phthisis, will mysteriously get well. Another case, similar in its outset, will spontaneously recover by a cicatrisation of the cavity, or a closure of it by bands of condensed lymph. Such cases are rare, and rarer still are those in which more than one cavity in the lungs has been thus healed, or rendered harmless, and its threatened victim saved, even against hope. Sometimes, after the deposition of tubercular matter in the lungs, or after the formation of a cavity by the softening and escape of this matter, further pulmonary mischief will be prevented by a derivative morbid action. Tubercular substance will aggregate in remote places; it may be where little comparative injury results from its presence, as in the mesentery, or where the consequences are fatal, as in the implication of some organ essential to life. In most such cases, however, the progress of morbid action in the lungs is seen to have been completely arrested. The following example, one of the most remarkable I ever met with, occurred in the course of my dispensary practice, about two years and a half ago. The patient, previously to my attendance, had been for some months under the care of Mr. Carter, the resident surgeon of the Birmingham General Dispensary:—

Henry Jeffries, a thin, pale, and weakly lad, became the subject of cough and profuse expectoration at the age of seventeen; he was also troubled with pain in the chest and in the left side, night perspirations, and loss of substance and strength. After these symptoms had continued some months, he was seized with occasional pains in his head; he became irritable, and sought retirement; his appetite was regular and good, but he frequently vomited his food, with scarcely any nausea, and without pain. His ailments persisted, with a slight increase of severity, for eight years, when his right side became paralysed, and he lost the sight of his left eye. His cough, which had before been almost constant, now decreased in severity and frequency, and the habitual purulent expectoration was exchanged for an occasional discharge of pus, alternating with an abundant frothy mucus. For three years previously, his paralysis had been threatened by temporary and partial loss of sensation and motion in his right side, and dim, irregular vision in his left eye. At the time of my seeing him, four months before his death, he was completely paralysed on his right side, and blind of his left eye, the pupil of which was widely dilated and immovable; the corresponding side of his face was drawn, and the opposite eye afforded only indistinct and con-

[3] *Bruit de Pot Fêlé* of Laennec.

[4] This is not always the case. I am now attending a female in the last stage of phthisis—there is a large cavity at the summit of each lung—and yet, a line stretched from either nipple, to the centre of the corresponding clavicle, touches uniformly the intermediate portion of the chest.

fused vision. He was fretful and irrational at times, but was never totally insensible until thirty hours before his death, when he became comatose, and never recovered his intelligence. He coughed frequently, and spat frothy mucus, and very rarely a little pus. Pectoriloquy was clearly heard under each clavicle and in the left supra-scapular region; bronchial respiration and voice were recognised in places over the greater part of his chest; and in other situations there was an unusual hollowness on percussion, and puerile respiration, with prolonged expiratory sound, and various rhonchi—humid, crackling, sibilous, and sonorous. His pulse was quick, feeble, and intermittent. Remedies were unavailing, and he died apoplectic on the 27th of October, 1842.

ON MERCURY IN SECONDARY SYPHILIS, WITH GREAT CONSTITUTIONAL DISTURBANCE.

By GEORGE SAYLE, M.R.C.S., &c., King's Lynn, Norfolk, formerly Curator of the Anatomical Museum in St. George's Hospital School.

Medical men are nearly all agreed, that an emaciated, irritable constitution from secondary syphilis, the system having been under the influence of mercury for the primary disease, will scarcely admit of that medicine being administered, or, at any rate, carried far enough to produce ptyalism. Taking a complete view of the following case, there can be little doubt of its true venereal character; and it also strongly illustrates a fact I have often before observed, that, in secondary syphilis, the eruption commences with the most simple, and rings the changes up to the worst form, unless previously checked by proper remedies.

I do not intend to consider the propriety of administering mercury in primary or secondary syphilis, but, unless constitutional symptoms forbid, I always place my patients gradually under its influence, and keep them so for a fortnight or three weeks after the chancre is cured, according to the severity or tendency of the latter to heal. This practice appears to produce no injurious effects upon the patient's constitution, and I am equally glad to state that very few are troubled with secondary attacks; and I firmly believe, in those cases where it does happen, that it is in consequence of the mercury not being continued for a longer time. Sir Astley Cooper says Mr. Hunter's opinion was untenable, when he insists upon mercury being required for the cure of chancre, but afterwards goes on to state the practice in syphilis was much better twenty years before he wrote, merely from the circumstance of every patient undergoing a proper course of mercury. Afterwards, on the action of mercury, he says, "if a man be feeble or irritable, it then often induces sloughing and severe constitutional irritation," but strongly insists upon its administration in the secondary attack, *if* it has been omitted in the primary. Mr. Wallace has recommended mercury in some forms of phagadena, but Mr. S. Cooper, in his Dictionary, remarks—"I introduce Mr. Wallace's view of bringing the patient quickly under the influence of mercury, in certain states of phagadenic ulceration, not with any intention, however, of joining in its praise; for such is my conviction of the fatal mischief which I have repeatedly seen result from mercury in such cases, that I have long abandoned it, and find every reason to be satisfied with the results." Mr. Carmichael, and a host of other celebrated surgeons, agree with Mr. Cooper.

There can be no doubt that some cases of eruptive syphilitic disease will disappear without mercurial influence; but whenever it returns again, after omitting the medicines, I feel convinced no permanent cure can be effected without it. In the following case, mercury was exhibited at first; its action established and kept up, as I imagined, long enough to destroy any venereal virus remaining behind; then, again, in the form of Plummer's pill, after the secondary symptoms had set in. The disease still running on under its administration, I was induced to discontinue it, from a supposition that the hindrance to the patient's restoration was caused by it. After the lapse of some weeks, and every thing else had failed, I determined, as a last resource, in opposition to the general rule, to give him this medicine again, in the form of Donovan's solution. The following report will prove the result.

Case.—George Eggleton, ætat. 25, excavator, admitted into the infirmary, under my care, on the 11th of October, 1844, with a sore on prepuce, partaking of the venereal character. Has been standing about three weeks; nothing has been done for it. Robust appearance; good general health; accustomed to drink freely of beer. Ordered house diet; black wash to sore.

R. Pil. hydrarg. gr. iv, Pulv. opii. gr. ½ in pil., sumat ij omni mane et j nocte.

From this time to the 30th of November he gradually improved, and on that day left the infirmary as cured. His system was under the influence of mercury prior to, and about a fortnight after the sore had healed. Had just recovered from its effects when dismissed.

December 8.—Readmitted, with brownish spots sprinkled about the body, and an erythematous blush about midway on the upper part of left thigh, and just below the calf of right leg. Ordered nutritious diet; half a pint of porter.

R. Potass. iodid. gr. ij, Decoc. sarsæ ℥j, ter. die sum. Pil. Plummer. gr. v. omni nocte.

January 1, 1845.—The spots have disappeared. The cuticle, affected with erythematous blush at last report, became brown and scaly, falling off, and leaving complete rupial sores. The scalp is affected with sores of the same character. Poultice to sores, and occasionally bathed with a weak solution of nitric acid. Adde ferri ammon. tart. gr. x, ad haust.

February 24.—Ung. hydrarg. nit. oxyidi, to be applied to the sores.

March 1.—The sores have somewhat improved, and also his general health; but as it is very slow, he is advised to leave the infirmary, and try change of air. To continue the same directions.

8.—Again admitted. The sores increased in size; his health worse; loss of appetite; pulse weak, quick, and irritable; skin pale and bloodless. Omit. omnia. One pint of porter. Poultice and nitric acid wash.

R. Quinæ disulph. gr. ij, Acid. sulph. dil. *m*. viij, Tinc. aurant. ʒj, Aquæ ad ℥iss, ft. haust. sumat. ter. die. Bowels regulated by mild aperients.

March 29.—Sore on right leg three and a half inches in diameter; very unhealthy appearance; ragged edges; the soleus muscle and tendon sloughing; branch of external cutaneous nerve exposed, which causes considerable pain in outer part of instep; scalp considerably worse; eyelids very much swollen; loss of appetite. Continue porter and a glass of wine daily. Adde ferri ammon. tart. gr. x, ad haust.

April 10.—Gradually getting worse.

R. Solut. hydrarg. et arsenic. iodid. ʒiij, Ferri ammon. tart. ʒiij, Decoc. sarsæ Oj, ft. mist. sumat. coch. ij ter. die.

23.—Mouth tender; appetite improved; sores put on healthy action; general health improved. Omit solut. iodid. &c. ʒiss in mist.

May 17.—Slight tendency to relapse; gums scarcely tender. Auge solut. iodid. &c. ad ʒij in mist.

24.—From this time to the 5th of July the mercurial influence was gently kept up, and on that day he left the infirmary quite cured. He has remained well, also, since that time.

PROGRESS OF FRENCH SCIENCE.

(FROM OUR OWN CORRESPONDENT.)

Paris, August 22, 1845.

Academy of Medicine.—Sitting of August 19.—M. Caventou in the chair.

Corresponding Members.—A report was read by M. Girardin, relative to the nomination of French corresponding members. The reporter proposes that, before the close of the present year, twenty corresponding members be elected.—Unanimously agreed to.

Mineral Waters.—Exhibition of Arsenic in Ague.—After communicating to the meeting an elaborate report on the chemical composition of the ferruginous waters of Forges, M. Henry mentions the recent discovery of a sulphureous thermal spring in the province of Algeria. The waters contain minute quantity of arseniate of soda.

A discussion here ensued on the therapeutic action of arsenical preparations in intermittent fever. The following is an abstract of the debate:—M. Bally stated, as the result of long personal experience, that he had found arsenic of no decided advantage in the treatment of ague.—M. Desportes argued, it was not only powerless against the intermittent, but was prejudicial by its tendency to produce ascites and other abdominal complications.—Professor Piorry did not attribute the ascites observed to the arsenical preparations employed, but considered it as the natural result of the enlargement of the spleen, the constant companion of ague. He could not understand how the use of so dangerous a drug as arsenic was persisted in, when Science has demonstrated the perfect innocuity and heroic results of the exhibition of the salt of quinine.—M. Guéneau de Mussy brought forward the case of a woman who had been under his care at the Hotel Dieu. This person was affected with intercostal neuralgia and intermittent fever. Opium and various preparations of bark had been unsuccessfully exhibited, whereas she was cured within *three days* by the daily administration of a solution of one-twelfth of a grain of arsenious acid in half an ounce of water. A trifling relapse having occurred, one-twenty-fourth of a grain of the same substance completed the cure.

Academy of Sciences.—Sitting of August 18, 1845.—M. Elie de Beaumont in the chair.

Dangers attending the present Mode of Declaration of Births in France, by Dr. Loir.—"Declaration of the birth of a child shall be made within three days after accouchement, to the municipal officers of the district, to whom the infant shall be presented." Such is the enactment of the 53rd article of the Civil Code, and it is to the evil effects of the present execution of that law that Dr. Loir directs the attention of the Academy.

In all seasons the newly-born child *must* be carried to the mayoralty, and the fatal consequences of the exposure may be easily conceived. The statistical tables drawn up by Drs. Villermé and Milne Edwards demonstrate beyond refutation both the terrific mortality of infants and the influence of exposure to cold upon that mortality. Further inquiry shows that the deaths increase in number in direct ratio with the distance which separates the dwellings of parents from the offices of the municipality. The author concludes by proposing the following modification to the present mode of declaration, viz., "That in future the birth and sex of the child shall be ascertained at the mother's residence."

Plastic Operations on the Eyeball.—Dr. Plouviez, of Lille, made an interesting communication on this subject. The possibility of removing a portion of the cornea in cases where it has ceased to be transparent, and of substituting in its place the cornea of an animal, has been abundantly proved by recent experiments. The utility of the practice is not, however, so well demonstrated, inasmuch as Dr. P. himself acknowledges having performed the operation *very frequently* without *even once* obtaining perfect transparency of the engrafted membrane. In his *most successful* cases the borrowed cornea remained more or less opaline. Dr. P. mentions a young girl of twenty-three, who lost the use of her eyes, at the age of three, from small-pox. The opaque layers of the cornea were extracted, and in their place Dr. P. inserted the cornea of a young dog, who was killed for the purpose. Four stitches maintained the juxta-position, and adhesion was speedily obtained; but the only benefit derived from the operation was to permit the patient to distinguish day from night a little better than she did before.—Professor Flourens observed that M Feldmann, who has been pursuing for some time a series of experiments on this point of operative surgery, has reported more satisfactory results.

Ceratology.—M. I. Geoffroy St. Hilaire mentioned a singular anomaly in a ram lately presented to the Museum of Natural History. The male organs of generation are fully developed in the animal, but the teats, particularly on the right side, are enormously distended with milk. The secretion presents no remarkable difference from common goat's milk, and M. Chevreul has undertaken to examine further into its chemical composition.

Inhabitants of the Marquesas Islands.—Professor Dubreuil, of the Faculty of Montpellier, communicates to the Academy, through M. I. Geoffroy St. Hilaire, the results of his observations on the skulls of two natives of Nukaïva, in the Marquesas. These heads were discovered in a Morai, and brought to France by M. Commerins, a naval surgeon. One of these heads belonged to a man, the other to a young woman. A striking point in the former is the extreme length of the antero-posterior diameter, particularly when compared to the transverse measure of the skull. The face is rather long, the malar bones protrude, and the nasal arc elevated. The inferior maxilla is remarkable by the absence of its angle, the rami forming, as in the child, almost a straight line with the body of the bone. The female head is regular in shape, and even graceful in its contour—in neither does the facial angle approach 80°, a degree of aperture which M. Lebâtard attests he has commonly found in these latitudes. The examination of these two heads confirms Dr. Pritchard's remark on the resemblance between the islanders of the Southern Ocean and the Caucasian variety of the human family; they are also classed with the Caucasian race by Dr. Monro.

Anatomical Society; Meeting of August 22, 1845. Professor Cruveilhier in the chair.

A Romance of Real Life.—The following is not alone interesting by the singularity of the facts it reveals, but also by the results of the post-mortem examination of the body of the person to whom the history refers. An individual, of about fifty years of age, known in society in Paris under the name of Sir Edward Douglass, died on the 13th of August of acute peritonitis. He had married in France a lady, who subsequently eloped with a military officer; the deceased was said to be the natural son of a noble earl, who held a high office in the household of George III. On examination of the body, it was found to be that of a woman. The autopsy was performed, and the following alterations were discovered in the abdominal cavity:—The peritoneum was the seat of abundant serous liquid secretion, and a considerable quantity of sanguineous effusion, the result of acute disorder, existed in the abdomen. Two large fibrous tumours, attached to the margin of the uterus, were extracted with the womb, and presented to the Anatomical Society by Dr. Levaillant. The largest, situated on the left side of the uterus, with which it was connected by a pedicle inserted close to the left Fallopian duct, had acquired almost the size of the head of an adult, measuring from eight to nine inches in its length, and seven to eight in its breadth. The second tumour was rather more than half the size of the first; both offered the fibrous texture, and had become, in a great measure, the seat of bony deposit. The body of the uterus presented only one fibrous nucleus, and from the os uteri depended the pedicle of a mucous polypus, two inches and a half in length. The membrana hymenea was entire.

Syphilis of Deep-seated Organs.—M. Gabalda, interné of the Venereal Hospital (Midi), presented a remarkable case of tertiary disease of the cellular structure of the heart.

A man entered the hospital on the 10th of August labouring under advanced syphilitic symptoms. The patient had been previously affected with indurated chancre and secondary eruptions. He was, on entering the wards, found to be afflicted with cutaneous tubercles of the shoulder, and tertiary ulcerated sore of the penis, which presented to the unpractised eye the appearance of primary chancre; but its secretions were not inoculable. The ulcer had, however, given rise to lymphatic inflammation in its immediate vicinity, and a fistular passage had formed, extending to the pubes. One drachm of hydriodate of potash was exhibited daily, when on the 17th instant, the patient suddenly died.

Autopsy.—The internal organs were loaded with venous blood, but, except this congestive condition, no other cause of death was discovered. The heart was the seat of an uncommon alteration: it was evidently hypertrophied, and chronic endocarditis existed in the right ventricle only; but in the structure of the walls of the viscus, at least a dozen of those syphilitic tubercles, called by the French authors tumeurs gommeuses, had formed, and showed themselves at various degrees of evolution, from a slight ecchymotic hardness to a solid induration, and incipient ramollissement. An analogous tumour was detected in the basis of the left lung. The history of these tumours, particularly in the lungs, is practically most interesting. They give rise to all the physical signs of tubercular consumption. Their presence in the organ causes dullness on percussion, and diminution of the respiratory murmur. When they soften and ulcerate, the broncho-cavernous respiration and pectoriloquy are present. The constitution of the patient giving way at the same time, leads to the almost inevitable, but erroneous conclusion, that he is labouring under the fatal influence of phthisis; and the diagnosis can only be assisted by an accurate appreciation of the history of the case and a correct knowledge of the connection of the syphilitic symptoms with each other. The immediate influence of hydriodate of potash in the cure of tertiary syphilis affords a fair chance of recovery, if no accidental complaint interferes with the natural progress of the case. Instances of cure, referable to this form of complaint, were published by Dr. Monk in 1841 (see *Medical Gazette*), and his cases, as well as Dr. Ricord's, may perhaps be considered analogous to those which Morton denominated "syphilitic phthisis."

Absence of External Organs of Generation—Imperforate Anus—Dissections; by Dr. Jamain.—On the 19th instant a child was born who lived only a few minutes. The body was reported by the midwife to be that of a female child, but further inquiry showed that the external organs of generation were absent. The body was obtained for Dupuytren's museum by Dr. Jamain, who brought it to the society. The anus is imperforate: in front of the coccyx lies a scar, which seems to cover a bifurcation of the sacrum. The skin of the perinæum is smooth, and presents on the left of the mesial line *one* thin and empty fold; the cutaneous surface being removed, is found to cover only a large quantity of cellular tissue. The disposition of the abdominal viscera is very irregular. The *rectum*, distended by meconium to the size of a hen's egg, is terminated by a cul de sac, and floats in the pelvis, attached to the sacrum by a loose meso rectum. The *renal* capsules are enormous: the *kidneys* are absent; *the right testis*, the larger of the two, lies on the sacro-iliac symphysis, the left on the side of the second lumbar vertebra: each is furnished with its gubernaculum. The *ureters* are absent. The pelvis is occupied by a small body supposed to be the *bladder*. The dissection to be continued.

DAN. M'CARTHY, D.M.P.
President of the Parisian Medical Society, late Interné of the Hospitals of Paris.

PROGRESS OF ENGLISH, ITALIAN, AND AMERICAN MEDICAL SCIENCE.

[The following are the only articles of interest to the profession in two numbers of the *Lancet*.]

GANGRENA SENILIS.—Mr. Taylor recommends, in cases of gangrena senilis, wrapping up the diseased part in lamb's-wool, and narrates a case in which it appeared to be beneficial. He considers that, in treating this disease, the main indication should be to preserve the capillary circulation of the part in sufficient activity. Constitutional treatment is also to be employed consentaneously.

DIFFICULT LABOUR.—Dr. J. Hall Davis was called in consultation to a case of protracted labour in a female thirty-eight years of age, where the head of the child was fairly wedged in the brim of the pelvis, and the bladder much distended with water. The contents of the latter were drawn off by means of the gum-elastic male catheter, and free bleeding was prescribed; after which, the woman was delivered by embryotomy, the osteotomist being used. The child had been dead several hours. The woman recovered. Dr. J. Hall Davis was also consulted in a case of difficult labour occurring in a primipara, thirty-six years of age, in whom the dilatation of the os uteri had gone on rightly, with the exception of a small portion in front, which continued rigid. The head was arrested at the brim of the pelvis. As the case was complicated with very severe pain, different from, and occasional to, the pains of labour, Dr. J. H. Davis decided on abstracting blood freely, which was done with relief. A few hours later, the rigid portion of the os uteri being obliterated, the long forceps were applied, and a dead child born. The mother did well.

POISONING BY OIL OF BITTER ALMONDS.—Dr. Letheby records a case of poisoning by the oil of bitter almonds, in which the following post-mortem appearances were met with:—The face was still placid, but pale; the eyes half open; a little foam adhered to the mouth, and it had the smell of bitter almonds. The dependent parts of the body were livid; the lungs were congested, and the right side of the heart was gorged with dark fluid blood; the abdominal cavity gave out the odour of the poison, but this was not noticed in any other part of the body; the stomach contained twelve ounces and a half of a pulpy, semi-fluid matter, in process of digestion; it had a powerful odour of bitter almonds. The internal coat of the stomach was generally pale, but here and there, especially along the greater curvature, some red petechial patches were observed. On subjecting the fluid to distillation, and saturating with nitrate of silver, Dr. Letheby procured one grain of cyanide of silver, indicating about two-tenths of a grain of pure hydrocyanic acid, a quantity contained in ten drops of the dilute acid of the Pharmacopœia; a further distillation enabled him to collect the volatile oil of the bitter almonds, freed, however, from prussic acid. The points of medical interest were, that the child was not convulsed, that he did not speak after he was seen, nor was there any scream or evacuation of the stomach, the bladder, or the rectum. He appeared to die from a paralysis of the respiratory muscles, the breathing becoming slower and slower.

FEVER, WITH SUPPURATION OF THE SPLEEN.—Mr. Chiappini was called to a case of fever, of four days' duration, in which the symptoms seemed principally to indicate head affection. The man was bled several times, both locally and generally; had saline and purgative medicines, and was afterwards placed under the influence of mercury. On the eighth day evidences of splenitis, with typhoid depression, showed themselves, followed by the usual indications of suppuration, and death on the fifteenth day. The examination of the body was made the next day. On opening the cavity of the abdomen an effusion of dreadfully offensive dirty-looking fluid was found, to the amount of a couple of pints. The upper part of the gastro-colic and the splenic omentum was violently inflamed; so was the peritoneal surface of the diaphragm on its left side, to which large shreds of coagulable lymph were adherent. The spleen was firmly adherent to the omentum, and to the peritoneal surface of the diaphragm (which was very much indented by it), to the cardiac extremity of the stomach, and to the posterior surface of the left lobe of the liver, corresponding to the cardiac orifice of the stomach. The capsule of the spleen was very much thickened and disorganised, and the organ itself was enlarged to at least ten times its natural size. On its convex surface, towards the ribs, were two large ragged-looking cavities containing a purulent sanies, and running into each other; in the upper part of its concave surface there was also a very large abscess, besides several smaller ones in the lower portion of the organ. The upper part of the parenchyma was completely soft and pulpy. The stomach and bowels were healthy. The liver and left kidney were sound, but in the tubular substance of the right kidney, and in the pancreas, there was purulent infiltration to the extent of about three drachms in each. There was not the slightest trace of any inflammatory action having existed in either of these organs, so that the pus found in them must have been a secondary deposit of the morbid fluid absorbed into and circulating with the blood. The peritonitis appeared to have been perfectly circumscribed, from the transparency and natural appearance of the membrane in the right hypochondrium and lower part of the abdomen. On opening the cavity of the chest, an effusion of plastic lymph was found along the sides of the mediastinum. Between four and five ounces of limpid fluid were effused into the pericardium: the upper lobe of the right lung was in a state of sanguineous infiltration; the middle and lower lobes were black and putrid, possessing a highly fetid gangrenous smell; their whole substance seemed to be

broken down into a putrilage, similar in appearance to that seen lining the mucous membrane of the uterus in some cases of puerperal fever. Both lobes of the left lung were in a similar state, though not quite to the same extent. In the upper part of the left side of the chest there were extensive adhesions of the pleuræ, and the lower part of the cavity was perfectly filled with a muddy sanies, evidently pleuritic effusion, mixed with the putrilage from the lungs. On the right side, the pleuræ were also violently inflamed, with extensive effusion of thick flocculi of coagulable lymph.

UNUSUAL PHENOMENA OBSERVED DURING AN EPILEPTIC FIT.—Mr. Tripe records the case of a female, twenty-two years of age, of plethoric habit, subject to epilepsy for years, and formerly accustomed to drink freely, to whom he was summoned while she was labouring under a very severe attack of epileptiform convulsions, which were ever and anon succeeded by coma. Venesection was practised, but very little blood was obtained. The temporal artery was then opened, from which flowed, with a per saltum motion, a stream of arterial-coloured blood, but in a short time another fit supervened, when some unexpected phenomena presented themselves. On the first occurrence of the convulsions, the stream issued more forcibly from the orifice, but gradually became altered both in colour and motion, the arterial tint slowly changing to a dark venous, and the leaping motion to a continuous stream, so that the blood appeared as if flowing from a vein, and with increased rapidity. This lasted during the height of the paroxysm (about one minute and a half), after which it subsided with the convulsive movements. The pulse during the comatose state was weak and fluttering, but when the struggling commenced it rose in force and fulness; and as they increased it gradually became imperceptible, and as they diminished, so it returned to the state first described. The action of the heart, at first irregular, unequal, and laboured, became more powerful when the convulsions first occurred, but lessened as they increased, though it still continued whilst the blood was flowing in a continuous stream from the temporal artery. The respiratory movements also ceased during the greater part of the paroxysm (about two minutes and a half), the chest being fixed, the diaphragm motionless, and the glottis closed. During the flow of the blood, which lasted nearly twenty minutes, three fits occurred, each of which was attended by similar phenomena. The patient recovered.

STRANGULATED INGUINAL HERNIA.—Mr. Bottomley describes a case of strangulated inguinal hernia, which he operated successfully, although the patient was at the time apparently nearly dying.

ABDOMINAL PULSATION.—Mr. Wolff describes a case of obscure abdominal pulsation, evidently of a chloroto-anemic origin, which was supposed by a physician to be produced by aneurism. It was cured by tonics.

IMPERFORATE VAGINA.—Mr. Vawdrey was consulted in a case presenting the usual symptoms of retention of the menses, caused by an imperforate vagina. On examination this was found to be the case, and an incision made in the obstructing membrane was followed by the discharge of about two quarts of a black-looking sanguineous fluid, not mixed with coagula, and free from any disagreeable odour. The patient went on well till the eighth day, when symptoms closely resembling puerperal peritonitis came on, but were speedily checked by bleeding, free leeching, and the internal exhibition of calomel and opium, pushed so as to affect the gums.

APPARENT OCCLUSION OF THE VAGINA.—Dr. Carter narrates a case of pregnancy in a woman who had been previously delivered by instruments, and undergone extensive laceration of the perineum, the vagina and rectum having been made one sulcus. Following the direction of the vagina, about three inches from its orifice, the finger was arrested in a pointed cul de sac; withdrawn about an inch and a half, and directed backwards, it entered the rectum, the anterior edge of which was here sharp and thin, but surrounded a little higher up by distinct muscular fibres, which, when irritated by the finger, contracted, supplying, in some measure, the place of the sphincter. The os uteri could not be detected either by the rectum or through the walls of the cul de sac. A very careful examination was now made with a silver catheter by Dr. C., to discover, if possible, any foramen or canal which the finger could not detect, but none existed. During a pain he distinctly ascertained the presence of fluid behind the fleshy septum, and cautiously introduced a bistoury, which immediately produced a gush of liquor amnii. A couple of fingers were then introduced into the cavity of the uterus, and the head of the child was found presenting, but situated above the brim of the pelvis, which was unusually narrow both in its lateral and antero-posterior diameters. The head afterwards descended lower into the pelvis, but was tightly encircled by the rigid os uteri and remains of the vagina, which tension could only be relieved by several slight incisions with a bistoury around the circumference. Anteriorly, the head was impeded by a fleshy mass, which proved to be the bladder, displaced and thrown forwards in the former labour. The woman was delivered with the forceps, and the placenta extracted by manual interference.

ORCHITIS.—A case of acute orchitis is reported from the Manchester Infirmary, in treating which strips of adhesive plaster were bound firmly around the testicle, as is practised by some surgeons in cases of chronic enlargement. The symptoms were much aggravated in consequence, and the strapping was necessarily removed. The reporter says, "on a superficial view of the case, it will be seen that the pressure had been the cause of the augmentation of pain and the violation (?) of the symptoms"—thus constituting, in his wisdom, a new crime for our legislators to condemn.

USE OF NITRIC ACID.—Mr. Wilkinson employs nitric acid internally as a tonic and corrective in many cases, and appears to have derived advantage from its use. He exhibits it in larger doses than are generally given.

ULCERATION OF THE CERVIX UTERI FOLLOWING THE REMOVAL OF UTERINE POLYPUS.—Dr. J. H. Bennett narrates two cases in which ulceration of the cervix uteri accompanied or followed the removal of a polypus from the womb, and required appropriate treatment for its cure. He advises, therefore, that in every case, when a polypus has been removed, the speculum should be used a few days afterwards, to ascertain the state of the cervix uteri.

SPONTANEOUS GANGRENE.—Mr. Bottomley describes a case of spontaneous gangrene of the foot, occurring in a woman who was more than half-starved, in which he performed amputation above the knee. The patient recovered.

PURPURA HEMORRHAGICA.—Dr. Hogg attended a maiden lady, labouring under a very severe attack of this disease, in treating which the acetate of lead seemed to be the most effectual remedy. Towards the end of the case excessive hemoptysis set in, and was relieved by venesection. The tinnitus aurium, which also supervened, is attributed by Dr. Hogg to the action of the lead, but was more probably produced by the very great loss of blood. Dr. Hogg would have done well to have had the blood examined chemically and microscopically; there cannot be a doubt but that it was deteriorated.

FOREIGN BODY IN THE RIGHT BRONCHUS.—Dr. Sheppard was called to an aged gentleman, who had gone to sleep with a piece of ginger in his mouth, which had slipped into the trachea, and descended into the bronchus. Inflammation set in, as evidenced by the symptoms, and the patient died the next day. On examining the body, the lungs were found inflamed, and loaded with semi-purulent mucus. The ginger lay at the upper part of the right bronchus, near the bifurcation. It was much swollen and soft, and measured an inch and a quarter in length, half an inch across at its widest part, and about three-eighths at its narrowest, which was also its middle.

AMPUTATION AT THE KNEE.—A case of disease of the knee-joint is reported from King's College Hospital, in which Mr. Fergusson amputated in the following manner:—The operator, standing on the outside of the limb, placed the heel of a common flap amputating-knife upon the skin on the inner side of the joint, immediately over the condyle, and made a semi-lunar sweep across the front, extending below the apex of the patella until the point of the blade was opposite the external hamstring, when it was thrust straight across the limb through the popliteal space, and made to appear at the part where the incision in front had commenced; the blade was then carried downwards, so as to form a large flap, from the muscles on the calf of the leg; the skin in front was now drawn above the level of the upper margin of the patella; the quadriceps extensor was next divided; a circular sweep was then made round the bone immediately above the condyles, and the saw used to complete the separation of the limb. A tourniquet had been applied previously to the operation, and little blood was lost during the incisions; a good deal was lost, however, before all the bleeding vessels could be secured, and this seemed principally on account of the difficulty of applying a ligature to the popliteal artery, which, owing to the thickened and hardened condition of the tissues around it, could not be seized and drawn out with the forceps in the ordinary manner. At last, after the application of several ligatures, the bleeding here seemed arrested, and the other smaller vessels were next secured; the large posterior flap was then brought forward, and a few stitches were employed to hold the surfaces and margins together. The patient, at the date of the report, was doing well. In some clinical remarks, which he made on this case, Mr. Fergusson stated that he had been induced to select the site of this operation chiefly by the published recommendation of Mr. Syme, of Edinburgh, in its favour. That gentleman had performed it on several occasions, and his reports were so favourable, and the proceeding at the same time offered so many seeming advantages, that he deemed the practice well worthy of imitation. The operation at the knee-joint, although successful occasionally, had hitherto proved so unsatisfactory, that few surgeons in this country were inclined to perform it; but this proceeding, it would be remarked, was not actually in the joint, for the saw was carried through the condyles of the femur above, though close to, the articular surfaces, the patella being removed with the lower part of the limb. Whether the narrower extent of bone thus left would be accompanied with less hazard to the patient than when the condyles were allowed to remain, would have to be proved by the results; but it would at once appear that the end of the femur could be more readily covered in the one case than in the other. Mr. Syme favoured this operation chiefly on the supposition that in consequence of the femur being cut across so close to the epiphyses, there would be less risk of inflammation of the medullary canal, and consequent necrosis of the bone; and as it was well known that this result (necrosis) was more likely to follow an injury of the hard portion of the shaft than of its spongy extremity, there was on this account great inducement to apply the saw thus low down. But there were other good reasons for choosing such an operation, and not the least of these was, that amputation for certain injuries and diseases in the leg, necessitating the section above the knee, might nevertheless be done so low down—so far from the trunk, comparatively, as to lessen the risk on that account as well; for it was a maxim, that the danger of amputations increased as they approached the trunk. Hitherto, when an operation of this kind had been done above the knee, the knife had been so applied as to reserve all the soft parts to form the stump from the thigh alone; but here it would be remarked, that the flap for a stump of the thigh had been taken from the leg, where, in such an instance as that which was at present under notice, there was ample material for making a flap of any extent that might have seemed desirable. In accidents, and in all diseases of the leg, when amputation in the thigh was requisite, it was not improbable that such a proceeding as this might prove a valuable acquisition to surgery; and even in most of the diseases of the knee-joint necessitating this last resource, it might possibly be proved to be a preferable proceeding to the section higher up. The swelling of a joint, wherein the articular surfaces and ends were in a state of ulceration and caries, had been proved to depend entirely on these diseased conditions, as had been evinced by excision of such parts, and it was a doctrine of modern surgery, that in removing caries there was no necessity for reaching beyond the actual seat of the disease. There were many examples of incurable affection of the knee-joint which might possibly be best treated by such a mode as had been followed in this in-

stance. One objection to the operation was apparent at the time it was done, and that was the difficulty of securing the popliteal artery. The vessel was so surrounded by effused lymph, and condensed cellular tissue, that he had to slit up the tissues ere he could seize the vessel with the forceps, and even then, it was with no inconsiderable trouble that he could get a ligature placed so as to stop the flow of blood. That had been done, however, after several unsuccessful attempts, and the pupils had all had the opportunity of seeing how completely the swelling of the soft parts had subsided since the removal of the source of irritation. The stump was now an excellent one for its age, and the results in this case had been such as to encourage him to follow a similar proceeding in the next eligible case that might fall under his notice.

Nævus Maternus.—Mr. Davis treats nævus maternus by making several small punctures in the tumour, and injecting a saturated solution of alum by means of Anel's syringe, until the nævus becomes somewhat hard and swollen. No other treatment is required; the inflammation caused by the injection gradually subsides, and the nævus disappears in the course of time.

Dislocation of the Astragalus.—At a meeting of the Newton branch of the Provincial Medical Association, Mr. Jordan mentioned the case of a man who was admitted under him at the infirmary, with luxated astragalus, where the reduction was more easily accomplished than is usual in such accidents. The individual, who was about forty years of age, fell from a height of two yards, not knowing upon which part of his foot he alighted. On his admission, the lower part of the fibula was found projecting, and on its anterior and inner part was a large hard projection; the foot was turned downwards and inwards. Three grains of tartarised antimony were given to the man, and the pulltes applied above the knee. A strong man passed one hand round the os calcis and the other on the fore-part of the foot, and continued steadily extending it for some time. Mr. Jordan then passed the two forefingers of each hand round the ankle, while the thumbs rested upon the projecting astragalus, pressing firmly downwards. After ten minutes' extension, Dr. Ainsworth passed his hand under the os calcis, the astragalus slipped into its place, and the man recovered without an unfavourable symptom.

Hæmoptysis in a Child.—Dr. Walker describes, in the *Provincial Medical Journal*, a cause of hæmoptysis, which occurred in a scrofulous child, four years of age, and terminated fatally.

Chronic Gastritis and Perforation of the Stomach.—In the *Provincial Medical Journal*, Mr. Collyns narrates the case of a man of intemperate habits, who, after having for some time suffered from chronic gastritis, was suddenly seized with severe pain in the left hypochondrium, which extended over the abdomen, and became more and more intense. The man died sixteen hours after the attack. The abdomen was examined about six hours after death; it presented all the appearances of the most acute recent peritonitis. It contained rather more than three quarts of a turbid yellowish fluid, with flakes of recent lymph floating in it; coagulable lymph was also deposited on the peritoneal surfaces of the various abdominal viscera, while here and there, on different points of the intestines, was a thin layer of pus. In the stomach, a small circular aperture, about one-third of an inch in diameter, was seen on its anterior surface, about two inches from the cardiac orifice; and just below the smaller curvature, and around this point, the appearances were more indicative of intense peritoneal inflammation than elsewhere, several firm layers of coagulable lymph being deposited on the coats of this organ, which could be stripped off one from the other with the finger nail. On opening the stomach, which was empty, a large surface of ulceration, the size of a crown-piece, was found in the mucous coat, with considerable heaping up around it of submucous tissue, causing the appearance from within outwards of a funnel-shaped cavity, more than an inch in depth, at the bottom of which was the small circular opening through the peritoneum. The appearances of chronic inflammation around the circle of ulceration were very strongly marked, the mucous membrane being thickened and injected for a considerable space around the spot, where it had become destroyed by the ulceration. On looking further, it was apparent that another and previous attempt at perforation had been made at the posterior wall of the stomach, its coats having been eaten through in the same manner as in the anterior wall; the pancreas, however, had blocked up the opening, the ulceration having extended slightly into the surface of this viscus, at the point where it had become adherent. The general structure of the pancreas was thicker and harder than natural, but did not give any idea of scirrhous disease, nor did the diseased appearance of the stomach present the characters of scirrhus, but rather of simple chronic inflammation, with submucous thickening. The pyloric half of the organ, the pylorus itself, and the duodenum, were perfecty healthy; the liver was pale, smooth, and reduced in size; the spleen was small but healthy.

Poisoning by Prussic Acid.—Mr. Nunneley, in a recent number of the *Provincial Medical Journal*, has recorded a case of poisoning by prussic acid, in which the patient survived the ingestion of the poison nearly three quarters of an hour. The cold affusion, ammonia and chlorine, and the mustard pediluvium, were employed, but unavailingly. In a succeeding number of the same journal, Mr. Nunneley narrates another case of poisoning by prussic acid; forty minims of the acid were taken, but by prompt aid the man's life was saved. The cold affusion, ammonia, a sulphate of zinc emetic, and bleeding, constitued the plan of treatment which was adopted, and successfully, by Mr. Bishop, the practitioner who was first sent for to see the man.

Mean Composition of the Blood in the Phlegmasiæ, according to M. Becquerel:—

	Men.	Women.
Density of blood deprived of its fibrine	1056·3	1054·5
——— of serum	1027·	1026·8
Water	791·5	801·
Globules	128·	118·6
Albumen	66·	65·8
Fibrine	5·8	5·7
Extractive matters and free salts	7·	7·2
Fatty matters	1·742	1·669
Seroline	0·020	0·021
Phosphorated matter	0·602	0·601
Cholesterine	0·136	0·130
Soap	0·984	0·914
In 1000 grammes of Calcined Blood.		
Chloride of sodium	3·1	3·0
Soluble salts	2·4	2·7
Phosphates	8·448	0·344
Iron	0·490	0·480

ON THE DIAGNOSIS, PARASITIC GROWTH, TREATMENT, &c. OF PORRIGO, OR SCALD HEAD.

By D. J. Corrigan, Esq., M.D., Physician to the Whitworth and Hardwicke Hospitals.

In a paper on this subject, appearing in the *Hospital Gazette*, Dr. Corrigan first notices the confusion arising from the varieties in description and treatment applied to the affection; the mild and intractable forms of disease of the scalp being confounded together, from want of accuracy in diagnosis; and the difference of nomenclature of one and the same disease, adopted by French and English writers, creating so great a perplexity in this class of affections, that any one of them may be spoken of by any two writers, or two persons in conversation, each person having at the moment an entirely different disease in view.

The author's leading object is, he observes, to induce us to look on the disease as possessing a single and fixed character, incapable of subdivisions, which are as useless as they are unfounded. Whether the affection attacks a limb, or appears as a solitary areola on the scalp, or covers its whole surface, or involves a large portion of the surface of the body, its characters are unvarying. The modifications assumed to exist by Bateman, and named by him porrigo larvalis, porrigo granulata, and porrigo scutulata, are all presented by impetigo while porrigo decalvans and furfura are not pustular diseases at all. We have then remaining only the porrigo lupinosa of Bateman, or the genuine scall, possessing characters so distinct, that, Dr. Corrigan observes, it is matter of surprise how it could ever have been confounded with any other disease. In order to distinguish the peculiar incrustation of porrigo from the scales of eczyma, which sometimes accumulate to such a degree as to resemble the scab of porrigo—the difficulty being occasionally increased, too, by the coexistence of those two diseases—the author recommends the head to be shaved and poulticed until the entire scab disappears; the scalp to be then washed clean with soap and water, so as to present a clear, smooth, red surface; upon which, within some days, a few, often not more than three or four, minute particles appear, not prominent, but like dots of transparent matter imbedded in its surface; a period of from seven to fourteen days will be sufficient to trace the progress of their growth; in twenty-four hours after their first appearance they become solid, depressed in the centre, and of a pale yellow or sulphur colour, having frequently a hair in the centre, presenting the cup-shaped surface of the peculiar pustule or favus of porrigo, the contained matter being so dry as to be almost friable. The growth of this cheesy, friable substance, now goes on very rapidly, the colour changing to a grayish-white, and at length accumulates to such a degree as to resemble lumps of mortar sticking on the head, with a peculiar odour resembling that from urine; but the singularity of its development is, that if a portion of the scab be removed, by slight traction or poultices, there is merely the red surface beneath,—no ulceration of the skin, no formation of purulent matter, which, in drying, might form the thick scabs lying on the surface—thus evincing a mode of growth in the incrustation itself entirely independent of any ulcerative process or suppuration in the skin. If an eczymatous scalp be similarly treated, the scalls are observed to form gradually on the inflamed skin, the peculiar favi of porrigo never appearing; or, if the disease be impetigo, the cleared surface is seen to pour out, like an oozing, a semi-transparent, honey-coloured secretion, which soon dries into a soft, greenish-coloured scab; but here, as in eczyma, and all the other diseases of the scalp, the peculiar pustule of porrigo, running through the above-described stages, is absent.

We have, however, Dr. Corrigan observes, a still more accurate means of diagnosis in the ordinary achromatic microscope for medical purposes, with a magnifying power of 300 diameters, which furnishes a means of instantaneously and with certainty distinguishing the disease under consideration. Three drawings were made at the moment of examination by the microscope, by his friend, and clinical clerk, resident at the hospital, Mr. Rambaut, the first being a representation of the pus globules in recent matter taken from a case of impetigo, and presenting the same appearance as those of ordinary pus.

The second represents a portion of the dried scab of impetigo, which, being moistened with a little water, and placed under the microscope, exhibited the appearance of an amorphous mass, the portions comprising it being somewhat like the scabs of the epidermis or mucous membrane. The third drawing exhibits the appearances observed in a portion of the moistened scab of genuine porrigo—appearances so closely resembling those of a cryptogamic plant, that any one who has seen them, Dr. Corrigan observes, cannot hesitate to consider porrigo as consisting in the growth of fungi in the human skin. To Dr. Bennet, of Edinburgh, who has published perfect drawings of this parasitical vegetable, in a paper contained among the transactions of the Edinburgh Royal Society, he states that he is indebted for the first demonstration of this singular fact, the discovery itself being due to Ehrenberg, of Vienna.

Dr. Bennet has discovered the cryptogamic plant of porrigo in the common house mouse; and this, Dr. Corrigan observes, may have more to do with the peculiar odour of the disease than might at present be suspected, and may serve to illustrate some intimate connection between man and the lower animals in the propagation of disease. The nature of porrigo, he adds, may now, perhaps, serve to explain its peculiarity of growth accumulating

rapidly upon the surface, independent of any secretion of pus to form the mass of the scabs; the growth of a single favus of porrigo, too, if observed, will be seen to take place at the circumference, its height being acquired at the edges, all round the circumference, while it remains hollow in the centre, this being in accordance with what is observed in many cryptogamous plants, which, having exhausted their pabulum in the centre, continue to grow out in a circle. Dr. Corrigan concludes by observing that the disease, as he has always seen it, is chronic, and is not confined exclusively to the scalp, having observed it now and then on almost all parts of the body, in some cases consisting of only two or three favi on the back of the neck.

He does not believe it to be contagious, and is strengthed in this opinion by the failure of attempts made by Bennet and others to inoculate with the disease; its non-contagious nature, he observes, contrasts strongly with impetigo, which spreads so rapidly among children.

As evidence of the rarity of the disease in Ireland, he observes that all the cases he has ever seen would hardly amount to 30, an additional contrast to impetigo, eczyma, pityriasis, &c. of the scalp, which are so common. He has never seen it in private practice, or in respectable life, and suggests the possibility of its being propagated from an inferior animal, like cow-pox, the odour of this mouse (a well-marked diagnostic sign) being so strong in the disease as to strengthen the supposition of its being derived from that animal, on which Dr. Bennet has discovered the same parasitic plant as in porrigo; poverty or sickliness reducing the living body to a state fit to constitute a nidus for a parasitic plant.

Reflecting on the nature of the disease suggested to Dr. Corrigan the employment of an ointment composed of five or ten grains of oxymuriate of mercury to an ounce of ungt. cetacei, a remedy on which he places much reliance; in the latter proportion it sometimes gives pain. A small portion of the ointment is rubbed on the affected part every day, and it has not produced salivation in any instance. The author records three cases in which the remedy was attended with marked success, but in one only, he observes, has the relief experienced lasted sufficiently long to admit of its being considered a cure; the disease has again and again disappeared after having been repeatedly subjected to various modes of treatment by Dr. Corrigan, and by gentlemen at other hospitals, but continued to reappear until put under the use of the foregoing ointment, in February last, since when the patient, who lives in the neighbourhood of Whitworth Hospital, has been entirely free from the disease.

REVIEWS.

Lectures on Subjects connected with Clinical Medicine, comprising Diseases of the Heart. By P. M. Latham, M. D., Fellow of the Royal College of Physicians, Physician Extraordinary to the Queen, and late Physician to St. Bartholomew's Hospital. In 2 vols. London: Longman and Co. 1845.

(Continued from page 412.)

The abnormal sounds of the heart, to all of which Dr Latham applies the name of "murmur," and, inasmuch as they are always produced by conditions found either within the cavities or upon the external surface of the heart, that is, either inside or outside of it, distinguishes as endocardial or exocardial, are treated of in the second and third lectures.

The distinction is first drawn between these two kinds of murmurs, or, rather, some brief but excellent indications are pointed out, by which a murmur may be recognised as either endocardial or exocardial, although, at the same time, great and necessary stress is laid upon the fact, that every man must become acquainted with these murmurs by the teaching of his own ear. The endocardial murmur is not only different in kind from the natural sounds of the heart, but it takes their place, and is heard in their stead. It comes exactly where the first, or second, or both sounds should be. It keeps strict time with the systole or diastole of the heart, or with both. It has, also, more frequently a single sound, but sometimes it is double; moreover, it is commonly more inward and deeper, and further from the ear, and conveys to the ear the idea of blowing. The exocardial murmur, on the other hand, does not take the place of the natural sounds of the heart; in proportion as it is louder, it obscures or overpowers them, but still they are apt to reach the ear through the exocardial murmur, and, when they do not, it is because they are imperceptible under the circumstances, not because they cease to exist. The exocardial murmur is rarely less than a double sound, and is more outward, nearer to the surface, and closer to the ear. It gives the idea of two bodies moving in contact with each other.

The endocardial murmur results principally and most frequently from unusual vibrations, communicated to the particles of the blood by obstacles which it encounters in its passage through the heart; which obstacles are seated, generally, in certain portions of the endocardial membrane rendered unsound by disease, to wit, where it is of a denser structure, either in itself or from an admixture of other structures, whether cellular or fibrous, with its own.

"This character of a denser texture belongs to it where it forms the tough white circles which surround the apertures of communication between the auricles and ventricles; also where it is reflected upon itself, and forms the loose duplicatures of membrane which are given off, as it were from the internal surface of the heart, either at the fibrous circles intermediate between the auricles and ventricles constituting the tricuspid and mitral valves, or at the commencement of the pulmonary artery and the aorta, constituting the semilunar valves.

"It is remarkable how curiously disease is apt to limit itself to the spaces just pointed out. Of the fibrous circle between the auricle and ventricle, of the valves which originate from it, and of the tendinous cords which connect the valves with the carneæ columnæ, there will not perhaps be the smallest space free from disease; but the disease will abruptly stop where the tendinous cords cease and the carneæ columnæ begin. The membrane, however, where it covers the fleshy columns of the heart, is not exempt from the possibility of disease; but, when disease actually affects it, it has seldom originated there, but has generally spread from other parts of the same membrane, although (as we have just remarked) it is apt to stop short before it reaches it."

At the same time, it is possible for the blood spontaneously, or, at least, independent of any known obstacle which it encounters, to allow vibrations among its particles, from which the true endocardial murmur may arise. Cases showing the fact are not of unfrequent occurrence. Endocardial murmurs, caused, as has been already implied, by disease of the valves, are produced either by the obstacle being offered to the direct passage of the blood through the orifice at which the obstruction exists, or else by the regurgitation of the blood through the orifice where the valve is diseasedly deficient, or they may be produced by both causes at once. The facts which led to the belief in the doctrine of the regurgitation of the blood being productive of endocardial murmurs—a cause which was not admitted by Laennec, who held the erroneous doctrine that each cavity of the heart was instrumental, by its contractions, in producing the murmur which proceeded from the injured valve immediately beyond itself, and, consequently, referred the murmur which existed when the aortic valve was diseased, to the systole of the left ventricle forcing the blood through the narrowed aortic orifice, and, when the mitral valve was diseased, to the systole of the left auricle forcing the blood through the narrowed auriculo-ventricular orifice—are as follow:—

"In numerous well-watched cases, where a single murmur, constantly and uniformly coincident with *the systole* of the heart, had been heard during life, the valve at the entrance of the aorta, and this valve only, was found diseased after death. Here the murmur marked the time of the blood passing *onwards* from the ventricle into the aorta, through an orifice only half open, which should be open altogether. This was no murmur of regurgitation.

"Again, in numerous cases, where a single murmur had been heard during life, but constantly and uniformly coincident with the *diastole* and not with the systole of the heart, still this same valve at the entrance of the aorta, and this valve only, was found diseased after death. Here the murmur marked the time of the blood recoiling *backwards* from the aorta towards the ventricle, and partially re-entering it through an orifice only half-closed, which should be closed altogether. This was the genuine murmur of regurgitation.

"Again, in numerous cases, where two murmurs had been heard during life, one coincident with the systole, the other with the diastole of the heart, still this valve at the entrance of the aorta, and this valve only, was found diseased after death. Of these two murmurs, proceeding from one and the same orifice, the latter was the genuine murmur of regurgitation, and not the former.

"It appeared, then, that the aortic valve, in its states of disease, was capable of becoming the seat of two murmurs, one regurgitating and the other not; of either separately in different cases, or of both together in one and the same case.

"Yet, again, in numerous cases, where a single murmur, constantly and uniformly coincident with the systole of the heart, had been heard during life, the mitral valve, and it alone, was found diseased after death, while the aortic valve was perfectly healthy.

"But how could this be explained? In its natural course it is during the diastole, that the blood passes through the orifice guarded by the mitral valve from the auricle into the ventricle. Here, however, the mitral valve being diseased, the murmur does not mark the time of the blood passing *into* the ventricle by the mitral orifice, but the time of its passing *from* the ventricle by the aortic orifice; yet there was no disease of the aortic valve to cause it. The only material thing, capable of producing it, was still the diseased mitral valve. But how could this produce it? Even by admitting the regurgitation of blood back into the auricle. And the very point of time, at which the murmur takes place, marks this for the cause, and this for the manner of its production.

"The same systole of the ventricle, which carries the blood forwards into the aorta, without impediment and without a murmur, where there is no disease, throws it back partially, and with a murmur, into the auricle through the half-closed mitral orifice, which now admits its regurgitation.

"It has been said that the aortic orifice of the heart may be the seat of two murmurs, in consequence of disease of its valve; one systolic, from the blood in its direct course, the other diastolic, from the blood during regurgitation. Either murmur may occur alone in different cases, or both may occur together in the same case. But it would almost seem that the mitral orifice could be the seat of only one murmur, and that murmur the systolic. Remember, the systolic murmur proceeding from the mitral valve always implies regurgitation.

"Yet the condition of disease in the mitral valve is often found to be such as must have raised certain impediment to the passage of blood from the auricle into the ventricle. Why, then, is the murmur, which would indicate such impediment, and which would be coincident with the diastole of the heart, a thing not found in practice, when the mitral valve alone is diseased?

"It is probable that, as in health, when the mitral orifice is entirely free, the blood glides from the auricle into the ventricle without any impelling force from behind; so in disease, when the orifice is narrowed, the resistance does not produce any extraordinary effort on the part of the auricle to overcome it. And thus in disease as well as in health, through a narrow passage as well as a free one, the onward current of blood from auricle to ventricle is still without noise. That it is otherwise with the regurgitating current through the same passage, and that the murmur of the blood rushing backward from ventricle to auricle should be often signally loud, must be owing to the force of the ventricle, now engaged in impelling it."

The knowledge that the endocardial murmurs are

thus produced by valvular disease, the direct cause being either the passage of the blood onwards through the orifice, or its regurgitation, or both, impaired the previous apparent facility of diagnosis. It became thus impossible to tell, prior to death, whether the disease was seated in the aortic or mitral valve, but two general facts have since been obtained, which will materially aid the diagnosis. The first fact is, that endocardial murmurs are most plainly audible at that part of the præcordial region, which is nearest to the orifice from which they proceed. The second is, that endocardial murmurs are conveyed sometimes in one direction and sometimes in another, and that the orifice from which they proceed determines, in each particular case, what that direction shall be. Of these two facts, Dr. Latham inclines to lay greater stress upon the latter than upon the former, because the portion of the præcordial space, in which is contained the valves and their orifices, is so small that the mouth of an ordinarily-sized stethoscope would surely cover them all within the circle of an inch and a half or less, and thus the murmur of one orifice cannot be segregated from that of another.

"What then, if 'endocardial murmurs *are* most plainly audible in that part of the præcordial region which is nearest to the orifice from which they proceed!' This general fact, taken alone, cannot help us much in determining which of them is affected in a particular case, when they all lie clustered together at the same, or nearly at the same part of the præcordial region.

"But suppose we raise our ear, or the stethoscope, from this exact spot, and shift it an inch or two higher or an inch or two lower. Higher we may hear the endocardial murmur still, and lower we may lose it altogether. Or higher we may lose it altogether, and lower we may hear it still. Or both higher and lower we may still distinctly hear it. By this procedure we are following the endocardial murmur in the direction it takes after it leaves the orifice from which it is propagated, and we find how various the direction is, upwards in one case, downwards in another, and both upwards and downwards in a third. But still it is the orifice, from which it is propagated, that gives the murmur its particular direction; and this (it is said) may be taken for a general fact.

"Accordingly, when the endocardial murmur is conveyed in an upward direction, even above the basis of the heart, and still along the course of the aorta, and further still, as sometimes happens, along the subclavian and carotid arteries, the aortic orifice is its point of departure, and the valve, there situated, is the valve diseased. When it is conveyed in a downward direction, and to the apex of the heart, the auriculo-ventricular orifice is its point of departure, and the valve, there situated, is the valve diseased. And when it is conveyed both in an upward and downward direction, both in the course of the aorta, and to the apex of the heart, then it has two points of departure, and both the aortic and the mitral valves are diseased. Here the murmur, which is *one* to the ear, may be *two* in fact. The two are made one by being both synchronous with the systole of the ventricle. In this case the murmur from the aortic orifice is direct, and that from the mitral is regurgitating. Or the murmurs thus conveyed in different directions, as they are two in fact, may be two to the ear. But then one must be synchronous with the diastole, the other with the systole of the heart. In that case the diastolic murmur comes almost always from the aortic, and the systolic from the mitral orifice; and the diastolic and aortic murmur is not direct but regurgitating, and the systolic and mitral murmur is regurgitating still."

The passage of the endocardial murmur in certain directions, according to the seat of the valvular disease, will also aid us in forming a differential diagnosis of diseases of the same order of valves on the two sides of the heart, as regards the aortic and pulmonary valves. But Dr. Latham is doubtful whether the same rule would apply to the mitral and tricuspid:

"When the murmur, audible in the space between the two horizontal lines above described, is conveyed upwards and beyond the basis of the heart, the disease may be either of the aortic or of the pulmonic valves. The direction that it takes from this point must determine which of the two; for it may take more than one direction. When it is heard passing upwards for the space of two inches, and between the second and third ribs of the right side, then it is taking the course of the aorta, and the disease is of the aortic valve; and still more surely, if it be heard in the carotid arteries. But when it is heard passing upwards between the second and third ribs, not of the right but of the left side, then it is taking the course of the pulmonary artery, and the disease is of the pulmonic valve; and still more surely, if it be not at all heard at the same time in the carotids."

Valvular disease of the heart is generally confined to the left side, or, if both sides be affected, the left is by far more than the other; and the endocardial murmurs, generally, are produced on that side. Diseased valves of the right side alone are very rare, so much so as to prevent the medical practitioner being familiar with the peculiarities which belong to them.

The following are the conditions which tend to interfere with the course of the endocardial murmur, and perplex the diagnosis:—

"1st. The presence within the chest, and exterior to the heart, of substances having a more solid consistence than its natural contents, such as morbid growths of various kinds, or aneurismal tumours, or condensed portions of lung. These are able to conduct the abnormal murmurs, no less than the natural sounds, of the heart, to a greater distance, and in any direction, according to the place they occupy.

"2dly, The enlarged capacity of the heart itself, which is the most frequent consequence and concomitant of its diseased valves. The large dilated heart spreads its sounds abroad laterally. And thus, whether the murmur be traced in the course of the aorta, or not at all above the basis of the heart, it is often as loudly audible from mamma to mamma, and everywhere in front of the chest below the fourth ribs, as in the præcordial region itself; and often even far round towards the left axilla.

"3dly. The mere loudness of the endocardial murmur. The abnormal murmurs, as well as the natural sounds, of the heart, are heard to greater distance in proportion to their mere loudness, and that not only in the directions to which the current of the blood conducts them, but in all directions.

"Now, when these three conditions meet; the loud endocardial murmur, itself very widely audible, and the enlarged heart, ready to spread it still further abroad, and some solid substance within the chest ready, according to what its seat may be, to conduct it in any new direction, no wonder that the tendency of a diseased valve to convey and to restrict the same murmur within a particular channel should be sometimes counteracted and disturbed.

"To these several conditions I may add a fourth, viz. a peculiar quality of the endocardial murmur, giving it a high musical note. Such a murmur will sometimes refuse to suffer restriction to any certain space within the body. It will even carry itself outwards, and reach the ears of bystanders at a short distance."

Endocardial murmurs have been relied on, also, for estimating the magnitude and amount of impediment raised by the diseased valve to the passage of the blood, and for determining the kind of structural change which has been produced. The loudness of the murmur has been deemed to indicate the amount of disease, and of the consequent impediment; but this is true up to a certain point only, because, after the disease has proceeded to a certain extent, the murmur gradually lessens in intensity, and may ultimately cease altogether. This, Dr. Latham explains by observing, that the unusual sound is produced by unusual vibrations among the particles of the blood, the vibration being caused by the obstacle offered by the diseased valve:

"Now the sound must be in proportion to the vibration; and the vibration is in proportion to the amount of the obstacle and the quantity of blood and the rate at which it circulates taken together. Thus the endocardial murmur becomes louder and louder while the valvular disease is upon the increase, as long as the heart by its increasing thickness is still able to force a large current of blood through a moderately contracted orifice. But the endocardial murmur becomes fainter and fainter, and at length ceases altogether, as the valvular disease by its further increase, goes on still to narrow the orifice, and the ventricle with all its increasing thickness can only force the blood through it in a more and more slender stream."

With regard to the kind and quality of the endocardial murmur, indicated by the apparent resemblance to the sounds of the bellows, saw, rasp, or file, or to whistling or cooing, Dr. Latham is of opinion that these subdivisions, for such they are, only serve to confuse and perplex the student. The only practical point worth notice is, that the mere murmur can only tell whether it is produced from the inside or outside of the part; to form a more exact diagnosis as to its origin from valvular disease, and from which valves and at which orifice, then to the mere endocardial murmur must be added a reckoning of the time at which it occurs, and a reckoning, too, of the space within the præcordial region at which it is chiefly heard, and of the direction in which it is conveyed. The general history of the case, and of the sufferings of the constitution which preceded and attended the endocardial murmur, will serve to complete the diagnosis in respect to the essence and nature of the diseased condition of the heart.

In the third lecture, the subject of the endocardial murmur is pursued, and those cases in which its presence is not always indicative of valvular disease are examined:

"There are cases of endocardial murmur in which valvular disease is at least doubtful; and cases of endocardial murmur in which there is mechanical impediment, but no valvular disease; and cases in which there is neither mechanical impediment nor valvular disease; and there are cases, too, in which the ear itself is apt to be deceived into the belief of a murmur proceeding from the heart, when there is no such murmur in fact"

In some cases the murmur is not always present; it comes and goes, and the attendant circumstances must be examined, to ascertain its cause and nature. A person may complain of uneasiness and occasional palpitation about the heart, the impulse of which may be found to be slightly in excess, and the sounds louder and more diffused than natural. These are the common accompaniments of nervous disorder; but if the patient be made to walk briskly for a short time, the impulse of the heart will be considerably augmented, and there will be an unquestionable murmur. A few moments' rest will quiet this state, which may be again produced by exertion. In such a case it is reasonable to believe that there exists a slight mechanical impediment at the orifice of the heart to the circulation of the blood; and this view is supported by what obtains in some cases of rheumatic endocarditis, where, before the entire cessation of the murmur, it is for a time absent during repose, and present on exertion.

In some few cases, again, where the act of dying is slow and lingering, the endocardial murmur has been perceptible for a few days before death, but not until the dissolution may be said to have already commenced. This state Dr. Latham conjectures to be due to a commencing coagulation of blood in the ventricle, or even to inflammation of the endocardium, with the deposition of lymph, such as may take place at the very going out of life. The Doctor, unfortunately, had not had it in his power to verify this opinion by the results of an autopsy, but in a case, the details of which Dr. Maclachlan, of Chelsea Hospital, furnished him, in which the bruit de soufflet was very distinctly heard, no such cause was discovered. The pericardium was unusually thin and dry, and contained much less than the usual quantity of fluid. It was not rough, nor did it present any evidence of inflammation. The heart felt firm, was preternaturally small, and the left ventricle presented a beautiful specimen of concentric hypertrophy, the walls exceeding an

inch in thickness, and the cavity scarcely admitting an ordinarily-sized nutmeg. The right ventricle was healthy, and all the valves sound.

There are also other causes of the presence of the endocardial murmur. It may be produced by the force of the heart's contraction; this is a rare thing in adults, but common enough among children. Deformity of the chest may prove the mechanical impediment to the passage of the blood, and thus cause the murmur, in a manner similar to that in which valvular disease acts. Again, external pressure on the parietes of the chest may act as a mechanical cause of impediment to the circulation; Dr. Latham has known the murmur produced by the stethoscope being pressed too firmly on the parietes of the chest in a child, not nine years of age, so as to cause the ribs to sink a little below their natural level. Pressure thus exerted has often produced some unusual kind of endocardial murmur, but Dr. Latham has only known it once simulate the murmur of valvular disease, when the chest was free from deformity. In chicken-breast, again, the diagnosis is impeded by the change of relation of the heart to the walls of the chest:

"It often thrusts it forward, and brings its whole anterior surface in contact with the sternum and ribs. Hence in such cases the question, whether the heart be sound or unsound, becomes puzzling enough. Sound or unsound, its impulse is to be felt and seen in all the space at which it lies in contact with the chest, and the same space is dull to percussion. Extensive præcordial impulse and extensive præcordial dulness are the very signs of hypertrophy; and if to these be superadded the endocardial murmur, you have the complete signs denoting the commonest form of complex unsoundness which the heart is apt to undergo, viz. hypertrophy with valvular disease. But beware, now especially, beware, of creating the endocardial murmur by the application of the ear on the stethoscope to the præcordial region."

The murmur of respiration, which bears a degree of resemblance to the bellows' sound of a diseased heart, may in some cases be mistaken for it, and in some instances it has been carried into the ear with an impulse, as if it came from the heart. The method of clearing up the doubt is to auscult the heart, while the respiration is suspended for a quarter of a minute.

Dr. Latham has also noticed in persons who were undeniably consumptive, or were justly suspected to be so, a murmur which to the ear claims kindred with endocardial murmurs. But although the heart may be instrumental in producing it, it is not at all perceived within the præcordial region, but in a certain definite and circumscribed space beyond it. The following is Dr. Latham's description of the part in which it is audible:

"Fancy a line drawn from the left side of the sternum along the upper edge of the second costal cartilage, and continued an inch along the second rib; and another line drawn from the sternum along the lower edge of the third costal cartilage, and continued an inch along the third rib. Between these two lines a space is included, in the whole or in part of which a murmur is often audible coincident with the systole of the heart, when no such murmur can be perceived either in the præcordial region, or in the course of the aorta, or in the carotids, or in any part of the arterial system, but here and here only. It is a gentle bellows-murmur, quite obvious to the ear, and unmistakable in its character."

The pathological explanation of this fact Dr. Latham is unable to give; he has only a clinical experience of the matter, but he asks—supposing the pulmonary artery in its first division to be the seat of the murmur, does it become such in consequence of its own disease, or by reason of pressure or impediment reaching it from the diseased lung? Although the pathological cause of this phenomenon is as yet hid in obscurity, yet the fact of itself is one of great importance, as affording an additional sign in the diagnosis of suspected phthisis.

The endocardial murmurs, which remain to be noticed, are those "synchronous with the systole of the ventricles, audible in the præcordial region, and extensively diffused through the arteries, resembling the bellows-sound, and so having the commonest quality of endocardial murmurs, not distinguishable by the ear from those which proceed from mechanical impediment to the passage of blood, yet themselves springing from a different cause, which form a class by themselves, and a most important class it is."

These are dependent on a change in the relative proportions of the constituent elements of the blood —an impoverishment of the blood—or the state in which its red globules are deficient, and its serum in excess. That this is the real cause is shown both by its disappearance when the blood becomes richer, and is made to abound more in red globules, and by its presence in persons from whom blood has been freely abstracted in the treatment of disease, or who have suffered from excessive hemorrhage. The same state obtains in chlorotic anemia, in which there is a defect or failure of the assimilatory functions, whence the mass of blood is not replenished in due proportion to the expenditure upon the uses of the economy.

Accompanying this murmur in cases of anemia, or of exhaustion from great loss of blood, is a peculiar humming sound, which is not formed either in the heart or arteries, but was traced by Dr. Ogier Ward to the veins, and shown by him to proceed from the movement of blood within them:

"The vein, which offers itself most readily to the application of the stethoscope, and admits all the easy experiments which serve to certify the fact, is the internal jugular. Place the instrument upon the neck by the side of the trachea, and pretty close to it, and at the same time rest your finger upon the space between the angle of the jaw and the mastoid process; and when your ear has caught a continuous humming sound, and listened for a while and made sure of it, then press your finger firmly down upon the vein, and the sound, if it be the true venous murmur, will immediately cease; then raise your finger, and, if it be the true venous murmur, it will immediately return.

"A little management and address are needed to find this venous murmur, and then keep it within hearing when you have found it. I have seen it found by accident, heard for a minute, and then lost and never heard again. The instrument has been laid carelessly upon the neck, and the murmur has been audible immediately; and then, in expectation of making it heard to more advantage, the neck has been put upon the stretch, the chin raised and the head thrown back, or turned far round to the opposite side, whereupon the murmur has ceased. Then the neck has been relaxed, the head brought forward, and the chin inclined towards the sternum, but the murmur has not returned. The truth is, a very free current of blood is essential to the production of the venous murmur. A slight degree of pressure upon the vein will alter its character, and pressure very far short of that which would arrest the current of blood will abolish it altogether. And thus the neck being put upon the stretch, the muscles, which lie parallel with the vein and across it, are made to exercise pressure enough upon it to interfere with the free current of blood, and to stop the sound; or the neck being relaxed, the vein and the integuments get folded together, and so pressure is produced in another way, and this equally stops the sound. Try different degrees of pressure upon the internal jugular vein with the stethoscope when the venous murmur is distinctly audible, and you will find how lightly you must hold the instrument to keep it constantly within hearing, how inconsiderable an amount of pressure will obliterate it, and how each degree short of that which obliterates it will give it sundry varieties, and make it musical."

The occurrence of the endocardial murmur combined with the venous humming sound, is at once indicative of the impoverished state of the blood, and consequently at once points to the mode of cure. These murmurs are also accompanied by other symptoms significant of the condition of the circulating fluid.

The endocardial sounds which are produced by the pericardium in a state of disease are entirely new sounds, generated by the effect of the disease itself, and not exaggerated conditions of previously existing sounds, inasmuch as the pericardium in the healthy state is perfectly incapable of producing any sound or murmur. The cause, then, of the endocardial sound consists of strange substances separated from the blood and deposited on the pericardial surfaces, spoiling their natural smoothness and lubricity, interrupting their noiseless play upon each other, and causing them to grate together with a sound.

(To be continued.)

Travels in North America, with Geological Observations. By CHARLES LYELL, Esq., F.R.S. 2 vols. Murray.

Mr. Lyell is not the mere literary lion travelling for materials for gossiping pages, and vending his company for the privilege of more intimate access into those scenes which he is bent at the time, or afterwards determined to make scandal of. That is the misfortune of novelist-historians; their imaginations rule them more than their judgment, and truth, by habit, is strained or destroyed for the sake of effect. Men of science, on the other hand, if they are qualified by knowledge of the world and tolerably read in history, are perhaps the safest commentators on the characters and manners of a people to be met with. Their habitual searching after truth in matters scientific gives their minds a tendency to come at it in everything. And what are embellishments of style, happy turns of expression, smart sallies of wit, if this grand quality be wanting?

Mr. Lyell has not confined himself to the geology of America, he broaches opinions on the statistics and manners of the country, and it is not more than justice to say that they are reasonable, straightforward, and full of interest. The reflections of a sensible, honest-minded man, are peculiarly delightful by contrast with the ephemeral and conceited books hitherto written on America, in which the motive of criticism is palpably not truth, but, sometimes, wounded vanity, sometimes the bigotry which cannot see any good in what is *new*, and sometimes the vagrant humour of the literary coxcomb. We therefore invite all who value ingenuous and sound opinions to read these volumes.

The Diagnosis, Prevention, and Treatment of Diseases of the Heart and of Aneurism, with Observations on Rheumatism. By J. T. FURNIVAL, M.D., &c., late Physician to the General Infirmary, Hertford. London: 1845. 8vo., pp. 216.

Dr. Furnival's treatise contains some valuable observations on the more important affections of the heart, and shows that he has paid very considerable attention to the more frequent lesions of the central organ of the circulatory system; but we question the propriety of his having attempted to give a systematic bibliopole character to his limited remarks by the aid of extracts from Forget, Hope, Watson, and others. However valuable such foreign helps may have appeared to Dr. Furnival, they are misplaced in a page book of this kind; nor do they do our author himself justice, since the results of his experience in a rather obscure class of maladies would have told better had they been laid before the public in the form of a smaller volume, or, as we should have thought better, a series of *Clinical Observations* in one of our periodicals, in which all would have been the author's, and not half the property of somebody else. Dr. Furnival pays much attention to the *prognosis* of the various diseases treated of. For this we highly commend him, as too often it is a point which is lost sight of by authors attempting to improve our knowledge of a particular disease. Our author adopts the theory of Schönlein (see *Medical Times*, vol. x.), that in rheumatism there is lithic acid in the blood, which must be eliminated through the secretions, or obviated in treatment through the use of alkalies, in order that the disease be cured. By his assuming that this acid may exist in the form of *lithate of soda*, he obviates the difficulty that might be urged against the presence of any free acid, as the blood being an electro-negative body, will not allow of it. Our readers are well aware that Andral has shown that an excess of fibrine is present in the circulating fluid of acute and sub-acute rheumatism, but that it returns to its natural standard in the de-

cidedly chronic forms. This predominance of fibrine and acid are, according to Dr. Furnival, the cause of endocarditis and hypertrophy, as relations of the more acute forms of rheumatism, and to combat there the free use of alkalies is to be adopted; the liquor or bicarbonas potassæ being advised.

"This remedy may correct the two chief morbid states of the blood, and prevent irritation of the muscular ventricular fibres, and of the serous membrane as well. Such is my conviction of the value of alkalies in the diseases now under consideration, that I do not think either endocarditis or rheumatic hypertrophy of the left ventricle ought to be, or can be effectively treated without them."

Aconite is the great sedative of our author—the opiate of the heart—and which he strongly recommends in place of digitalis, &c. We fear, however, he sees something in monkshood that few find, when he asserts,—"I hope to see it take its place as an antiphlogistic, and also to see the lancet superseded by it in all cases of inflammatory excitement with want of vital power in the patient, when I am confident there will be fewer deaths from the nimia diligentia medici."

According to Bouillaud, endocarditis accompanies every case of rheumatic inflammation of the joints: Watson states one-third of rheumatic cases to be connected with some cardiac affection; M'Leod says more than one-fifth; Dr. Latham about two-thirds so suffer; but our author, who has prescribed alkalies for fourteen years, has met in no single instance with heart disease caused by rheumatism when his treatment has been fairly followed. We trust our readers may be as successful with this class of remedies as Dr. Furnival has been, if they think fit to try it.

As regards our own practical knowledge, we feel that it will not allow of our coinciding in *all* that our author says when speaking of the treatment of pericarditis: "bold venesections on the first day, then cupping and leeching as freely as possible—this is supposing there is no endocarditis;" let this *boldness* be somewhat softened down, and we agree in everything else.

Some useful remarks by Mr. Gibson, of the Nottingham Hospital, on the healthy and some morbid physiological relationships of the heart, &c., will be found added to the book, as also well selected illustrative cases of each form of cardiac malady treated by the author. In one point we differ materially from Dr. Furnival: his notion of his own characteristics. He fancies that he especially eschews theory, while we fancy that he is not only a theorist, but a very good one.

The History, Diagnosis, and Treatment of Typhoid and of Typhus Fever; with an Essay on the Diagnosis of Bilious, Remittent, and of Yellow Fever. By ELISHA BARTLETT, M.D., Professor of the Theory and Practice of Medicine in Transylvania University. Philadelphia: 1 vol. 8vo., pp. 393 1842.

Great admirers of our country, and of the many clever men it has produced, we do not shut our eyes to the talented productions of other nations. In chemistry, the continentals have, unquestionably, the advance of us, and it will require something more than a jog-trot pace on our part to keep up with them in other departments of scientific research. The work before us is "American born," but, if we may be allowed to prophesy, we should say it will soon gain its letters patent of naturalisation in the mother country. It is, without exception, one of the best books on the practice of medicine that we have seen for many years past; elegantly got up, beautifully written, displaying deep research and extensive reading, with a great amount of practical experience. The style reminds us strongly of some of our most esteemed ancient writers; and we could fancy Hippocrates (if now living) writing such a work—and really not so considerably its superior—with all the experience of the bygone centuries before him. The arrangement of the work is as follows:—Part I. Typhoid fever; II. Typhus; III. Bilious, remittent, and yellow fevers. If we give an outline of the author's plan in treating typhoid fever, it will serve as an example for the rest, which are arranged after the same manner. Chapter 1—Names and descriptions of the disease. 2. Symptoms: Mode of access, febrile symptoms, chills, heat, state of the skin, pulse. Thoracic symptoms: Respiration, cough, physical signs. Cerebro-spinal symptoms: Headache, pains in back and limbs: Mind, physiognomy, somnolence, vigilance, state of senses, state of muscles. Digestive and abdominal symptoms: Tongue and mouth, appetite and thirst, nausea and vomiting, state of bowels, abdominal pains, tympanitis. Miscellaneous symptoms: Emaciation, state of urine, epistaxis, eruptions, eschars, sequelæ. Chap. 3. Anatomical lesions: Of the circulatory apparatus, respiratory apparatus, brain and its membranes, digestive and abdominal organs. Chap. 4. Causes: Age, recency of residence, contagion, locality, season, sex, &c. Chap. 5. Varieties and forms. Chap. 6. Duration, march, and complications, peritonitis, relapses. Chap. 7. Diagnosis. Chap. 8. Mortality and prognosis. Chap. 9. Theory. Chap. 10. Treatment: Drs. Jackson, Nathan, Chomel, Louis, Bouillaud, De Larroque; miscellaneous. Chap. 11. Definition of typhoid fever.

It must strike every one acquainted with the subject, that this arrangement is masterly; and we can assure our readers that each department is treated with, at least, an equal excellence. Embarrassed, where so much is good, to select a specimen, perhaps the definition of typhoid fever may serve that end as well as any other:

"Typhoid fever is an acute affection; occurring, most frequently, between the ages of fifteen and thirty years, sufficiently often previous to the former period, and but very rarely after the fortieth year of life; attacking, at least in cities and amongst adults, in a majority of instances, persons who are recent residents; occasionally, and under certain conditions, the nature of which is unknown, capable of transmission from one individual to another; rarely occurring twice in the same person; more common in certain countries than in others, but not confined, so far as is known, to any geographical localities or regions; prevailing at all seasons of the year, and in all climates; sometimes sudden, sometimes gradual in its access; attended, at its commencement, with chills or rigors, not commonly very severe, and usually repeated, at uncertain intervals, for the first few days; then, with more or less feverish heat of the skin; generally, with increased quickness of the pulse; somewhat accelerated respiration; slight, dry cough; an extensive sonorous or sibilant ronchus; with pain in the head, back, and limbs; loss of the vigour, and, in grave cases, perversion of the faculties of the mind; dull expression of the countenance; more or less somnolence or watchfulness; giddiness or dizziness; ringing, roaring, or buzzing in the ears; occasional epistaxis; great loss of muscular strength; in grave cases, with spasmodic twitchings of the muscles,* especially those of the fore-arms and hands; with entire loss of appetite, and with thirst; sometimes with nearly a natural appearance of the tongue, and, at others, with a red, dark, dry, glutinous, cracked, trembling state of this organ; sordes upon the teeth and gums; occasional nausea and vomiting; frequent diarrhœa; abdominal pains and tenderness; these latter not unfrequently marked in the right iliac region; dulness on percussion over the spleen; meteoric distension or rigidity of the abdomen; the skin, particularly of the front part of the body, being usually the seat, in the course of the second and third weeks of the disease, of a peculiar eruption, not commonly abundant, consisting of small circular or oval spots, of a bright rose colour, slightly elevated above the surrounding surface, and readily disappearing under pressure; the blood, when drawn from the body, having its proportion of fibrine diminished in a degree closely corresponding to the gravity of the affection:—which symptoms differ, very widely, in their duration, in their march, in their severity, and in their combinations, in different cases; no one of which is invariably met with, and several of which are frequently wanting; but enough of which are almost always present to characterise the disease:—which symptoms, furthermore, may either gradually diminish in severity, and finally disappear between the twelfth and the thirtieth day of the disease; or may increase in severity, and terminate in death, between the seventh and the fortieth day from their access:—the bodies of patients exhibiting, on examination after death, in only a certain proportion of cases, enlargement, or softening, or both, of the spleen; and, in all cases, thickening, or redness, or a morbid transformation, or ulceration, or all these changes, of the elliptical plates of the ileum; with enlargement, redness, and softening of the mesenteric glands, corresponding, in their position, to the altered intestinal follicles:—which disease, thus characterised and defined, differs essentially from all others in its causes, in its symptoms, in its lesions; and is, in the present state of our knowledge, only to a limited extent under the influence or control of art."

We shall be excused for this long quotation by its excellence, which, after all, is not a partial, but pervading quality of the work. Dr. Bartlett is an admirer and follower of Louis, in his descriptive arguments; with the latter it would be well if the profession generally were better acquainted. On the access, symptoms, and morbid lesions, Dr. Bartlett displays an amount of practical experience seldom met with. The chapter on causes (including the important question of contagion) is a masterly piece of reasoning. The author, after examining a large amount of evidence from the highest sources, inclines to the opinion that it is contagious; not, however, very strongly contagious. At the conclusion of his remarks on contagion, the following observations, too good to be omitted, occur: "There is one other circumstance, bearing upon this question, which it is important to notice: I mean the immunity from a second attack, which seems to be conferred by the occurrence of the disease. M. Gendron gives a remarkable instance of this exemption. The village of Petit-Gênes, containing only fifteen persons, was visited by typhoid fever in 1826. Twelve of these persons suffered from the fever, and of the three who escaped, two had had it previously. In March, 1829, the disease reappeared in the village, apparently introduced by contagion, and was confined to a single family who had taken up their residence here subsequent to the year 1826. Five members of this family had the fever, and although they were constantly visited and nursed during the nights by their neighbours (the subjects of the disease in 1826), the fever did not extend beyond the family. Chomel says, that of 130 patients at the Hôtel Dieu, no one, so far as this point could be ascertained, had previously had the disease. Nathan Smith says, 'My own personal experience is strongly in favour of the opinion I have advanced of the non-liability of the same individual to a second attack of typhus; for, during the twenty-five years since I first attended patients in this disease, and in that time I have visited many hundreds, and have witnessed its prevalence several times in the same village, I have never known or heard of its recurrence in the same person. I once attended a numerous family, every member of which was sick of typhus except two, who escaped at that time; but, two years afterwards, when the disease again appeared in that neighbourhood, those two individuals of the family, and those alone, were attacked. In another family which I attended, consisting of eight persons, five of the eight had the disease during the autumn, and early part of the winter, and recovered. The next summer, the remaining three, and another person who had been added to the family after the former sickness, were attacked by it, while all those previously affected escaped.'"

It need hardly be said that this character of typhoid fever, if fully established, although not in itself positive evidence, does nevertheless constitute a strong ground of belief, resting on analogy, for the contagious nature of the disease. We have given this quotation simply because we believe, with a little ingenuity, it might be used as a ground of argument for either side of the question.

The chapter on the symptoms is elaborate, as is also that part of the work on the lesions connected with typhus. On the theory we will not dwell, yet in this part the author gives a very impartial view of all we know, or has been advanced on the subject.

Before concluding with our strong recommendation of this work, a few words on the treatment will not be deemed amiss. We are first given the plans

of Jackson, Nathan, Chomel, Louis, Bouillaud, De Larroque, Barthez, Fouquier, Dobler, Skoda, Gerhard, &c. With regard to alum, as proposed by some German writers, the author is of opinion there is yet no satisfactory proof of its success in arresting intestinal lesions. The author further states—

"I have already spoken of the unsettled and discordant state of the professional mind in regard to the therapeutics of typhoid fever. It would be no difficult matter to multiply and strengthen the proofs of this truth, already sufficiently shown by the foregoing details. This, however, would be but an unprofitable labour; in the present state of our knowledge, of no practical value. Under the circumstances in which we are placed, amidst the claims and pretensions of conflicting opinions, it seems to me that we are not now justified in the use of any ultra or exclusive system of treatment; like that, for instance, of Bouillaud or De Larroque. For the present, our management of the disease must be eclectic and rational, not exclusive and specific. In its early stages, unless in cases where there may be special contra-indications, it seems to be generally conceded, that a moderate antiphlogistic course is the best that can be adopted; and that active emetico-cathartics, if used at all, ought to be used at this same early period. In the subsequent progress of the disease, a mild, alterative and rational plan, keeping the bowels moderately loose by laxatives, when this is necessary, and meeting particular symptoms with such remedies as experience has shown to be most suitable, would appear to be most appropriate and most successful. After the first few days, in cases of moderate or average severity, with no special or urgent indication, it is quite clear, I think, that all treatment, in any way decidedly active, or perturbating, is to be avoided. The tendency of the disease, in all such cases, is towards a natural termination in health, and there is no evidence that the dangerous complications, which are liable to occur, can be prevented by any active interference. I may remark, in this connection, notwithstanding what has been said, that carelessness, or indifference, in the management of the disease, growing out of the unsettled state of opinion in relation to its treatment, and of the limited control which we possess over it, would be as criminal a dereliction of duty, as it would be unbecoming in a cultivator of a science, and a practitioner of the art of medicine.

"We may hope that our treatment of this disease will yet become more successful, and more uniform; more exact in its application, and more positive in its results. Many 'ministers and interpreters of nature,' faithful to their high vocation, and competent to its duties, are zealously and patiently occupied in endeavouring to accomplish this end. Guided by a sound philosophy; relying upon the one great means of ascertaining the properties and relations of all forms of matter, inorganic and organic, that of observation, they or their successors may yet find, by persevering experiment, or fortunate discovery, methods of modifying the living organization, and of correcting its disordered actions, which shall give us a much greater control over the disease than we are now able to exert."

We recommend Dr. Bartlett's book to our readers for general and careful perusal. We are certain that their time cannot be more profitably employed.

Rational Orthopedy; or, the Treatment and Cure of Spinal Curvatures and other Deviations. By A. M. Bureaud Riofrey, M.D. London. Hippolyte Bailliere. Paris: J. B. Bailliere. pp. 39.

This pamphlet contains nearly as much matter as one page of the *Medical Times*. In this small space the author has expressed his opinion in contradiction to that of all other orthopedists, though certainly in a sufficiently obscure manner. Two or three extracts from Dr. Arnott's "Elements of Physic," and Dr. Combe's "Physiology Applied to Health and Education;" a case with woodcuts, and a sweeping condemnation of every other practitioner's mode of treatment, *et voilà tout*. We must, however, do the doctor the justice to say, that his apparatus, as shown in his woodcuts, appears ingenious and we think applicable to many cases of spinal curvatures. We also agree with him in his remarks on the injurious influence of stays and pressure in the treatment of these diseases.

NOTICES TO CORRESPONDENTS.

Important.—*Several subscribers, in arrears, are requested to forward immediately the amount of their accounts, in order that their names may not be placed in our list of defaulters.*

A Reader.—*Mr. Kelly's Post Office Directory is got up immediately under the sanction and with the aid of the Post Office authorities; and on this ground, therefore, is more likely to be correct in its list of medical men than any other source. It was, indeed, this authenticity that induced one of the members for Finsbury (Mr. Duncombe) to attack Mr. Kelly's work in the House of Commons, hence his influence to preclude from it further Government assistance. Mr. Wakley did not join in the attempt.*

A Handsome Portfolio *for holding the* "Medical Times"—*very desirable to those who would keep the numbers clean for binding, and easy of reference—may be had, by order of any Bookseller, or at the Office, price 5s. An allowance is made to the trade.*

A Subscriber, Newcastle.—*The diploma of the University of St. Andrew's will certainly be recognised by the new Medical Bill, if it becomes the law of the land in its present form.*

A Student, *by referring to our advertising columns, will see a notice from the Society of Apothecaries to the effect that, in future, there will be no preliminary examinations. Hitherto the Pharmacopœia and Physicians' prescriptions have been reserved for the general examination, and the four first books of Celsus, and twenty-three chapters of Gregory have formed the preliminary, which might be passed at any period of the student's education.*

We regret to inform M. Tzerlecki *that we have not received any copies of the journal edited by him, in exchange for the regular weekly copy of the* Medical Times. *We therefore wish respectfully to decline, for the future, this one-sided mode of exchange.*

The conclusion of M. Parlset's éloge *on the life of the celebrated Philip Pinel, shall be given in our next number.*

Cautus *should have addressed his peculiar communication to Mr. Cooke, who has the sole management of the printing department.*

A Reformer.—*Two members of the Society of Apothecaries formed part of the deputation, consisting of five, acting for the body of general practitioners. They were present because they had the high and handsome duty to perform of abnegating the privileges of the society on the best possible terms for the general practitioners.*

A.—*We regret we cannot give our correspondent the medical opinions he solicits. The concession would be against our rule.*

M. N., *who asks us the meaning of paying "money into court," should consult an attorney on the subject. We may, however, give a definition by example. When the judge (Baron Platt) showed his opinion of the recent action against this journal, by saying that Mr. Wakley was "very thinskinned," and by ordering that the damages, and £30 costs, should not be paid to him, but to an officer of the Exchequer Court, he was ordering "money to be paid into court."*

Dr. Knox, of Belfast, thus writes to us:—

"In a notice of the 'Irish watering places,' inserted in the *Medical Times*, I believe of the 12th July, I find a statement to the effect, that one of the Irish mineral springs, most celebrated for the certainty and speed of their cures, 'derived its virtues *to* (from) the daily addition of a hundred weight of Glauber's salts.' May, I request therefore, that you will have the goodness to point out in what page of the volume it is stated that any of the Irish springs derive their efficacy from this source. The most cursory perusal of the work will show, on the contrary, that whilst Ireland can boast of great advantages in her watering places, and the variety and number of her mineral springs, it is candidly and directly stated that purgative waters are almost entirely wanting, and the few springs that possess an aperient quality derive it not from the presence of sulphate of soda, but the admixture of sea water. Whilst admitting to the fullest extent my liability to all fair criticism, whether favourable or unfavourable, I claim, as a simple act of justice, the insertion of this letter in the next number of the *Medical Times*, or, if that be inadmissible, the correction of a statement so injurious in any way that may seem most appropriate."

Dr. Knox seeks to correct a truth by two errors. Our passage is "derived from," not "derived to." The review does not say that his book mentions the two hypothetical spas, but that "it is reported *of two spas," &c. One of the spas was the Kilkenny College Spa, the other the Spa of Drumcondra.*

J. K., *who sends us the case of extreme coronatorial indelicacy and misconduct occurring near Limerick, has no remedy save a mandamus, which is out of the question.*

Mr. Kay *has our warm thanks.*

Senex, *if wise, will pay no attention to the Paul Pry notices and foolish fabrications of such a journal. They are below everything but contempt, and not worth much of that. The letter is left in the office.*

The communications on the Edinburgh University from Dr. Lewins and Philo-O. P. Q. will appear in our next. The other communications we have received on this subject shall have consideration.

We have received the report of the Association for promoting Cleanliness among the Poor. (Glasshouse-street, East Smithfield.) It appears to be doing much service to the poor of the vicinity, who aid it by a very welcome reception of its benefits.

J. Z.—*The conditions of the Medical Times prizes shall be reported shortly.*

The report in the Times was not *accurate.*

☞ Defaulters.—*We regret to announce that Dr. M. Manson, of Dunrossness, Shetland, and Dr. Harvey, of Edgar's-buildings, Bath, can receive from us no more of the Medical Times.* We cannot afford *to send journals on their system of non-payment.*

THE MEDICAL TIMES.

Saturday, August 30th, 1845.

His praise is lost who stays till all commend.—Pope.

Defeat, discomfiture, and disgrace, being great prompters to action, there can be no doubt that the present recess will be marked by renewed attempts to produce a factious division in the now united ranks of the Medical Profession. Ultimate failure is of course certain: it is but one link more in the chain of a very disastrous fatality; but to preclude that momentary appearance of even partial success, which falsehood and deception may create, let us exactly see in what position the cause of Medical Reform now stands.

The resistance of the College authorities, aided by the machinations, after dissension, of a few characterless and disappointed malcontents, having lost the Medical Profession a bill, by which old corporate interests were made largely to suffer for the good of the body of Medical Practitioners, we have now before us, in the Report of the Deputation of General Practitioners, the draft of a somewhat altered scheme, to which the National Association has assented, and which, after much difficulty, has secured the assent—though not the approval—of the two Colleges of Physicians and Pure Surgeons.

Now what is this scheme, considered solely in reference to the General Practitioners?

First. It annihilates the Apothecaries' Society at one blow. Thus the General Practitioner will no longer be badged before the public as "an apothecary," and no longer be *forced* to take his designation from the humblest, but from the highest, of his functions. The system of apprenticeship which identified a profession with a trade, will thus also disappear; and we shall be delivered from an evil always objected to—a powerful medical government with no responsibility, and a national institution of medical science without any encouragements to cientific enterprise

Secondly. The General Practitioner has a Royal College of Surgery and Medicine created for him, and placed under his own guidance. He commands his own funds, appoints his own officers, does exactly what he conceives to be useful to his own order, and its domain of Medical Science; fixes his own curricula of studies and *modes* of examination to his own candidates (five years' professional preparation being the minimum); and, finally, has the free power of extending to the distinguished members of his own body all the emoluments and honours which belong to a Royal College having from 12,000 to 20,000 members!

Thirdly. No man, for the future, will be received into his body who is not at least a member of the College of Surgeons, and has not undergone a second examination, testing alike his competency and respectability, by the Colleges of Physicians and Surgeons. For the future no man will thus be a General Practitioner who, in addition to a medical education, has not attested twice a thorough surgical competency.

Fourthly. The body of General Practitioners will be a united whole—comprising in one College all legitimate Practitioners—from all of whom a complete and uniform education will be insisted on.

Fifthly. The present privilege of repressing quackery will be transferred from an irresponsible corporation to the Profession itself. The members of the New College will decide for themselves with what vigour they will punish illicit practice.

Sixthly. Those portions of the former schemes, by which General Practitioners had education deteriorated for their class—their members placed on an equality with two years' students (inceptors of medicine)—their appointments to public institutions limited according to the will and pleasure of the Council of Health—these, and enactments in a similar spirit, are wholly abrogated.

Such are the changes generally which have at length been negotiated for the General Practitioner by the Deputation of the National Association. What have they given for them? One concession. The College of Surgeons, instead of getting from us twenty pounds for its customary examination and diploma, will get fifteen pounds for joining with the physicians in accrediting us with an extra diploma. To us the arrangement is not pleasant, but in what particular is it worse than that which now exists? Besides, it is obvious the arrangement cannot last longer than will be convenient to the New College, which, by the time it can spare the *éclat* of the second diploma, will have the power of dispensing with it.

Now this is the COMPACT OF GOVERNMENT with the representatives of the National Association; and it is by this *compact*, and nothing else, the National Association and the Profession will stand or fall. It required from us a compromise, as it did from the two other parties concerned; but, being agreed on, we stand to it ourselves, and insist that it shall be adhered to by others.

In what way, then, do we regard the discrepancies between this compact and the newly reported bill? We regard them as the result of an official oversight. We have the best authority for saying that they are so regarded in the quarter where the oversights can be immediately altered, and that an understanding already exists that they will be altered.

But suppose they are not altered? We have but one course to pursue:—to give the Bill our most determined opposition. That is our advice—and that we have no doubt will be the policy sustained by the National Association. They have proclaimed already that they have gone to the utmost verge in their career of concession, and we have no doubt that if the final compact be broken, they will, in the words of their own address, assume that position of determined hostility to the opposing corporations that has been so madly forced on them—and accomplish our project of a voluntary Faculty of Medicine, including ultimately within its folds nineteen-twentieths of the Medical Profession of this country.

Taking this view of the National Association's conduct in reference to the Bill, it was not without pain that we noticed an article in the *Times*—from certainly a very clever pen—insinuating, from a comparison of dates, that the Report of the Deputation was published with some collusive project of favouring or helping the faulty scheme of the Minister.

There could be no greater mistake, either as regards facts or interests. The report was published several days before the Bill *was* printed, though not several days before it was ordered to be printed; and the Committee of the National Association, so far from supporting the Bill with its present omissions, will, we have every reason to be sure of, give it a very sturdy resistance. The *Times* has really done great services to the cause of Medical Reform: let us trust that it is not going now to undo them. It would ill become the *Times* to play the *rôle* of the large animal, giving much milk and then upsetting the pail.

THE MEDICAL TIMES AND MEDICAL PROFESSION.

The Medical Times can indulge no "whinings" about professional ingratitude; no complaints about its being unappreciated. We have no very defined idea of how much we are entitled to from the Profession, though, with a common vanity, we conjecture it to be no trifle; but, whatever it be, we are sure of this, we receive our deserts and more. Medical men are not the begrudging paymasters, the lukewarm supporters of an *honest* advocate, it suits the adverse fortunes of some of our contemporaries to represent them. Testimonials, spontaneous and hearty, are reaching us every day, of esteem and kindness from some professional brother or literary contemporary; and, to escape that appearance of neglect or ingratitude which the impossibility of private replies might cause, we take the present public occasion to offer to each and all of our panegyrists our warmest and most grateful acknowledgment.

Unquestionably, the most important of these manifestations of regard and support is that for which we are indebted to the National Association of General Practitioners. Numbering more members than any half-dozen medical associations this country has yet seen; having a committee of more than a hundred gentlemen of the largest practice and standing in the Profession, and exercising an influence on legislation which has saved the whole medical body of Great Britain from being reconstructed on the crude notions of a few College functionaries—from such a body—so prudent, so potent, so wholesomely influential—it was, indeed, a high gratification and rich reward to receive an assurance like that contained in the following resolution:

"Moved by J. BIRD, Esq., Hon. Sec., and seconded by H. ANCELL, Esq., Hon. Sec.

"That the Committee desire, at the close of the present Session of Parliament, and previous to adjourning their own sittings for the recess, to express the obligation under which they feel to certain portions of the Daily and Medical Press for their most efficient advocacy of the cause of Medical Reform, and particularly their sense of the talent and zeal with which the interests of the General Practitioners have been advocated in the pages of the *Medical Times*."

If anything can add to the pleasure of such a resolution, passed by such a body unanimously, it is the significant fact that it was proposed by the two gentlemen who—where immense self-devotion was an attribute common to all—*pre-eminently* distinguished themselves in accomplishing their mighty organisation;—we mean the two Honorary Secretaries of the Association. Acquainted, as they are, with the whole question of Medical Reform, and the effect of the different agencies that have been brought to bear on it, the handsome way in which, backed by the responsibility of their official position, they have volunteered to testify to the utility of our humble and independent labours, is indeed gratifying. We do not vex language in the attempt to express our acknowledgments to them, to the Committee, and to the Association, simply because they will accept with more pleasure the practical gratitude contained in a still more earnest attention to those professional interests of which they have shown themselves such efficient guardians.

Passing from this index of the *Profession's* opinions, we will give *one* specimen of the unsolicited suffrages which are every day reaching us from one or other of our respected literary contemporaries. The following is from the *Devonport and Plymouth Journal*—a journal of whose respectability and large circulation we have frequently heard, but with whose management we are entirely unacquainted:—

"Little as we profess to be versed in the healing art, we open the pages of the *Medical Times* with an interest that, to ourselves at least, scarcely attaches to any other professional publication. There is in the articles generally a spirit—a rich 'sauciness,' which, in many cases, serves to disguise or conceal the too often nauseous, though essential truths, which such publications are intended to convey; and even the general reader cannot fail to be struck at the rare, though agreeable, combination of first-rate literary talent with profound scientific and professional research, which this work displays.

"*We conceive that the medical world must be much indebted to its projectors. At a price below that of most weekly newspapers, they are supplied, not only with the current intelligence of 'the Profession,' but with first-rate original matter, in the form of Hospital Reports, Lectures, &c.*, while copious gleanings from the British and Foreign Medical Press afford all that is essential in order to keep pace with the many improvements of the day; in fact, in periodical literature, of medicine and surgery, no other work can be needed.

"We have besides the testimony of professional friends, on whose judgment we rely, supporting our own previously formed convictions, that the merit of this work is not confined to its spirited style and general good management; it is in every sense a most valuable *professional* work, and as such we cordially recommend it."

A fact or two are touched on here that are well worth consideration. Till the *Medical Times* assumed its full development, under the present management, medical men were compelled either to abstain from reading medical journals altogether, or to pay one shilling for *less* information (and far worse digested) than is contained in little more than the half of the twenty-four pages of a single number of the *Medical Times;* in other words, they had to pay a shilling for what now they procure for about one-fourth of that sum. As our contemporary hints, we give weekly a volume of original scientific matter from superior pens, for less than the price of a common weekly newspaper, *i. e.*, do more, and in a difficult path of literature, for less money than any journal, probably, in Europe. We have thus completely broken up the old forms of medical journalism; we have *enforced*, in the

region, a practical revolution, which must be of immense convenience to Practitioners, and of the utmost service to the progress of our science. The fate of those who usually make themselves the benefactors of a class, is to be praised and neglected. "Laudatur et alget." Their improvements are accepted, and themselves left unsupported. It is our happy experience to find another result. The whole Profession has rallied round us with gratifying unity. Wherever there is a medical man, there—save in some ungainly exception—is a reader of The Medical Times. Some, indeed, of our countless friends carry their support of us so far as to discountenance every journal that expresses against us the hostility of its wounded jealousy or vanity; and rivals that might have flourished aiding us, are perishing opposing us.

REGISTRATION OF DEATHS.

We have received several letters in reference to the plan adopted by the Registrar-General, of securing a registration of all deaths, with their causes, occurring in the United Kingdom. Our correspondents in general, we regret to perceive, look on the innovation with very unfavourable eyes. Let us, therefore, say one word on the subject.

The statistics of death of a nation is one of the most valuable contributions that can be made to medicine. It will throw light on a thousand points, obscure and dark without it; and lead to inductions, both in the prevention and treatment of disease, which may make our art doubly and trebly a boon to society. Till the statistics of deaths are better unfolded, there can be no faultless legislation on the sanatory condition of the people.

There can be no stronger appeal *to us* in favour of this admirable scheme of registration; it recommends itself to us on the grounds of a very enlarged philanthropy and high professional standing. But there is another.

The Registrar-General has made this innovation a salutary and not ineffectual check of quackery. The blank forms of certificates are sent only to qualified practitioners. The district Registrars will receive no certificates from any person (quack, chemist, druggist, student, or what not), without a diploma. In this way the irregular practitioner is exposed and denounced to his district, while the educated doctor is pointed out as the only person enjoying the confidence of the Government.

We are glad to see the Government thus honourably, and for a useful public purpose, asking the services of members of our Profession, and we cannot in this case join in the complaint that the Registrar-General (Mr. Graham) has not made the services he asks matter of remuneration. A blank form may be filled up in a second, and few qualified Practitioners have a dozen deaths per annum, we can hope, to register. What payment would meet such a service? The plan of payment would indeed offer such an impossibility, that, if necessary, the idea of registration *must* be abandoned.

Let us trust, therefore, that our readers, including our malcontent correspondents, will look at this improvement, with its small trouble, as a boon both to society and to science, and that they will gladly lend themselves to carry out the aim so worthily sought by the Registrar-General.

The council of the Sydenham Society have determined on reprinting the three volumes issued during the first year, namely, "Hecher's Epidemics," "Louis on Phthisis," and Sydenham's works in Latin.

SUPPOSED CASE OF POISONING.

A coroner's inquest was held at Bath on Friday, August 15th, and adjourned to Saturday, 23rd August, on the body of Lieut.-General George Dick, which was exhumed for the purpose, after having been buried nearly eighteen months. It appears that the general died suddenly on the 13th March, 1844, and that his death was attributed to apoplexy, and certificates to that effect were given by two medical men, neither of whom had seen the patient during life. We extract from the *Times* the principal evidence which is of any interest to our readers.

Joseph Cuff stated that he was butler to the deceased; the general died on the 13th of March, 1844; at the time of his death he was living at 4, Catherine-place, Bath. The general died at a quarter-past 12 o'clock; he had appeared to be in his usual health till half-past 11 or 12 o'clock. Witness took him his breakfast at half-past 8 o'clock, of which he partook, and the general at half-past 10 o'clock read prayers as usual; he had no difficulty in reading. Witness took him a cup of chocolate at a quarter-past 11; he usually took chocolate at that time. Witness did not prepare the chocolate, but merely put the sugar in it; the general did not take milk The cook gave him the chocolate. He left the chocolate with the general; he was then in the bedroom of Mr. Thomas, his grandson, usually called the back parlour, and adjoining the dining-room. At half-past 12 o'clock Captain Henderson called, and Mrs. Brickdale, the general's daughter, requested him to inform the general of the fact. He accordingly went to the general, and found that he had altered in appearance. He was paler than usual, and appeared to be inclined for sleep, with his mouth a little open, and his eyes a little dim. He was not accustomed to sleep at that hour of the day. He told the general of the captain's arrival, and he replied, "Very well, Cuff, I will go and see him." He did not then stir. Miss Dick, his daughter, was then in the room lying upon the bed; she was generally in attendance on her father. The general smoked a cigar that morning; he very frequently smoked; he had part of the cigar in his hand at the time the visit of Captain Henderson was announced. He left the general and went down stairs. Mrs. Brickdale and Mr. Thomas, her son, were then in the dining-room. He almost directly went up stairs again, with the tray to lay out the luncheon. There was no one in the dining-room then, but Mr. Thomas was with the general, and called witness to assist him. He went to Mr. Thomas, and found the general at the bedside, on his hands and knees, and Mr. Thomas trying to lift him up. Mr. Thomas said, "The general has had a fit." He assisted in lifting the general up, and laid him on his knees, he sitting in the chair. The general gave one long sigh, his head fell back over witness's shoulder, and he died. The general was not accustomed to fits during the time he was in his service. There was no one in the room then besides Mr. Thomas, the general, and witness. He supposed Miss Dick left on the captain being announced. Mr. Thomas ran for a doctor, and the first person who entered the room was Dr. Spry, who said that the general was a dead man. Mr. Thomas and Dr. Daniell immediately followed. [Here a slight interruption took place, in consequence of the witness fainting, induced, probably, by the heat of the room, and fatigue in walking very quickly into Bath. Having revived, he thus continued.] None of the servants knew of the death of the general until half an hour after it occurred. Dr. Spry bled the deceased in the temples and in the arm, but no blood flowed; he did not think a drop came from either part. Shortly after Dr. Daniell, Captain Henderson came into the room. No one else entered the room for two hours afterwards; the family were only told that the general was ill; the death of the general was kept from the servants, because it was thought they would tell the ladies, and it was agreed that they should not be told suddenly of his decease. Mr. Thomas proposed that the general should be buried without an inquest being held, as he did not wish to disturb the house. Witness did not know the occasion of Mr. Thomas's remark. He saw no bottle in the general's room. [By a Juror: He had no notice to leave the family till after the general's death.] He did not think the deceased had been sick that morning. The general did not drink the chocolate in his presence; he afterwards washed the empty cup. The general was not in the habit of taking medicine.

Mr. Thomas Barrett, surgeon, of Bath, deposed that on Friday, the 15th day of August, he attended at the Abbey Cemetery and saw a body exhumed, which was pointed out to him as that of General Dick. The coffin was opened, and then taken into the crypt, where the examination commenced. The face evinced a little sign of decomposition, but was instantly recognised by the parties present. Decomposition had made but little progress in the body. Witness opened the chest and found the viscera in the condition to admit of an anatomical examination. The lungs were very much shrunk, but still crepitant or containing air, and exhibiting to a certain extent their structure. There had been a slight old adhesion of the pleura, and the right side of the chest contained about half an ounce of bloody serum. The heart was shrunk; it was examined with very great care, but exhibited no disease. It was perfectly healthy throughout its structure, as also was the aorta, the principal artery of the body, which he traced for several inches and found quite free from disease. The abdominal viscera were removed with great care and delivered to Mr. Herapath, having been properly sealed, &c. The brain was lessened in size, and from the position of the body was found more particularly in the posterior part of the skull. The dura mater, or membrane covering the brain, presented its usual firm character; the brain itself was reduced to a soft pulpy mass; still, however, its anatomical parts admitted of demonstration. The bloodvessels carrying red blood were still visible in the membranes and in the brain itself; no disease could be detected in the brain. There was no bloody effusion; there was serum found in the ventricles, but not more than would be found in a healthy brain; indeed, he should say rather less. He was prepared to say that death was not caused by sanguineous apoplexy; whether it was caused by serous apoplexy might be matter of opinion. All he could say was, there was no serous effusion.

The coroner said, it would be very satisfactory if the witness could give an opinion on this point, as the certificate sent to him at the time stated the death to have resulted from serous apoplexy.

Witness said the case was a very unusual one, from the length of time which had expired since the death and interment of the deceased; he did not feel himself in a position to say whether the death might have resulted from serous apoplexy; all that he could say was, that he found no serum in the brain to favour the suspicion that such had been the case.

Examination resumed.—On Saturday last, in the presence of Dr. Daniell, Dr. Paris Dick, Mr. Coucher, surgeon, Mr. Maule, and Mr. Herapath, he examined the stomach and intestines, and the abdominal viscera generally. The stomach externally presented a purplish-red appearance, the vessels being considerably congested; the intestines externally, with the exception of a point, to which he would refer presently, exhibited no unusual appearance; they were loaded with fat, as were the viscera generally. The liver was shrunk, but firm. The intestines were so free from decomposition, that they admitted of perfect investigation. The gall-bladder was empty, but quite sound. The spleen had degenerated into a cheesy, fatty mass. The pancreas was little altered. Internally the stomach presented great vascularity at its larger end, extending up to the œsophagus, or gullet. The inner membrane of the stomach was entire, but rather soft, and the other portion of the stomach was soft and pale throughout. On the first part of the duodenum, the first of the small intestines, he found a patch (nearly two inches by about an inch and a half) of inflamed intestine, having the appearance of extravasation, of irregular shape, and deeply tinged with a bright yellow; striæ, or little rays of a dark colour, were seen running from this bright-coloured patch to its circumference. The yellow colour had infiltrated through the membranes, and presented externally the same appearances. On the internal surface this patch was circumscribed by inflamed intestine; the same appearances presented themselves lower down in the intestines at the junction of the

duodenum with the jejunum, only wanting the yellow tinge; still lower down in the intestines, where the jejunum passes into the ilium, the intestines exhibited for several inches great inflammatory action; the large intestines showed no morbid appearances.

Mr. W. Herapath, of Bristol, philosophical chemist and lecturer on toxicology, was next sworn, and deposed as follows:—He made an examination of the stomach, intestinal canal, and liver of the deceased. He commenced the chemical examination with the contents of the stomach, and then proceeded with the contents of the intestines. He then examined the texture of the stomach itself; then the substance of the intestines, and lastly, he examined the liver. The result was, that no metallic or mineral poison could be found. He particularly examined the yellow spots which had been so accurately described by Mr. Barrett. He dissected them out, and, after a most rigid analysis by three or four different processes, he succeeded in finding that the yellow stain was entirely occasioned by the colouring matter of the bile; the appearances of those spots were so very suspicious that of course he devoted considerable time and trouble to ascertain, not only that they were not caused by poison, but what they were caused by. There were some poisons which he could not have found: prussic acid nor morphine, if it had been absorbed. It might have been absorbed in less than twenty-four hours, from the circumstances of opium being very rapidly absorbed into the system. Any organic poison soluble in water he should not have expected to find, because the fluids of the stomach and intestines had passed away.

The coroner feared there would be considerable difficulty in arriving at the symptoms which immediately preceded death, as the only members of the family who were with the deceased at the time were Mr. Thomas, Mrs. Brickdale, and Miss Dick, who were not in Bath.

Mr. Barrett was again questioned as to the cause of death. He said that he found sufficient morbid appearances in the stomach and bowels to cause death, but not as suddenly as had been described, unless accompanied by a shock to the nervous system. There were many causes which might have led to the appearances of the stomach and bowels. They might have arisen idiopathically or symptomatically; they might have arisen from some diseased state of the system, or from the effect of some irritant applied to them. No medical man would be in a condition to say positively that they were caused by an irritant unless he knew that an irritant had been applied. If it had arisen from an irritant the time it would have required to cause death would depend on the character of the irritant, and the quantity applied.

The witness was further examined at great length by Mr. Greaves and the jury.

The Coroner inquired whether the approach of death must not have been felt some time before?

The witness said, it would be very difficult for him or for any other medical man to say that such inflammation could exist for a long time without pain, unless that pain was masked by the influence of very powerful narcotics, or by greater pain existing in another part of the body. A great amount of inflammation might exist in some surfaces, such as the mucous lining of the stomach and the intestines, and not produce such an amount of pain as the same degree of inflammation would cause if it existed in a serous membrane.

The coroner.—Was there sufficient inflammation to cause death in the absence of any nervous shock?

Mr. Barrett certainly thought that there was sufficient to cause death, and that a nervous shock would only accelerate it.

The witness was again pressed to state what, in his opinion, was the cause of death. After explaining the difficulty of giving any more than a general opinion, he said he found no disease of any note, but the inflammation of the mucous membrane of the stomach and bowels.

Dr. Daniell was next sworn, and stated that he was called in to see the deceased on the morning of his death, at about 11 o'clock, by Miss Thomas, the deceased's grand-daughter, who informed him that her grandfather had been taken dangerously ill. Upon arriving in the room he found the general raised in an arm chair; he was dead. From what he could ascertain, after a lengthened inquiry, he came to the opinion, that his death had been caused by serous apoplexy, and wrote a certificate with Dr. Spry to that effect. Mrs. Brickdale, Miss Dick, and Mr. Thomas informed him what the symptoms had been,—that he had giddiness and nausea, and complained that when he tried to read the letters went round and round. They said they had given him some peppermint-water, but he did not swallow it. Witness almost entirely coincided with what Mr. Barrett had said, except that he had seen cases of spontaneous inflammation where there had been no previous disease, which had caused so great a shock to the nervous system as to produce syncope and death—death quite as sudden as that of general Dick. He had seen cases of that kind in his own practice; at the same time, he should say that serous apoplexy might also have produced death in the same sudden manner. The persons in whom he had seen inflammation giving a shock to the nervous system produce death, were aged persons and in quite as good health as General Dick; many cases of the kind were recorded by Dr. Abercrombie.

A juror.—Did you in your examination of the body see any thing to induce you to change your former opinion?

Witness.—Nothing. I was not present when the brain was examined, and had only taken that from Mr. Barrett's very accurate description. Had no doubt whatever in my own mind that, to the best of my belief, he died a natural death.

The coroner summed up at great length, observing, that if they were of opinion that the death was natural from serous apoplexy, they would return a verdict of died by the visitation of God, but if they were not satisfied, they could find that he died suddenly from some cause unknown.

The jury having consulted for a few minutes, came into court and returned the following verdict:—"Died from inflammation of the stomach and bowels, but how produced there is no evidence to show."

THE LATE MIDWIFERY CASE.

In answer to our numerous correspondents on the subject of the late unfortunate midwifery case, we give below particulars which transpired at the inquest. Any remarks on the matter would be ill-timed until Mr. Hawkins has taken his trial; should we find it necessary at a future period, however, we shall offer our readers a few strictures on these cases, which, unfortunately, seem neither few nor far between. The following are the facts as they appeared in evidence:—Mr. Hawkins, surgeon, of 54, Hatton-garden, was called to attend Elisabeth Anne Crowder* on the morning of Wednesday, 6th August, during her confinement. About eleven o'clock the deceased was delivered of a male child, and shortly after she was seized with violent pain, and expressed an opinion that she was about to give birth to another child, at the same time asking Mr. Hawkins if he did not require further assistance. Mr. H. replied, that if twenty medical men were present they could do no more than he, that there was not another child, and that there merely remained a portion of the placenta to come away. Mr. Hawkins remained with deceased up to five o'clock on the following morning, when he left to procure some medicine for her. During this period much violence was used, and the deceased complained much of the excruciating agony she suffered. Ultimately the intestines protruded through the vagina.

This we gain from the witness Sarah Thornton.

Mrs. Elisabeth Smith proved, that she was called up at half-past five o'clock on Thursday morning to attend the deceased, and that she remained with her until her death, which took place the same evening at half-past six. Shortly before her death she stated to witness, as well as to the clergyman who attended her, her conviction that Mr. Hawkins "had murdered her."

Mr. John Thorn, of No. 4, Mylne-street, Pentonville, stated that he saw the deceased on the morning of the Thursday, about nine o'clock. He found large portions of the intestines protruding, and the head of a child presenting; the deceased's face was pallid, and the pulse feeble. Witness lost no time in delivering the deceased of the second child, which he effected with the whalebone fillet.

Mr. Gibson, another surgeon, also arrived, removed the second placenta, and returned the protruding intestines. A large laceration was formed in the posterior wall of the vagina.

Mr. Gibson and Mr. Bartlett also corroborated the material points of the evidence.

Dr. J. Hall Davis, of Russell-street, Fitzroy-square, lecturer on midwifery, made a post-mortem examination of the body in the presence of Dr. Forbes, Mr. Thorn, and Mr. Gibson. Mr. Hawkins did not attend, although he had a written notice sent him of the time it was to take place. The witness described the lacerations before alluded to, more particularly the rent in the posterior portion of the vagina. Witness had no doubt that the latter injury was done with the hands in endeavouring to separate what was considered by the medical man to be the placenta. The injuries received were the cause of death.

The evidence having been summed up, the jury found, "that the death of Elisabeth Ann Crowder was produced by the ignorance and unskilful conduct of James Hawkins." This being in fact a verdict of manslaughter, Mr. Hawkins was committed to Newgate to take his trial on the coroner's warrant.

THE FAKEERS OF INDIA.

(To the Editor of the Medical Times.)

Sir,—In the course of last winter I gave some attention to the inquiry regarding the jogi or fakeers of India, who have been represented as capable of reducing themselves to a state of apparently suspended animation or trance, (which I conceive may be most aptly likened to the state of hybernation of some of the lower animals,) during which they have suffered themselves to be buried for considerable periods of time, and come to life again, after exhumation. I was aware that much scepticism had existed on the subject, most parties having alleged the existence of collusion, whereby they had been enabled to perform these apparently extraordinary feats.

On a careful investigation, however, of all the particulars which I could meet with regarding these cases, compared with my personal experience of self-induced hypnotism, and the well-attested case of the late Col. Townsend, I came to the conclusion that there was far more reason to infer that the said feats were real, than that they had been accomplished by collusion, as alleged. With the view of arriving at the truth with the greater certainty, through the kindness of friends to the inquiry, I had the subjoined queries printed and circulated throughout India; and I have already had some most important and direct information, which leaves no doubt of the fact that such feat *has been done with success, under circumstances which rendered collusion impossible.*

Before publishing a detailed report of the facts to which I refer, I am desirous of obtaining all the additional information I can bearing on this curious physiological question, as to the possibility of man acquiring by art the power of throwing himself into a state of apparently suspended animation or trance, similar to the hybernation, or winter sleep of animals. Will you therefore have the kindness to publish the subjoined queries in your Journal, and permit me respectfully to solicit from your intelligent readers the favour of any information they can communicate relative to the feats of these *eastern devotees*; and also in regard to well-attested cases of *trance and catalepsy* which have occurred in Europe, or elsewhere? The favour of being allowed to authenticate any information, by publishing the names of parties communicating it, would be most desirable; but where parties, from particular circumstances, have any delicacy on this point, I shall be glad to receive information and observations *privately authenticated*, and with the express understanding that their names shall *not be made public*. I hope the general interest and importance of the inquiry, in a scientific point

of view, will be deemed a sufficient apology for me, in making this appeal.

I remain, Sir,
Your most obedient servant,
JAMES BRAID.

3, St. Peter's square, Manchester,
August 22, 1845.

Queries.—1st. In reference to the fakeers who have submitted to be buried alive for various periods of time, and have survived on being dug out of their graves or places of confinement—reports of which have been published by the Hon. Capt. Osborne, Lieut. Boileau, and others,—be pleased to state whether, consistently with your knowledge, there has been any positive proof adduced to warrant a belief that these feats were accomplished by collusion.

2nd. If you know of any positive proofs of this nature, will you be good enough to state them, and to indicate where they may have been recorded, and to what particular fakeer the impeachment refers?

3rd. What are the grounds on which, from personal evidence, or from the testimony of trustworthy individuals, eye-witnesses of the fact, you are satisfied there was no imposture or collusion, but that the fakeer really possessed the power of suspending his respiration, and remaining for any given length of time without food or air, under ground, in the manner described by Capt. Osborne and others?

4th. If you are satisfied that the fakeer was actually buried in the way described, do you believe that he remained under ground all the time till he was disinterred, or that (as alleged in query 1,) there was collusion with other parties, by whose means he was intermediately relieved from his confinement, or supplied with food, and replaced shortly before the time fixed on for his disinterment? State also whether, from the precautions taken, it was practicable for any confederate to disinter the fakeer, or supply him with food, without being discovered. Be pleased to state the grounds of your belief, that such acts of collusion were not practised.

5th. In conclusion, be pleased to state, with reference to the details already published, any further particulars with which you may be acquainted of the burial and disinterment of the fakeer at Lahore; and of his personal appearance before and after; as also any other circumstances which to you appeared conclusive in favour of the reality of the fact, or otherwise. State also any and what grounds of suspicion in regard to the fact might exist, from any thing observed at the time of interment and disinterment—such, for example, as his breathing, pulse, heat of his body, his manner and looks, and mode of recovering, &c. &c.

JAMES BRAID.

MISCELLANEOUS CORRESPONDENCE.

BELLADONNA.—In Dr. Williams' lecture, reported in the *Medical Times* of the 9th August, I observed a very serious mistake regarding the exhibition of belladonna, which I supposed would have been corrected in the last number; this not having been done, permit me to direct attention to it. Dr. Williams' words are, "some persons think that scarlatina may be prevented by small doses of belladonna. This notion originated among homœopathists, but it may be useful, independently of that doctrine, *in doses of from three to four grains, twice or three times a-day.*" I have prescribed the extract of belladonna for a great many persons, and often as a prophylactic against scarlet fever, with, in my belief, signal success, but I never exceeded the dose of one grain for an adult; and I am of opinion that the consequences of a dose of "*three or four grains*" would be, if not fatal, extremely perilous. The symptoms produced by its administration to healthy individuals are very various. A young lady was seized with a bad form of scarlet fever; and, in order to prevent its extension in the family, consisting of five servants, ten children, and the parents, I gave them a mixture of the strength of one grain of the extract of belladonna, dissolved in two ounces of distilled water; the dose was, for the adults, half an ounce, and under the age of fourteen, to vary from a dessert to half a teaspoonful, every morning, at eleven o'clock. The first dose was taken in the evening before going to bed. Mrs. —— was quite delirious and unable to sleep during the whole night; she declared her determination to take no more belladonna. The following day, after the second dose in the morning, a maid-servant, sixteen years old, was observed to be first asleep standing with one hand upon the mangle, and it required a violent shake to arouse her; when waiting upon her mistress she took the liberty to seat herself and drop asleep; when asked what was the matter with her, she thus explained the mystery,—"belladonna—it's all that belladonna." Every day, two or three hours after the medicine was given to this girl, she was thrown into a sort of trance and exhibited precisely the same symptoms. A boy ten years old was similarly affected; but although the whole family took the belladonna for the space of a week, no one else showed any very marked effect. Not one individual of this family had the scarlet fever. I could relate numerous striking instances of the prophylactic powers of belladonna, but I have no time to dwell further upon the subject. I am told Dr. Locock is in the invariable habit of employing it for this purpose.—W. BAINBRIDGE, Upper Tooting. [Neligan fixes the dose of the extract from gr. ss. to gr. iv.; Paris from gr. j. to gr. v.; Barry's extract is much more powerful than the common extract.—ED.]

O. P. Q. AND THE EDINBURGH UNIVERSITY.—That O. P. Q. is a very able man I have no doubt, whoever he may be. Your readers must, however, see that he is a sophist of the canine species—a cynic, so much so, that I fear he is capable only of that damnatory subdivision of the critical art. I think myself a brave man to run a tilt with a writer who can prove all to be "scoundrels and cheats" that differ from him, and who can be so heartless as to hurl his thunder on men who, "when they get to India, assemble and toast Dr. Munro and the University of Edinburgh." If we are to take O. P. Q.'s word, the University of Edinburgh is a "humbug" (bugs they say are common in Scotland), "the thing at the other end of the rail is below notice," and the University of London is "Stincomalee," because it is a "Scotch thing." Now King's College is on the same plan, plus a clergyman, who makes no great difference with such grey beards as young doctors. Every other medical school in London adopts the same mode of teaching the medical art by hospital practice, and by lectures chosen by patronage under one reserve, that the men be capable of the duties of their separate offices. O. P. Q. omits to say where "a father may send his son with some chance of a medical education." Now it must be remembered that we do find some men capable of practising the profession; and my first objection to O. P. Q.'s animadversions is, that he proves too much if he proves any thing, because the same remarks will apply to every other medical institution in the empire. Then, again, if all are in the same state, is it not fairer to begin our impracticable reforms at home, where most of our young men go for instruction? What a wonderful world this will be, when of patronage the universal voice shall say, "Down with it;" in other words, when men will not favour their friends; and what a wonderful system of instruction we shall soon have, when the sneers shall be justified which O. P. Q. has thought proper to cast on "lectures," "professors," "university students," &c., words which even to the man of forty years' practice suggest those instructive principles on which he would gladly again enter. I object again to O. P. Q. as a mere quibbler. The following shall be succinctly given as a specimen:—"The os hyoides," says Professor Munro, "is not immediately (except in a very few rare cases) connected with any of the other bones." We had thought, says O. P. Q., the "stylo-hyoid ligament a very constant bond of union between the hyoid bones and the basis of the skull, not always ligamentous, it is true, but still a constant bond of union." Here is a sophism on the word "connected." Dr. M. has been previously describing the connexions of each bone with the adjoining bones; he has not been describing ligamentous attachments; and, speaking of the os hyoides, he uses the expression above quoted. Now, did not O. P. Q. know from the context, that Dr. M. was speaking of osseous apposition? Is it honest to use such a quibble in a sober discussion? If in describing the bones at the commencement of a system of anatomy, designed for beginners in that science, one were, instead of quietly describing the bones and their apposition, or connexion with each other, as the groundwork of the human frame, to describe with each bone the various ligaments, and so premise and embarrass the science, and darken the mind of the learner, by details unconnected with the osseous system, I have no doubt that "a stone would fall down from Jupiter," and the author of such a book would be "dubbed," a "fat-headed blockhead," a "scoundrel," and a "cheat;" but I ask, in common honesty, on whom these names most fairly fall—on the man who gives a correct description of a thing, or on the man who distorts that description, in a public work, and, giving six lines unconnected with the context, distorts their meaning into what he knows is not their meaning, and then, edging his prevarications with no moderate quantum of national pique, holds up the author, and one of the first of institutions, to the contempt of the profession? I have not at present access to the work of Professor Munro, but I reason in the following manner respecting all the other hard things said by O. P. Q. The quotation above exposed proves error in the statement of the case against the University of Edinburgh, and that error arises from one of two causes, dishonesty or extreme inattention; in either of which cases the rest of that jumble of abuse is worthless, either as evidence or as argument; inasmuch as, were it a labyrinth ten thousand times more intricate, it may, perhaps, need only a similar clue to unravel it. A solitary quotation here and there, made by such a writer, and without the context, is to be received with the greatest distrust. It is also possible that the work in question may, like all other works, have some few errors, "*nemo sine vitiis*, &c. &c. To write, to publish, to be *reviewed*, are elements forming a chain of events that happen to every author, and the last of which is sure to be disagreeable, if the reviewer is determined to make it so; and that such is the misfortune in the present affair can be proved, if from nothing else, at least from this: the reviewer tells us a number of incredible things, and winds up by saying, that a "student" told him, &c.—presuming that an enlightened profession will look upon that as evidence! I shall not "beseech the reader" to examine O. P. Q.'s theatrical exhibition of Dr. M.'s allusion to the pericardium. The reader must have seen through it. We are all aware that the heart has a covering of its own closely adherent to its outer surface, and that, strictly speaking, the heart is in that covering. In common loose phraseology, we speak of the abdominal cavity, and of the organs contained in that cavity, but, in point of fact, none of the viscera are in the abdominal cavity, as the peritoneum is only reflected on the outer side of each organ or viscus. The same is the case with the crucial ligaments, which every body knows are not in the cavity of the knee-joint—the synovial membrane, being reflected over every part of their sides, leaving them out of the cavity altogether. In the same strict and absolute sense the heart is not in the pericardium, but in its own membranous covering, which, reflected from the great blood-vessels, excludes it from the pericardium. Now O. P. Q. must have known all this, and could have expressed it in more succinct, certainly in more powerful language, but he was determined to "pluck" the University, in return, one would imagine, for some similar compliment, and he presumed to find our profession so fond of scandal, or so ignorant, as to receive a sophism. The reader will remember, that the quotation of O. P. Q. is not the only explanation of the pericardium in Dr. M.'s work, but is merely a concluding remark, made with the design of rivetting on the mind the anatomical fact which it involves. Then, again, Mr. Editor, one may fairly object to the test laid down by O. P. Q. of the merits of a University. The works edited for pupils must necessarily be elementary; in such productions you cannot look for any vast accessions to science. Medical professors in universities are no sinecurists, if they

properly attend to the duties of their chairs, and last, not least, to the extensive practice which able men generally obtain, and which, as teachers of a practical art, they ought gladly to embrace. First-rate works come from men of leisure; few men in large practice have time for them; still less men in large practice, with the additional onus of university duties. I object to book-making as a test of ability in medical professors. Their business is to study and to practise the most efficient method of transmitting to their pupils their own sound practical knowledge, and although, now and then, a first-rate work has emanated from this, as from every other university, it will, I think, be admitted that the professors who, neglecting this less dazzling duty, made it a system to seclude themselves, that they may bring out "some great thing" by way of advertisement, ought to be sent "*nudis dorsis regionibus lumborum*" to some such earnest man as O. P. Q. for an appeal to the only senses they can possibly have remaining. I think the University of Edinburgh has worked well on the only fair test by which it can be tried; all the leading men in the kingdom have been trained on this "Scotch system," either in or out of Scotland, and one half of them, more or less, in Modern Athens herself. I have taken the trouble to look through the pencillings and obituaries of eminent medical men, as given in the *Medical Times* for some months back, and I find those articles will justify the strongest expression that can be used on this part of the question. I shall not, Mr. Editor, presume any longer to occupy your valuable columns. You can have no interest but "to let the best horse win," and you will therefore admit this, or some better answer to the twin monster, which you have been called upon to introduce into this factious world. Scandal is generally palatable to human beings, but I think your readers are rather interested on my side of the question, for they are not the rough untutored "home," but gentlemen. I never was in any way connected with the University of Edinburgh, but I think I am not alone in the category of disinterested remonstrants against the article alluded to; and it will be a libel on the readers of the *Medical Times*, unless in its instructive volumes we see close at the heels of such a tissue of prevarication some exposure of its illiberality and sophistry.—J. D., Chatteris.

Cholera Morbus.—Since we were visited by that dreadful disease improperly called cholera morbus, I have seen every year a few cases accompanying the common bilious cholera. Within the last week I attended three as well-marked cases of Asiatic cholera as I have ever seen; each case presented the blue colour of skin, the distressed countenance, cramps, purging, and vomiting of a watery fluid, like whey. Two of those cases were persons whose constitutions had been injured by intemperance; but the third was a healthy woman, and, rather curious, I attended her for a similar attack this time two years, and each time she was quite well preceding the attack, which came on suddenly in the morning. I think it would be very interesting to learn the experience of medical men generally upon this disease, to know if others have found cases thus occurring every year, or whether it has entirely disappeared from some more favoured portion of our country.—Jas. M'Donagh, M. R. C. S., Sword's Dispensary.

Medical Assistants.—You, whose columns are always open to the cries of the distressed, and to the exposure of the abuses existing in any class of society, whose columns have been most ably devoted to the cause of medical reform and the advancement of the general practitioner, give space in them for the insertion of this letter from one of their assistants, and thus draw attention to their treatment of us, their "poor assistants." And when I draw the following picture of my own situation, there are, and you yourself, Sir, know it, hundreds—aye, I might say thousands—who are obliged (not content) to drag on a miserable existence under circumstances far less pleasant than those I am about to detail. I shall speak of myself alone, and I am, I believe, rather fortunately *fixed*. I am the son of a gentleman, and have received a gentleman's education, and have passed two years (after my apprenticeship), at one of the hospitals in London, attending lectures and hospital practice. At the end of the second year circumstances occurred which obliged me to seek for a time a medical assistant's situation, and then for the first time I became acquainted with the miserable pittances obtained by that class of unfortunate beings, from the medical agent whom I called on in the Adelphi. I told him (the agent) that I wished for a situation where I should meet with some of the comforts of a home and gentlemanly treatment. He told me I should find them all far from pleasant, and that whatever I had heard concerning the miseries and discomforts of such a life, I should find them fully realised. To make a long story short, he had, he said, on hand a situation which he thought would suit me, from the report of former assistants, and that I should find it as comfortable as such situations generally are. The salary offered was £25 a-year, to pay my own expenses down, which amounted to £3, leaving £22 a-year; and this a liberal salary, more than the average. For this miserable pittance, listen, Sir, to the list of my duties. Up at seven, and in my surgery, a miserable apartment, thirteen feet square, seven feet high, combining the double purpose of a dispensary and sitting-room, paved with tiles, and the sides ornamented with bottles; and, to prevent yourself from being suffocated with smoke, obliged to sit with a window open, and hence nearly *starved* to death with cold. My duties are, dispensing, taking messages, and visiting the poorer classes; the practice being extensive, and comprising two districts of two separate unions, and extending through fifteen or sixteen parishes, and attendance on various clubs, the day, as you may suppose, is pretty well occupied; riding from twenty to thirty miles a-day, three horses being kept to do the work; frequently called up at night, and at the pleasure of your *master* whether you shall go or not. As there are frequent *increases*, the disturbances to one's rest are not infrequent; so that from nine at night till seven in the morning, and from seven in the morning until nine at night, my mind is never free from the anxieties of my employer's business. Independent of all this, there is the care of the books and ledgers, and writing of bills, the delivery of them, and the dunning of the patients for money; the first not an agreeable operation, the last detestable. This, also, devolves on the poor medical assistant. Sir, does not this picture (and this is a gem compared to many) draw forth your commisseration. Ought not Sir J. Graham, whilst legislating for the general practitioner, to give a passing thought to the medical assistants. Cannot some means be devised for their better remuneration? Cannot their salaries be fixed by law, not to be under a certain sum?—in the same way as the salaries of the poor curates in the church are regulated. Let me, then, conclude by calling on the medical assistants to be up and stirring; let them lay their grievances before the public; and, if they cannot wring a more generous treatment from the hands of their professional masters, let them call upon Sir James Graham to do it for them. I write not this letter for myself, but for my fellow-assistants. A few weeks will, I trust, see me emancipated from this slavery, never more, I hope, to undergo the miseries and drudgeries of a medical assistant's situation. Let the medical assistants in London call a public meeting, and, if the practitioners of the present day will not meet their views, then let them appeal to the House of Commons, and, ere the present bill becomes a law, let there be some law to regulate the fair and just remuneration of that unhappy and ill-treated class of beings, of whom I have at present the misfortune to be one—A Medical Assistant.

The late Libel Case against the Medical Times.—Judging from your extract from "A Committee-man" in the last number, I am forced, on the principle of *ex pede Herculem*, to regret that you did not publish the whole communication. I agree with him that the intention of the donors of the "subscription fund" is not answered by your prize endowments. I subscribed as an expression of opinion *for* you, and *against* your *shabby* opponent, just to show that his action was an impost, not on you, but on the profession. Another of those jobs and bubbles,—now a college—now a journal—now an association, and now a legal action, by which he has so successfully pocketed the hard-earned money of medical men, *value not received*. For *you*, Sir, above all, *against him*, I would subscribe—for "prize endowment funds" I respectfully decline. Do I stand alone? While the one aim was before the public, what was the subscription in one week, by your own confession? Close on a hundred pounds! You thought proper to divert the aid tendered to a "prize fund," and the donations ceased forthwith. You have turned a public matter into a private question, out of a preposterous notion of dignity or pride. Had you any authority? No. My opinion therefore is, that the committee should meet, pay the expenses, and return the residue to the subscribers. For my part I did not subscribe my ten pounds to a prize fund, and don't intend.* And now, sir, while my hand is in, I'll venture an opinion on the trial itself. The *Standard* was right when it said, these sort of actions *in genera* are the actions of well-dressed pickpockets, unprincipled fellows who want to get money by due course of law without earning it by due course of virtuous industry. The law allows you to rob a church, or an orphan, if you are *not detected*; the law actually helps pettifoggers every day in the week to enormous injustices; and just give me a fair-looking, fair-speaking swindler, as badly off in character as in conscience, and if he'll only face public life and public infamy, I'll guarantee him by *law*, aye, by LAW, an easy income of £300 a-year. Do you know the secret? Actions for libel. Oh, sir, there is a fine livelihood open to a good trader in little actions. Pope says—

> It stands on record, that in Richard's times
> A man was hanged for very honest rhymes;

and it wants no Pope's authority now to fulminate the truth, that by the law of libel, as it stands, an honest criticism is a dangerous piece of literary impudence, and that any fellow in public life who will add to the infamy of a felon's repute the infamy of a pettifogger's legal larcenies, can earn his £300 a-year easily, *i. e.*, enough per annum by libel actions to escape the perjury of a false parliamentary qualification. Thus far, then, on general principles, I wholly agree with the *Standard*. And now, sir, leaving this digression with an apology for wandering so far from my subject, I proceed to say a word on your special case and your opponent. Has the letter of "Vindicator" been disproved? Has an *attempt* been made to disprove it? What did Judge Pollock say? That it was immensely clever! What does the plaintiff's counsel say? That it was published in a most extensively circulated journal. What is its burden? A series of accusations that must drive any ordinary character out of public life, if true. Well, then, thus clever, thus widely circulated, and thus intensely momentous, where is the reply?—where the vindication? What statement has been proved false? What inference unfounded? None; positively none! A medical politician has been arraigned and put on his trial; he has the public and the press at his command, and he has not a word to say for himself! His reply is, I care nothing for the truth or falsehood of Vindicator; all I care for is Vindicator's money. Mr. Healey was right, quite right, in retracting nothing—in apologising for nothing; in saying, "there stands the letter, charge for it what you please!" It was not the "clever and widely circulated" accusation that was on trial, but the accused, and he had no answer! He had not even the privilege such persons rarely want—a witness to character! Who, Sir, forgets the affidavit that removed the trial from the sheriff of Middlesex to the court of the late M.P. for Huntingdon? It was sworn that the change was necessary, because there would be put in evidence publications involving the settlement of nice points of law; the trial came, and where were these publications? The affidavit had served its turn. But the process promises to have the termination that all such trickeries so well call for. If well informed, the respectable plaintiff will not get the miserable £150 the jury gave him, without another trial. So conclusive, I am told, was the evidence of a judicial misdirection, that Baron Platt has allowed you to move the court for a new trial.

---

* Our correspondent may have his subscription by applying at the office. Of course our proposal of prizes was always meant to be subject to the approval of the subscribers.—Ed.

When that event comes off, it will be interesting to know how much cash the *distinguished* plaintiff will receive, after all, as his recompense for standing in the public pillory, in which he (*more* than *you*) has impaled himself.—E.

UNSUCCESSFUL ATTEMPTS AT MEDICAL REFORM.—In a recent number I find the following observations:—"At the close of the session, after twenty years of tricky nonsense, the order-paper of the House of Commons contains a long notice of a bill on medical reform from that notorious Marplot of good medical legislation, Mr. Wakley. It is needless to say that the manœuvre is transparent, and that this attempt to hoax medical men and the public will be no more successful than the mock project of a College of Medicine, the hollow support of a British Medical Association, the grand bubble of a Medical Protection Assembly, and equally deceptive scheme of an Aggregate Meeting and Breakfast." Nothing can be more true than this description; but might you not have added, that while everything he has supported has been ruined, everything he has opposed has been saved, *ex. gr.*, the hospitals, University College, the College of Surgeons, the Apothecaries' Company, and, finally, the National Association? One wonders at the persistance of some public nuisances, which, the worse their odour, the more they push themselves under people's noses. I finish briefly, Sir, for the shorter these sort of literary executions, the better.—OBSERVER.

GOSSIP.

ROYAL COLLEGE OF SURGEONS.—Gentlemen admitted Members on Monday, August 11, 1845:—H. M. Cockerton, T. Eccleston, T. E. Eden, F. S. Tate, S. H. Fasson, E. Martin, T. Peppard, H. M'Carthy, J. Wallace, J. Bayly, W. H. Wright, G. T. Hodgson, J. Maund. Admitted Friday, August 15:—E. Waters, F. Collins.

The following gentlemen were admitted to the Fellowship of the Royal College of Surgeons of England on the 8th of August:—W. Peter Nichols, Frederick Harrington Brett, Edward Stephens, Richard William Spicer, George Lionel Fitzmaurice, Thomas Fereday, Thomas Storm Robertson, James Whitehead, George Warren Watts Firth, Richard Henry Meade, Martin Thomas Hiscox, Henry Savage, John Philips Potter, Nathaniel Ward.

APOTHECARIES' HALL.—Gentleman admitted as Licentiate on August 21, 1845:—W. Docker.

OBITUARY.—We regret to announce the death of Dr. Edward Octavius Hocken, of Bloomsbury-sq., one of the physicians to the Blenheim-street Dispensary, a gentleman well known to the profession by his contributions to the advancement of medical science.

The *Medical Gazette*, in a brief article, prompted by a need that suggests ingenuity, expresses its difference of opinion with us in the utility of the *Provincial Medical Journal* in relation to a political association that should have great public influence, *and eulogistically* expresses its "pleasure" that it will not lose "our contemporary *altogether*," and its hope "to see it continue its *quiet* and even course!" Is this satire in disguise?

Judge Pennefather, at the late assizes at Nenagh, ordered the medical witnesses two guineas a-day, instead of *one*, the usual fee. This may be considered one of the results arising from the combined exertions of the profession in placing their rights and claims effectively before the public.

A travelling dentist left his creditors, in a fashionable watering-place, the following cheering announcement on his door:—"Dr. M—— is *gon* to London *to atend* the *Roial* Family!"

The chemists and druggists are generally very opposed to Sir James Graham's new Medical Bill. They are anxious to have a law for prohibiting pharmacy to medical men, and fancy that if a delay take place for a year or two they will gain their object. They are promised aid in an eccentric quarter, where, without large pecuniary interest, they were least likely to expect it. The next session is to show something more astounding to the general practitioner than the attempts at dissension he has recently witnessed.

A SELECT PRACTICAL FORMULARY.

Translated from the French of M. Foy, Principal Pharmacien to the Hospital Saint Louis, at Paris.

(Continued from page 400.)

SOLUTIONS, OPIATE (Hôpital des Vénériens).—Solutions containing, No. 1, four drachms, and No. 2, eight drachms of gummy extract of opium to the pint of pure water, or one ounce for No. 1, and two ounces for No. 2, of crude opium to the same quantity of water. Mode of exhibition: Externally, to wash painful syphilitic chancres and ulcers.

SOLUTION, PEARSON'S.—A solution containing one grain of the crystallised arseniate of soda in the ounce of distilled water. Mode of exhibition: Twenty to sixty drops in the course of the day in a mucilaginous menstruum. It possesses the same properties as the arseniate of soda.

SOLUTION, SCUDAMORE'S.—A solution containing from thirty to thirty-six grains of alum in the ounce of common water, or rose infusion. Mode of exhibition: As a topical application, or in injections in arterial or uterine hemorrhage.

SOLUTION OF SAL AMMONIAC (Ricord).—Two drachms of sal ammoniac dissolved in eight ounces of pure water. Used as a topical discutient in the treatment of buboes.

SOLUTION OF THE SUB-CARBONATE OF POTASH (Rosenstein).—A solution containing one ounce of the sub-carbonate of potash in sixteen ounces of distilled water. Mode of exhibition: Twenty to a hundred drops daily, in a cupful of appropriate ptisan. Used in the treatment of rheumatism, scrofula, &c.

SOLUTION OF THE SUB-CARBONATE OF SODA (Trousseau).—One pint of hot water, to which from one to four coffeespoonsful of a saturated aqueous solution of the sub-carbonate of soda is added. Used externally in the treatment of pruritus of the external parts of generation in women. It is used three or four times a-day. *** The quantity of the alkaline solution is to be progressively increased until the patient experiences a burning heat, and the lotions should be continued for at least a fortnight after the entire cessation of the symptoms.

SOLUTION OF TARTAR EMETIC (Fontaneilles).—A solution containing one ounce of tartar emetic in sixteen ounces of distilled water. Employed in lotions or in frictions in the treatment of acute, but not very intense, cutaneous affections; also in simple phlegmasia, milk tumours of the breasts, intense headache, &c.

SOLUTION OF THE SULPHATE OF COPPER (Hôpital du Midi).—Four ounces of sulphate of copper dissolved in a quart of pure water, and filtered. A topical caustic and stimulant, to excite indolent chancres, and to dress moist pustules.

SOLUTION OF THE SULPHATE OF COPPER, CAMPHORETTED (Swediaur).—Four drachms of the sulphate of copper, two drachms of powdered camphor, triturated together, in two quarts of water. Mode of exhibition: This solution, diluted with water, is employed in injections, lotions, and collyria, as a styptic in traumatic hemorrhages, and as a stimulant in blenorrhagia, leucorrhœa, chronic ophthalmia, &c.

SOLUTION OF THE TINCTURE OF IODINE.—See Dilute Tincture of Iodine.

SOLUTION OF VERATRIA (Magendie).—A solution containing one grain of veratria in two ounces of distilled water. Mode of exhibition: One to four drachms in an appropriate menstruum. Used in the treatment of gout, chronic rheumatism, anasarca, &c. *** This solution may replace Husson's water.

SULPHUR OF ANTIMONY, GOLDEN.—Powder, one to two grains, as an emetic. Its sudorific powers are doubtful.

SULPHUR, SUBLIMED; FLOWERS OF SULPHUR.—Internally, as a purgative, one to three drachms in milk or honey; as a stimulant, ten to thirty grains two or three times a-day in the form of electuary or lozenges; as preservative of measles, two to three grains evening and morning, mixed with a little sugar. The same powder has been recommended to lessen the symptoms of measles, and to diminish the diseases which are caused by it, especially the cough. This plan of treatment, however, ought not to be adopted until after the inflammatory period has passed by. Lozenges (containing one part of sulphur lotum with eight parts of sugar) three or four daily.

Although sulphur possesses purgative properties, it is principally employed in medicine as a stimulant of the cutaneous system, either internally or externally, in the treatment of tetters, itch, rheumatism, &c. In acne it is given, combined with calcined magnesia, in the following proportions:—eight to twelve grains of sublimed sulphur, and the same quantity of calcined magnesia, mixed together; one such dose to be taken in the course of the day. It is also useful, as a general stimulant, in scrofulous engorgements, œdema, catarrh, and palsy, caused by mercurial or lead vapours.

The washed and non-washed sulphur is employed externally, mixed with fatty bodies, in the form of fats or ointments, or else in the state of gas (sulphurous acid) in appropriate apparatus.

SUB-ACETATE OF LEAD, LIQUID.—An astringent, very often employed externally as discutient and repellent, in the treatment of fractures, contusions, sprains, chilblains,[1] burns, &c. It is used daily in the hospitals to prepare the lotio alba, and the lotio vegeto-mineralis, which are employed in lotions to diminish the too free suppuration from certain wounds, &c.

SUB-BORATE OF SODA.—See Borax.

SUB-CARBONATE OF IRON.—Powder, one to three grains, mixed with the same quantity of sugar, given every three hours for seven or eight days, in the treatment of pertussis, accompanied by predominant nervous symptoms; ten to twenty grains, in bolus or pills, as a tonic or anti-chlorotic. (See Iron.) One to three drachms three times a-day, in honey, &c., as an anti-periodic in tic-doloureux, and other intermittent neuralgias. Four ounces, mixed with twenty-four ounces of water, in cases of poisoning by arsenious acid. A glassful of this mixture should be given every ten or fifteen minutes, after the patient has vomited, if the medical attendant has been called early in the case.

SUB-CARBONATE OF MAGNESIA.—Powder, half a drachm to two drachms, in a little water, in cases of gravel, dependent on the superabundance of uric acid in the urine. This sub-carbonate, which possesses the same properties as calcined magnesia, enters into the composition of effervescing drinks.

MORTALITY TABLE,

For the week ending August 16, 1845.

Causes of Death.	Total.	Average of 5 summers	Average of 5 years
ALL CAUSES . . .	864	901	963

[1] I have used it in gentle frictions on the tumours, when not ulcerated, in the dose of from one to two rachms evening and morning, and I have almost ways derived very great benefit from it.—M. FOY.

No. 311. SUMMARY. SEPT. 6.

CLINICAL LECTURES ON SURGERY.

BY M. F. LALLEMAND.

Translated for the Medical Times by JOHN WATERS, M.D. M. R. C. S. E., Ancien Elève des Hôpitaux, Membre de la Société des Medecins Etrangers, &c &c.

CASE.—*Venereal Disease re-appearing at the end of Twenty Years in the Mother—Showing itself at the Age of Seven in her Child—Different Modes of Treatment—Recovered by Fractional Doses of Gold Preparations and Sudorifics.*

Madame E——, of good constitution, menstruated at eleven years of age, and was married at fifteen; a year afterwards was delivered of a male child, who always enjoyed good health. The excesses of her husband induced her to leave him for a short period, and, on a reconciliation being effected, she shortly afterwards complained of severe pains and uneasiness about the anus. During a period of three months lotions were used, and an internal treatment pursued, at the end of which time she appeared well. Four years afterwards her husband returned, and until the period of his death he complained of illness: she, however, had four children, three of whom died from some obscure disease, the nature of which was not known. At the age of forty Madame E. complained of sore throat, which did not yield to the ordinary remedies, and was put under a course of bichloride of mercury and sudorifics, which effected a recovery. The fourth child enjoyed good health until he attained the age of seven years, when he frequently passed urine involuntarily during the night; became pallid and weak, and shortly afterwards many small ulcers came on the soles of the feet, which looked like chilblains, and only yielded to the application of an ointment containing red precipitate. From that period a state of cachexy came on, which was traced to a strumous diathesis, and he was accordingly treated for this affection. It was remarked that sea-bathing exasperated his symptoms, and that preparations of gold produced a manifest improvement. Subsequently there came on a painful swelling in the left fore-arm, which was ascribed to his assiduity and over practice on the piano. The pains increased, particularly at night. During four months and a half, different modes of treatment were ineffectually tried; symptoms of gastro-intestinal inflammation now appearing, they were supposed to originate from the employment of so many powerful remedies, and consequently their use was discontinued. It was about this time that the young lad was brought by his mother to see me. The left fore-arm was double the size of the right one, particularly near the wrist, and severe pain was felt in that part: he could make no use of the extremity, and the movements of pronation and supination were impossible: the nose was deformed, the ossa nasi sunk, and covered with large ulcerations, which extended to the palpebræ. There also existed great redness of the eyes, and photophobia; half of the eyelids of the left eye were completely ulcerated, and the palatine arch was perforated in nearly all its extent; the uvula almost destroyed; large and deep ulcerations covered the tonsils, the pharynx, the jaws, and the mucous membrane of the mouth; a polypoid excrescence completely obstructed the right nostril, which, as well as the mouth, secreted an abundant suppuration; a fissure made its appearance in the upper lip, extending from the nose downwards, and the ulceration appeared as if it would meet that on the gums. Having attentively considered the antecedent facts, I no longer doubted that the affection, which was considered to be scrofulous, was of a venereal nature, and my opinion was still further confirmed by the rapid improvement which took place in the ulcers by the use of bichloride of mercury.

It was particularly urgent to arrest the progress of the ulceration of the eyes, as an internal treatment could not be put in force from the severity of the symptoms; and I was obliged for sixteen days to contend against the progress of the disease by palliative means (lotions of the bichloride of mercury), which were not sufficient, as the venereal virus must be constitutionally attacked. Many methods of treatment could be tried, but I recollected that, under similar circumstances, the patient had once recovered by the administration of fractional doses of the preparations of gold, and I decided on giving them another trial. I merely added sudorific drinks, and discontinued the sublimate lotion, so that I might be enabled to judge what would be the effect of the treatment on the constitution. For fifteen days the frictions were continued on the tongue with five centigr. d'or divisé; for the next fifteen days the dose was increased to seven centigr., at the same time the patient took thirty gram. every morning of syrup of sarsaparilla, which was afterwards increased to forty-five, and then to sixty gram., and he drank during the day the "tisane" of sarsaparilla; this latter part of the treatment was obliged to be regulated by the susceptibility of the digestive organs, so that occasionally the sudorific measures were necessarily discontinued. It would be tedious to follow step by step the progress to recovery; but it is sufficient to say, that at the expiration of six weeks all the ulcerations were completely cicatrised, and the eyes were restored to their normal condition. However, the treatment was continued afterwards for two months, and at that time the left fore-arm had nearly obtained its natural size and the usual freedom in its movements. Twenty years have now passed away, and the recovery cannot be doubted—for with the return to health his intelligence was developed; and this once unhappy child, who appeared to be the victim of a certain death, has now become one of the most distinguished professors of the interior of France.

This case is interesting, not only in a pathological view, but it offers some peculiar points of interest in a physiological sense, such as the numerous disorders that visited this child in succession, and which were ineffectually treated by a host of remedies; we must not forget, also, the venereal virus which affected the parent, and which had been treated by local and general measures, and having lain dormant for a period of twenty years, at the cessation of the catamenia, again burst forth in all its intensity; nor should we forget that three children had died from diseases, the origin of which had not been ascertained by the medical attendants; nor that a fourth child, who was perfectly healthy when born, should only have presented the first symptoms of this affection when seven years of age, under the appearance of the so-called "*chilblains*," and which were cured by the local application of a mercurial remedy, to again appear later in life.

Here, then, is a case of syphilis which was reproduced in the mother twenty years after the antivenereal treatment, and which declared itself successively, without being recognised, in her four children, but in the case of the youngest, did not come on until he had attained his seventh year, although the parents did not offer any external sign of the venereal disease. Thus, the infection of the child is of a much later date than the apparent recovery of the mother, and came on long before the relapse she experienced. The child could not have been infected during the accouchement, consequently we must admit that the treatment of the mother had not been a radical one. However, whether the child had been infected by the father or mother *labouring under a constitutional affection*, it is very remarkable that they presented no apparent symptom of disease when conception took place.

CASE.—*Fatal Congenital Syphilis in Three Children, the Fourth Child cured by Antivenereals, although the Nurses had been changed twice.*

The Count de C—— contracted in the campaign of Jena a venereal disease, characterised by ulcers, which were situated on the glans. He attended to the affection during the war, and when the chancres were healed he paid no further attention to them. Two or three years afterwards he married, and, having consulted a surgeon, he did not consider it necessary to prescribe a fresh course of treatment, as there was no external symptom, nor any derangement in the general health that would warrant him to suspect the existence of a constitutional affection. Six months after his marriage, M. de C—— observed some excoriations about the glans, and ceased to cohabit with his wife. A short time afterwards, these excoriations having taken an unequivocally syphilitic character, he underwent an antivenereal treatment, consisting of sublimate, and sudorific tisanes, &c. About the same time Madame de C—— felt considerable irritation in the genital organs, then pain, which was accompanied with great heat and an ichorous discharge, which she laboured under for a long time without mentioning. The symptoms that she spoke of were attributed to pregnancy, and under this idea she had given to her several mercurial preparations, care being taken to conceal the fact. The inconveniences disappeared—the period of her accouchement drew near—and the treatment, which had not been rigorously attended to, now ceased. The accouchement terminated favourably; the child, healthy and fat, enjoyed excellent health until the fourth month, when he grew thin, his body was covered with pustules, and he died in the most emaciated condition two or three months afterwards. About the same time the mother's health became deranged; she lost her embonpoint; pimples appeared on the face; ulcers in the throat; a fresh antivenereal treatment was considered necessary. She now learned the nature of her malady, and punctually observed all that was prescribed (the

curial frictions, bichloride of mercury in solution, tisane and sudorific syrups). Repeated salivations came on; the hair fell off, and marasmus set in. The treatment was now discontinued at the end of three months. Shortly after Madame de C—— was confined, having gone her full time, and without accident. This second child began to droop about the fifth month, and died shortly afterwards, covered with spots and cutaneous eruptions. A third mercurial course was prescribed for Madame de C——, principally aided by sudorifics, particularly the "rob de Laffecteur;" the same disturbances occurred in the health as after the second treatment. A year later, a third child underwent the fate of the two others. Many consultations now took place, and the mother was considered cured; the infection which had proved fatal to those three children was attributed to the father, and in consequence he underwent a very long and very complicated treatment. Madame de C—— became pregnant some months afterwards for the fourth time, and was safely confined. At the age of four or five months, the child, which, up to that period, had been in good health, became covered with spots of the colour of the lees of wine, and accompanied with engorgement and induration, which was considered as of a scorbutic nature. Soon afterwards, pustules appeared at the child's anus, and the nurse's left breast was excoriated. I was consulted at this time; the child was seven months old; he was thin and pallid; the skin was flaccid, and the countenance emaciated. His health was evidently undermined by constitutional syphilis, and he had infected the nurse. The right breast was reserved for the child, and the nurse was cautioned not to allow the child's mouth to remain too long in contact with the nipple, and to wash it immediately after with a solution of sublimate (80 centig. to 500 gram. of water), to wash it again with milk before giving it to the child, so as to take away the disagreeable taste which the sublimate left on the skin; but the child refused the breast from the first day, in consequence of the application of the sublimate. The left breast was soon cured by the same lotions and the mercurial cerate; at the same time mercurial frictions were ordered, Sedillot's pills, a strong decoction of sarsaparilla, and its syrup in large doses. All the child's external symptoms disappeared by this treatment. A fresh nurse was now ordered, and about three months afterwards a fresh crop of pustules appeared at the anus; others came out on the tongue; the commissures of the lips became ulcerated; the same precautions which were ordered for the first nurse were recommended to the second. As to the child, he was treated by sublimate baths (from 2 gram. to 8 gram in 5 kilogr. of water), in which five or six spoonfuls of alcohol were added to make them of a tonic nature, and assist in the solution of the sublimate. After the sixth bath, the "fissures" on the lips were cicatrised. The nurse having now neglected the precautions that were laid down, observed, two or three days afterwards, an ulcer on the nipple. The child took twenty sublimate baths, and they were now gradually discontinued as the state of the skin improved; the child's strength increased by these means, and the little patient had become strong enough to be weaned. I should say, that the second nurse underwent an antivenereal treatment, of which the child had the advantage during the last two months of suckling. Although the state of health of this child now appeared perfect, an internal treatment was necessary to remove the remains of a constitutional affection which was so deeply rooted. Consequently, as soon as the child could eat, mild mercurials were administered internally, and these were frequently changed. Mercurial aphthæ appeared several times on the mucous lining of the mouth, with diarrhœa and some spasmodic symptoms. However, at the end of three months the recovery was perfect, and from that time nutrition became so rapid, that for many years the child was submitted to the strictest rules of diet. For twenty years the patient has continued well, without the slightest relapse.

But let us return to the mother. A fifth pregnancy took place, and the health of the child in utero was to be taken into consideration. Her vision was considerably weakened; her hair had fallen off; she had lost her embonpoint and complexion. These symptoms were ascribed by several medical men to the state of pregnancy, but I viewed them as the indication of a state of health which was still impregnated with the venereal virus. To protect this child from the fate of the others, it was necessary to attend to the treatment of the mother during her pregnancy; but we had now to decide, what the treatment was to consist of? The pills of Sedillot produced colic, which might cause a miscarriage. Corrosive sublimate produced gastric derangement, and I was obliged to abandon the idea of giving mercury, as it had been already administered under every form, and in considerable quantity, on former occasions. The hydrochlorate of gold, although there was little reliance placed in it by medical men at that time, was given, at first in doses of three milligrammes, and afterwards as much as six milligrammes. Under its influence no other remarkable change was produced on the economy, except a general excitement, an increase in the activity of all the functions, and constipation. The amaurosis gradually disappeared, the hair became as thick as formerly, the complexion of the highest colour, and her embonpoint gradually increased. Her accouchement came on; it was easy and regular; her treatment was discontinued for fifteen days, after which time she again took fifteen centigrammes of the hydrochlorate of gold, in the same doses as on former occasions, making in all thirty-five centigrammes, the amount of the preparation that was taken altogether. This last child was suckled by its mother, and enjoyed robust health, with the sole exception that, for a long time, it had a cutaneous affection, which the parents ascribed to the remnants of a venereal disease, but which I considered to be the result of the general excitement produced in the mother by the preparation of gold. In a short time this eruption, which was principally confined to the face, yielded to the use of simple emollients. Gradually the skin became healthy, and an obstinate habit of constipation also disappeared. The recovery was perfect in a few months, and has continued so. Three years afterwards, Madame de C. was confined of a very healthy boy, who never had the slightest cutaneous eruption. A girl was afterwards born, who always enjoyed good health from her birth. Thus, at length, this inveterate syphilis was entirely eradicated from the mother, who, after having passed ten years in the greatest misery, was now delivered from a scourge which seemed destined to embitter the rest of her days, and only to bring evil on those beings who were so dear to her.

We must not pass over in silence the consecutive accidents which visited the two nurses. We have just seen that the first nurse had been submitted to a long mercurial course. On her return home, she neglected herself, and was affected with an abundant salivation, and in a short time afterwards was delivered of a weak delicate child, which only lived a few days, and which, I understand, presented all the characters of a congenital syphilitic affection. However, the mother appeared to enjoy the most robust health, and had no symptoms of venereal disease; but she came to see me, and underwent a specific treatment. Fifteen months afterwards this woman was delivered of a second child, who died three months after his birth, and was covered with brown spots on the skin, and had pustules at the anus. Madame de C., who communicated all these details to me, said that the symptoms were exactly the same as those she observed in her own children. Although this woman appeared healthy, and although she had no disease ever communicated to her by her husband, with whom she always cohabited, it was evident that the venereal principle was not destroyed; consequently, she was submitted to the same treatment as Madame de C., and the hydrochlorate of gold was equally successful in this case. No accident occurred during its administration; it made little or no apparent change in her general health, and the child, which was born a month afterwards, never offered the slightest trace of a venereal affection.

The second nurse had an ulcer, which was communicated by the mouth of the child, and the energetic treatment was also put in force at the time, so that, from its effects on the economy, it was supposed that the venereal virus had been completely destroyed. However, at the end of six months, this woman felt uneasiness and heat in the genital organs, and she observed an abundant discharge, which marked her linen of a greenish-yellow colour. Three years after, I saw her, and found on the left labium majus a humid pustule about four centimetres in length, two centimetres in breadth, and elevated more than one millimetre. Some smaller ones surrounded the vagina and anus. These pustules were certainly venereal, and her husband never had the least excoriation, nor the slightest discharge. The hydrochlorate of gold was administered to her, as in the case of the first nurse, and it procured a rapid disappearance of these symptoms, which never afterwards reappeared.

The analysis of these cases presents us with a remarkable tableau in the great similarity which was observed among so many different persons in the principal features of the disease. We first see the venereal virus incompletely destroyed in the person of M. de C. by a superficial treatment, and that it remained latent in the economy for so many years, to burst forth again some months after his marriage, and to show itself in those organs that were subject to the most excitement. The wife then became affected, who was treated ineffectually, and we see the affection transmitted to her children, then to the nurses, although the disease must have lost some degree of its character by the several mercurial treatments that each had undergone; but it only yielded finally to the preparations of gold. Thus we see that the venereal virus *cannot be destroyed by new mercurial treatment*, for it would appear that the *system becomes habituated* more and more to its use, at the same time the disease is considerably modified by it, as it loses its contagious properties, as we have just seen in the case of the nurses, whose children died, however, of congenital syphilis. It is also worthy of remark, that the husbands of these two women never felt any inconvenience, although one of them had several pustules at the entrance of the vagina for two years.

THE STRUCTURE AND FUNCTIONS OF THE BRAIN, WITH NEW VIEWS ON THE NATURE, CAUSES, AND TREATMENT OF MENTAL DISEASES.

By M. PINEL, M. D., Member of the Academy of Medicine, formerly Physician to the Bicêtre, and Salpetrière Asylums, Author of the "Traité Medico Philosophique sur l'Aliénation Mentale," "Medicine Clinique," "Nosographie Philosophique," &c. &c. Translated, with Notes, illustrative of some important doctrines in Physiology, Phrenology, and Moral Education,

By Dr. COSTELLO, Principal of Wyke House Asylum, Editor of the Cyclopædia of Practical Surgery, &c.

Now we know the alterations of structure, the symptoms, and the progress of the disease, it will not be useless to cite a few cases of cure, in which, from an analogy of symptoms, an analogy of organic causes, ought to be admitted; that is to say, an œdematous infiltration of the cerebral tissue.

CASE 10.—Madlle. Rose ——, ætat. 24, of a strange, proud, and highly irascible character, was attached in 1831 to a young man, who promised to marry her; she waited the appointed day with impatience; this arrived, but the marriage was postponed. On learning this, Madlle. Rose ——, in violent excitement, broke her furniture and tore her clothes. "*She was not made to be played with by a man, she was a man also, and could prove it.*" This idea was so strong in her mind, that she took the dress of her new sex. On the 20th of October, 1831, she was admitted into the Salpétriére. She was then calm, and answered questions put to her slowly. Her appearance announced pride and disdain. All her other functions were normal.

On the 10th of March, 1832, she complained of a deep, dull pain in the head; she appeared less disdainful, but scarcely noticed the questions put to her. On the 28th her debility was extreme, she seemed neither to see nor hear; urine flowed involuntarily; had been supported by broths; the mouth gaped, and the general sensibility has diminished from day to day. If the eyelids are depressed, they remain so; the eyes fixed and dull. To remove constipation, three drops of croton oil were prescribed by M. Parisot; this produced several abundant stools, followed by a serous indolent diarrhœa, which continued for a week.

After this prolonged evacuation, a remarkable change was observed in the intellectual symptoms; she countenance recovered its natural expression; she asked for food, and in a short time recovered her perfect reason. On questioning her as to what she felt during her illness, she stated that she was conscious of her condition, but that she felt no grief, nor any wish to get out of that state; she felt no pain, still thought she was a man, but did not consider it of any importance. She left the hospital in perfect health on the 16th of May.

There can be no doubt, had she died during this illness, of some superadded affection, that a serous effusion would be found compressing the brain, and giving rise to that transient stupor, of which her symptoms were so strongly characteristic.

Case 11.—M—— a young man, son of a very irritable mother, was admitted into the Bicêtre, for the first time, in a state of mania, with predominance of fear, and religious ideas. His age was then fourteen and a half years. He was constantly invoking, and always in tears, "his sweet Jesus." Occasionally his agitation was such as to amount almost to convulsions. Antispasmodics administered in the form of enema, and baths, with affusion of cold water on the head, seemed to be particularly useful.

I learned that this first attack of mania had been caused by attempts at brutal violence being made on him, after he had been made to drink wine of cantharides. He left the hospital quite well in September, 1828; he returned in February, 1829, in the same state as before, and again left on the 23rd of the following April.

Another relapse occurred in January, 1830. He seemed to be threatened with demency. General delirium, countenance stupid, evacuations involuntary. This state, which began to be regarded as incurable, lasted several months, and suddenly ceased after the application of a large blister to the scalp; he recovered his natural gaiety and vivacity of mind.

One may judge of what he felt during his state of stupor by his answer to the physician, who had refused him permission to walk in the open courts of the hospital—"You restore my reason, and will not allow me to make use of it; I was happier when I was ill, for then I wished for nothing."

This is another of those frequent cases, in which a brain, already fatigued by two attacks of mania, experiences relapse, and presents symptoms progressively more severe. Both cases are important as regards the therapeutical indications. But Nature herself may sometimes suffice to restore the healthy functions. The following case will serve as an instance.

Case 12.—Maria L., a young needle-woman, ætat. 18, had the habit of drinking several cups of strong coffee at night in order to enable her to continue at work. She had but few hours' sleep out of the twenty-four, if sleep it could be called, which was more a state of dozing than a complete repose of the brain. On the 31st of December she had a violent attack of mania, in which she gave way to the wildest extravagancies—even to striking her mother, for whom she had the strongest affection.

I found her in the evening in a state of the fiercest exasperation. Next day she was sent to a Maison de Santé. After fifteen days of antiphlogistic treatment this patient became calm, and rational, and asked to see her parents. In the excess of joy her mother fainted in her presence. In the evening she complained of violent headache, her memory became confused, and utterance was slow and difficult. Eight days after the stupor was complete; she remained in the erect posture, walked but very little, and seemed to be alike destitute of ideas or desires. This lasted during January and February; skin dry and wrinkled, legs and hands slightly œdematous, and the stools sometimes involuntary.

On the 2nd of March, she was affected during the night with an abundant perspiration of a fetid smell, which was seconded by sudorifics. It continued for five or six days; the catamenia that had been suppressed reappeared, and convalescence began. Subsequently she had some active purgatives. The perspiration in this instance tending to free the brain from the serous congestion that compressed it, and coming on at the menstrual period, had all the appearance of a salutary crisis.

Case 13.—I attended the following case in company with Dr Belhomme:—

M. D——, ætat. 24, of a lymphatic, semi-scrofulous constitution, had been attacked six months before with mental derangement, marked by fits of violence and fury. General bleeding and a seton in the neck were attended with such good effect, that the patient was enabled to resume his occupations. Unfortunately the seton was suppressed too soon, and this was one of the causes of a relapse.

On the 7th of August, 1834, M. D—— was placed in Dr. Belhomme's establishment; his state was that of stupidity, accompanied with a degree of immobility and stiffness that rendered walking to any extent impossible. When placed in any situation, there he would remain until dragged from it by force, and the same difficulty existed in making him eat, get up, dress, &c.; he spoke but little, and only in monosyllables. His appearance was unfavourable; the countenance sallow and puffy, circulation languid, constipation. The setons were re-established, baths were ordered and purgatives. As the colour of the countenance became more florid, and the pulse became hard, he was bled. Being still in an unsatisfactory state in October, I proposed the use of more energetic purgatives. Croton oil was given in the dose of two or three drops. The patient improved, the immobility was not so great, and, what is not a little remarkable, he became abundantly salivated. In November he could answer questions fairly; purgatives were persevered in, combined with tonics. He had a strong decoction of coffee twice a-week, and two doses of purgative medicine in the intervals. During the two following months his progress was satisfactory; he could walk, and speak with facility. From being the prey of melancholy, he now began to occupy himself in drawing and writing long letters, which, though exhibiting some wildness of ideas, were in themselves, nevertheless, a proof of a more decided excitation of the organs on which the intellectual functions depend. This excitation, in fact, proceeded to such a length as to render bleeding necessary; the purgation was also continued, and at the end of a month he was so well that he was allowed a certain degree of liberty. After a treatment of seven months he was completely cured.

In regard to duration, we find that cerebral œdema is usually dissipated in the space of a few months; as to the treatment, the most active means may be had recourse to. The suspension of the sensibility, and of the nervous influence, will at once account for the tolerance of strong drastics or diuretics, as well as of the application to the skin of powerful irritants.

PHYSIOLOGICAL INDUCTIONS.

What application can be made of this pathological state to the explanation of certain functions of the brain?

1. *As regards the Intellect.*—Cerebral œdema produces on the brain an almost mechanical compression, by reason of which certain faculties begin to be disturbed, the intellectual disturbance increasing according as the serous infiltration penetrates into the interior of the brain; and, notwithstanding the stupidity, the patient retains the sentiment, the consciousness of his state, without having either the will or the wish to be relieved of it.

These results, which flow naturally from the positive facts we have narrated, may appear to possess some importance.

We should be entitled to conclude from them that memory, speech, and even will, are properties of the peripheral portions of the brain, but of both the grey and white substances, since the infiltration of the white substance renders the stupor still more general. At the same time, we must admit that the sentiment of perception and of consciousness belongs to the cerebral part of the brain, which retains its healthy condition in cerebral œdema, and thus leaves perception and consciousness intact in those patients. Facts of this kind confirm still more strongly the physiological truth, that each part of the nervous system has its own peculiar function and distinct properties. The pathologist, therefore, infers alteration of function from alteration of the parts, and reciprocally lesion of functions from the lesion of parts. On this point, too, anatomical observations are in complete accordance with the results of experiments. Thus, when Flourens saw the faculties enfeebled, and gradually extinguished, when he pared away the brain in successive slices, and when he passed beyond certain limits, that the abolition of the intellect was complete, he produced, by means of the scalpel, the same succession of symptoms that we observe in serous infiltration of the brain; and we must conclude, with this able experimentalist, that the most elevated phenomena of the understanding belong to the nervous centres of the encephalon.

2. *As regards the Sensibility.*—Œdema produces another peculiar lesion of the sensibility, distinct from that of the intellect and locomotion. The most remarkable phenomena of insensibility occur in the cutaneous system, the external mucous membranes, the conjunctiva, and in the nostrils and mouth; sometimes only partial—sometimes extending considerably. Here, again, cerebral œdema confirms the results of those experiments that have demonstrated sensibility and motion to be distinct properties, but that these properties do not reside alone in the nervous centres, as the external compression of the brain produces as decided an influence on the one property as on the other.

3. *As regards Motility.*—The symptoms as regards locomotion are more obscure and difficult of appreciation; there is numbness of the limbs, sluggishness, slowness of movement, but no paralysis in the strict sense of the word. The most remarkable symptom is the catalepsy observed in some of these cases. This is a lesion of the muscular contractility, transient like the lesion of the intellect, and totally different from that complete abolition of motility resulting from an internal laceration of the cerebral tissue, just as true demency differs from this intellectual stupor. Finally, œdema of the brain is an accidental complication of the chronic irritation of this organ in the insane, whose lymphatic temperament naturally predisposes more or less to serous effusions; but on account of its duration, peculiar symptoms, and the treatment it requires, it deserves to fix our attention.

III.

SIMPLE DEMENCY.

Demency is the general enfeeblement of the intellectual and moral faculties, in which all forms of incurable delirium terminate. It is characterised by absence of reason, oblivion of the past, and want of care for the present or future. This state has been long described as exhibiting loss of memory, profound apathy, absence of all desire, and incoherency of ideas and answers. Most of the insane, however, enjoy robust health; the organic functions are performed with fulness and force; they are voracious, lewd, and insatiable; they know neither fear nor affection; their whole appearance bespeaks a stupid tranquillity.

Senile demency is also the result of enfeeblement of the brain; it may attack, even in mature age, individuals whose constitutions have been impaired by disease or excess. In the same manner as after an attack of insanity, their intellect becomes gradually weak, memory disappears, the imagination is dulled, and they fall, like the insane or the aged, into a second infancy.

Pinel thus describes ordinary demency: "An alternating succession of isolated ideas, slight and contradictory emotions, inordinate movements and extravagant acts; total oblivion of an anterior state; abolition or diminution of the faculty of perceiving objects; obliteration of the judgment; inertness, or continued activity without object; wild and incoherent projects; oblivion of proper words to express ideas."

At a later period the symptoms become still more alarming; the patients can only articulate certain words with effort, sometimes only parts of words, the remainder expiring on their lips, as in their minds; the gait is tottering and uncertain; they support or try to support themselves by every thing that comes in their way; in walking, their legs bend under them, or they drag, and the slightest obstacle causes them to fall; their grasp, too, is uncertain, and they either let fall what they hold, or clutch it convulsively.

The countenance presents a singular mixture of astonishment, and an appearance of attention

without object; they look, listen, and answer without hearing or understanding; they shed tears on the most trivial emotion. At a later period, paralysis is superadded; the patients either pass the time in bed, or on a chair; the evacuations are involuntary, the limbs become contracted, gangrenous eschars are formed on all the points of the body bearing pressure, and marasm at last terminates this tedious state of disease; for it often happens that the progress and development of these symptoms will extend over a period of ten, fifteen, or twenty years.

We are not now speaking of demency complicated with general paralysis—the progress and symptoms of which are peculiar, and will be treated of in another place—but of common simple demency.

Are we to attribute the causes of this gradual annihilation of the intellect to any alteration of the brain? We are of opinion that there exists in this degenerescence of insanity an organic deformation, a species of slow induration of the cerebral substance, the characters of which we will now expose in the narration of a few cases. This alteration presents different degrees, both in demency and in complete idiotcy. In idiots, especially those in whom, as is often the case, a hemisphere is atrophied, the cerebral induration is quite manifest. The tissue of the brain is dense, elastic, and changed almost into fibro-cartilage.

In demency this induration, though less marked, is equally remarkable, as much in regard to its anatomical characters as to its coincidence and relation with the sinking of the cerebral functions. The brain, which in the healthy state is tolerably soft, and traversed by numerous and attenuated blood-vessels, becomes in demency in the long run entirely changed; the vessels disappear; the medullary pulp turns a dead white; it becomes hard, resisting, fibrous; in a word, it presents new anatomical conditions: I consider this induration as a peculiar disease, which alters slowly a part or the whole of the brain, and destroys its functions. Of this we shall now give a few examples.

A young girl, named M. Lenfant, healthy and strong, married at the age of 16, and in the space of eight years became the mother of five healthy children. During her last pregnancy her husband died, and through grief she fell into a melancholy delirium, which became more violent after the child was born. Admitted into the Salpetriére, on the 15th October, 1817; she was taciturn, refused food, avoided the company of other patients, and would not answer questions respecting her health; on other subjects her answers were correct, but short. In the midst of the puerile fears, vague terrors, and gloomy ideas to which she was a prey, her intellect seemed to retain an appearance of reason. For eighteen months the symptoms remained nearly the same. In the second year her memory began to be impaired, she spoke with difficulty, her countenance assumed a stupid expression. She continued to grow worse during the three following years. At this time her intellect was gone; and her limbs were paralysed. During the spring she became generally scorbutic, and died 25th May, 1824.

Autopsy.—Skull thin, uninjected; arachnoid healthy, pia-mater so closely adherent to the substance of the brain that they cannot be separated; the whole grey substance is pale, solid, and every where confounded with the white substance; the latter whiter than natural, and, as if covered with a brilliant varnish, is hard, solid, and resistant throughout the whole cerebral mass; this induration is still more marked at the base of the brain, in the optic tracts, and at the upper part of the ventricles. The brain is here so like fibro-cartilage as to resist the action of the knife, and "*cry*" as its edge divides it. So complete is this alteration that the cerebral fibres allow of being elongated, returning on themselves again by their elasticity, while in the healthy state any attempt of this kind would necessarily break up the brain. In the chest the left lung contains a large suppurating cavity; the intestines present numerous ulcerations.

Reflections.—In this case, sinister presentiments and incoherent ideas give rise, during eighteen months, to slight delirium. The intellect subsequently becomes more enfeebled, and, at the end of three years, the imbecility and paralysis are complete. Comparing the symptoms with the lesions, I should say that the adhesion of the pia-mater with the surface of the brain shews that a high irritation had prevailed there during the first eighteen months; that this irritation becoming afterwards chronic, and penetrating more deeply into the brain, begins at last to alter the cerebral pulp, which shrinks, and becomes discoloured, hard, and fibrous. The effect of this lesion is to annihilate intellect and movement. The scurvy, an accidental affection, is next superadded, and terminates life, which otherwise might have been prolonged for some years, as the induration hitherto had attacked but a portion of the brain. The affection of the lungs, as well as the intestinal ulcerations, were simply additional complications, depending one on the other, a condition often found in the last stage of demency.

Case 11.—Anne Montigny, ætat. 18, a young woman of strong constitution, had her side staked by falling on a sharp piece of wood, just over the ribs; there was a wound, through which, singular to say, the first menstrual discharge took place. The wound continued to reopen monthly to allow of this discharge. She married at the age of twenty-five, gave birth to a child, and the catamenia from this time took the natural course. About her fortieth year, she became unhappy, susceptible, was restless, cried without motive, and thought herself surrounded by enemies; six months later her melancholy gave place to furious mania, when she was admitted into the Salpetrière in 1815. She remained five months in this state, and became tranquil; but her memory and intellect were observed to fail daily more and more. She still lingered out seven years in a state of entire intellectual nullity, and, during the two last years, lost the use of her legs. On the 23rd of February, 1823, she was attacked with pneumonia, and died on the third day.

Autopsy.—Skull thin and white; membranes healthy; the brain has a peculiar appearance; instead of the usual furrowed surface, it seems flat and level; the convolutions, instead of being free, are stuck together, forming, over the whole surface, one compact rounded mass; a thin layer of grey substance seems to envelope uniformly the central mass, without dipping into any furrows. Internally, the whole white substance is changed into a solid tissue, entirely fibrous, especially towards the base of the brain. As in the preceding case, the cerebral pulp is torn into longitudinal shreds, possessing considerable elasticity. Both lungs hepatised at their base.

Reflections.—I recognise in the adhesion of the convolutions to each other, the inflammatory traces of an old-standing cerebral irritation, the cause of the first disturbance of the intellect; passing then into the incurable state, this irritation descends deeper, and during seven years, by a slow and gradual process, it alters the cerebral pulp, converting it into a fibrous tissue; the disorder of the intellect and of locomotion keep pace with the progress of the morbid alteration, and a prompt termination is induced by the attack of pneumonia.

We often see persons affected with demency attacked with furious mania for a period of varied duration, sometimes even periodically. Now, if after death we find in the same brain those acute and chronic alterations to which we attribute acute mania, and the other symptoms of demency, will not this fresh coincidence sanction with additional authority such inferences? The following case furnishes a striking example of this kind:

M——, a woman, had, up to the age of forty-five, enjoyed good health, although of delicate constitution. At this period, from domestic afflictions, she lost her reason, and she was admitted into the Salpetrière in 1809. She had a renewal of the attack of mania in 1810 and 1811, followed by a calm after a few months. These attacks were renewed every year till 1818. At this period her intellect, which had remained almost unimpaired amid these periodical shocks, became slow, sluggish; the memory became weaker, and she articulated with difficulty a few words; her whole constitution seemed shaken. During five years this state of demency became more and more alarming, and yet she had no attack of mania during all this time. In 1822 a fresh explosion of fury, accompanied by extreme restlessness, occurred; a fortnight after she became suddenly quiet, and in two days more she expired in a state of profound lethargy.

Autopsy.—Membranes of the brain both healthy posteriorly; in the frontal region the arachnoid thickened, opaque, uplifted by an albuminous exudation, adhering strongly to the subjacent substance of the brain. In this region the grey substance is of a deep red colour, disorganised and softened in several places. This redness and softening extend equally over the whole surface of the brain. Towards the posterior region of the two lobes there are several convolutions, entirely softened and reduced to a livid jelly. This inflammatory state of the whole surface of the brain, conferring a redness and softness not usual, contrasts most strongly with the whiteness and hardness of the internal substance, which, towards the optic tracts and corpora striata, are changed into an elastic fibrous tissue. The same was observed in the preceding case.

Let us now compare the results of the autopsy with the symptoms and phases of the delirium, and analyse them by means of each other. This patient presented two very different kinds of delirium: the one coming on periodically as furor, and retaining its intensity to the end; the other degenerating into demency, and a moral nullity continuing progressive to the end also.

I recognise the physical cause of the first delirium in the irritation of the surface of the brain—an irritation acute at one time, chronic at another, showing itself by almost regular attacks, and of which I take the long-standing and *chronicity* as demonstrated by the thickening of the pia-mater in the frontal region, and its inflammatory adhesion to the substance of the brain. I see, also, in the redness of the grey substance, and in the purulent decomposition of certain parts, the traces of the last attack of mania terminating in sudden inflammation of the brain, supervening on the fifteenth day after the attack, producing at first a calm, and then death two days later.

But while the surface of the brain was affected by a disease, giving rise to attacks of maniacal delirium, it became towards its base the seat of a contrary affection, a fibrous induration attacking in succession the central parts before mentioned, and sapping the functions of those parts, whilst externally the acute delirium continued in its primitive intensity; and it is probable that the state of demency would have become still more complete if the irritation at the surface of the brain had not, as in the last attack, terminated in a suddenly fatal inflammation.

This induration is also frequently found in epileptics, and in such cases explains the successive extinction of the different faculties of the intellect, the last stage of which is complete demency.

We do not, however, pretend to say, that all forms of demency are the result of such deformation: we know well the frequency in such cases of chronic inflammations of the cortical substance, of the meninges, and of the other lesions and alterations of the medullary substance; but we think we may take upon ourselves to say, that the species of induration here pointed out has b en but little studied, and that it has not been till now alluded to as a cause of demency. When the delirium becomes calm, and passes, in the course of a long series of years, into the chronic and incurable state, the red colour and inflammatory process going on in the grey substance, already described as appertaining to the acute stage, undergo a slow but profound modification. Altered, decomposed, by the stagnation of the blood, the cortical substance shrinks, loses its natural colour, becomes pale, and at last white, like the medullary substance, and undergoes an equally manifest induration. In this organic transformation of the brain, the intellect, as well as the other cerebral functions, keeping pace with its progress, from being exalted at first, become afterwards feeble, disordered, altered, and at last annihilated.

In the physiological point of view, demency forms an almost imperceptible transition from impotent delirium into imbecility; this period, like other forms of insanity, has its peculiar features; it is distinguished by fruitless efforts of memory, judgment, attention, and even by the consciousness of this intellectual decay. Persons in demency have a will, but cannot put it into execution; they have the con-

sciousness of the impotency under which they labour, and this distressing feeling vents itself in continual complaints and lamentations; their faltering and incoherent ideas escape in torrents of half articulated words. The intellect seems to struggle in vain against the disorder which is undermining it. When this struggle ceases, and they have lost the consciousness of their state, they lapse into imbecility.

PATHOLOGY OF EXPECTORATION.

By S. Wright, M.D., Edin., F.S.A.

Physician to the Birmingham General Dispensary, formerly Senior President of the Royal Medical and Royal Physical Societies of Edinburgh, &c. &c.

(Continued from page 426.)

Sectio-Cadaveris.—The body was excessively emaciated. Old and very firm adhesions were found at the summit of each lung, and more recent adhesions at the lower part of the right lung. Cavities were found superiorly in the lungs, of large size, and smaller ones were observed in other parts of the pulmonary structure. These cavities were all lined by very dense, even, and shining membrane, which, in a few places, was coated with purulent matter, but, in the majority, with clear and pure mucus. The pulmonary tissue was consolidated around these several cavities, but it had not any appearance of inflammation. One or two cavities were found in the right lung, slightly puckered, but quite smooth and dry. This lung was very emphysematous at its lower portion, especially along its border, and was thickly set with tubercles, some miliary and cartilaginous-looking, others cheesy, but tolerably hard, and quite dry. The left lung was emphysematous in places; some of its bronchi were dilated, and others flattened. It contained a great number of distinct miliary tubercles, hardened or semi-petrified, but no matured or softened tubercle. The heart was large and flabby, and its parietes thinner than natural. The stomach was unusually distended, and marked with slight patches of vascularity, as also were the intestines. The glands of the latter were hypertrophied in places. (He had been in the habit, some years before his death, of taking large quantities of Morison's Pills.) The right kidney was nearly double its natural size, though not unhealthy-looking; but he had often complained of pain in it. The dura mater was not vascular, but was strongly adherent to the cranium. The arachnoid and pia mater were natural. The surface and substance of the brain were much congested, and at its base about two and a half drachms of serum were found. Three and a half drachms of similar fluid were obtained from the fourth ventricle. Imbedded in the substance of the left optic thalamus, was a rounded mass of tubercle the size of a small hazel nut; the cerebral matter immediately in contact with the tubercle was of the consistence of cream. Beneath, and a little externally to this tubercle, was another, the size of a large pea. In the left lobe of the cerebellum two tubercles were found, one the size of a pea, the other double its dimensions. They were immediately surrounded by what appeared to be softened brain, such as was described in the first instance. A fifth, the size of a filbert, was discovered deeper seated, being just above, and a little to the left of, the medulla oblongata; and contiguous to it a sixth was found, the size of a large horse-bean. The medulla oblongata, and commencement of the spinal cord, were softer than natural.

In this case, it was clear that tubercular deposit in the brain arrested a similar deposition going on in the lungs; and the patient, instead of dying of phthisis, as he had every appearance of doing at the commencement of his illness, died of apoplexy, the consequence of irritation and pressure from foreign matter in the brain.

When consumption, which has advanced to the formation of cavities in the lungs, is arrested and superseded by tubercular, or other disease of remote organs, as in the example just recorded, or when, without the accession of mischief remote from the lungs, the progress of this phthisical degenerescence becomes suspended, or totally suppressed, we may safely conclude that the change is exclusively due to natural causes. At least, I know of nothing in pathology or therapeutics that could justify the inference that any such course of events could be attributed to treatment. It is a fact that we hear of "consumption curable," no matter what its stage; but this is the outcry of charlatans and quacks, and is deserving of no recognition amongst honest or enlightened practitioners. But it is possible, in the early stage of phthisis—that is, when miliary tubercles only are present in the lungs—for the progress of the disease to be arrested for a time, or permanently checked. And, indeed, instead of such cases utterly defying remedial measures, as advanced phthisis does, they generally respond more or less encouragingly to rational treatment. If they fail to be relieved or restored, it is either because there is a constitutional depravity which renders medicaments useless, or these have not been of the most salutary kind, or they have not been applied with sufficient promptitude and continuance.

The general treatment which has been found to be most successful consists in change of air, and the administration of tonic and alterative remedies. Situations should be chosen for residence which are mild and little varying in their temperature. They may be inland or marine, according to the feelings of the patient, and as either one or other may agree with him. As much exercise as he can comfortably take in the middle hours of the day, early rest and rising, with diet adapted to appetite and circumstances, are the chief things to be observed. If the bowels be constipated, mild aperients should be given regularly. The vegetable tonics are most to be preferred; they generally agree better than others with the stomach, and are less likely to excite or to augment fever. I give them with an alkali, carbonate of potash, or soda,[1] whenever it is practicable to do so, for the gastric irritation from which consumptives are apt to suffer, is almost invariably connected with an undue secretion of acid in the gastro-intestinal canal. In more advanced phthisis, the profuse night-sweats often compel us to substitute for an alkali a mineral acid. It is with great reluctance that I ever make the change, for with the exception of arresting the perspiration, I have never known a mineral acid to render consumptives the least service, and the cases are generally hopeless which call for its administration. They may sometimes be dispensed with by the use, in the morning, of sponging with tepid salt water and vinegar. In commencing phthisis, hydriodate of potash has frequently been found beneficial. It is best given with alkalies and vegetable tonics, in small doses, and long continued. If administered without an accompanying alkali, it is pretty certain to disorder the stomach in consequence of the decomposition which it sustains in meeting with the acid secretion of that organ.

Expectorants, sedatives, narcotics, and demulcents, are remedies for symptoms only, and contribute but little to a patient's cure.

The local means to be employed are depletions and counter-irritants; the former are indicated when any signs of pulmonary inflammation or congestion present themselves. The frequency with which these occur, and the necessity for correcting them, we have already commented upon. Blood should be abstracted by leeching or cupping. The best counter-irritants are croton oil, turpentine, and the volatile oils, tartarised antimony, tincture of lytta, and tincture of iodine. But these applications are of little use unless long continued, for which reason they should be employed of sufficient strength to excite constant itching or irritation, without at the same time producing blisters or pustules. These give rise to more inconvenience and sympathetic excitement than is compensated by any good they do, and, if persisted in, they often produce fearful debility. The object should be to obtain, not a severe, but a permanent irritation. I have always found it most serviceable to establish a counter-action over the immediate seats of mischief, and not to carry it all over the chest, as is sometimes done. I visited, the other day, a case of incipient phthisis, in which the tubercular deposit was confined to the summit of the left lung; in other parts the organs were in a healthy condition, and gave no evidence whatever of any tendency to tubercular degenerescence. The poor fellow's chest, however, had been assiduously besmeared over its entire extent with emetic tartar ointment, and a few more dressings would have covered him, from clavicles to diaphragm, with pustules. We should establish as much counter-irritation as may be necessary, and no more, for it is never obtained but at some sacrifice of constitutional strength. The degree of dilution which the local irritants may require, will, of course, vary with the subjects treated. Some people can bear very strong applications to their skin, and others are affected much more easily. When not using tincture of iodine as an external remedy in incipient phthisis, I invariably incorporate, with any other counter-irritant, hydriodate of potass; it not only assists the local action, but being absorbed, it often contributes most serviceably to a constitutional improvement.

One other suggestion I would offer is, that phthisical patients be always cautioned against swallowing their sputa. From motives of delicacy, and from the inconvenience or difficulty which sometimes attends exspuition, the matter which ought to be ejected by the mouth is passed into the stomach. When we consider how filthy and putrescent this matter usually is, we need not be surprised that serious mischief often follows its ingestion.

[1] "Soda has been given with apparent advantage in pretty large doses, at all periods of the disease; and some benefit was derived, in my own case, from the long-continued use of the supercarbonate of potass, or seltzer water."—*Young on Consumptive Diseases*, p. 68.

AN ESSAY ON THE VARIOUS FORMS OF ASPHYXIA, OR SUSPENSION OF SOME OF THE PRINCIPAL POWERS OF ANIMAL LIFE, WITH GENERAL RULES FOR RESUSCITATION.

By Dr. Chas. Clay, Piccadilly, Manchester.

ASPHYXIA FROM SUFFOCATION

May arise either intentionally (this being a common mode of suicide in France), or from accident, by inhaling noxious vapours; choking and hanging are species of suffocation. In these cases the head and face are much swollen; eyes protruding; tongue thrust out on one side; jaws often firmly closed; face livid; lips blue; abdomen distended; insensibility, &c.

Causes of Asphyxia from Suffocation may be twofold. First, mechanical pressure, or noxious exhalations, producing spasm of the muscles of the throat, consequently, constriction of the air passages and stoppage of respiration; secondly (as in hanging), outward pressure, preventing the return of blood from the brain, whilst the access of blood is undiminished, producing compression of the brain, lesion of its vessels, insensibility, &c.

General Observations.—All cases of suffocation have a strong analogy to apoplexy. Among the noxious vapours most commonly producing this species of suffocation and asphyxia, are the choke-damp of coal-mines, wells, caverns, &c.; carbonic acid gas, arising from fermentation in the manufacture of cider, perry, malt liquors; lighted charcoal; burning brick-kilns, lime-kilns. Want of free ventilation in apartments; hence death from this cause is common in Russia, in consequence of their mode of heating apartments by stoves. It is remarkable how long the body of an asphyxiated person, from this cause, retains its heat; I have seen this illustrated many times among coal-miners, well-sinkers, &c.

What should be done.—Evidently the first thing is to remove the body out of the influence of noxious vapours (if any) into a purer air; secondly, remove everything acting as a mechanical pressure on the organs of respiration. In hanging, do not forget to remove the cord, as I once witnessed an attempt at resuscitation with the cord still round the neck; and had I not arrived at the very moment, it is needless to say how vain the efforts at restoration would have been. Windows and doors must be opened; the body placed in a sitting posture; the chin a little elevated, neither allowed to fall on the chest nor to be thrown on the stretch

backwards. The body should be covered with blankets; face sprinkled with vinegar; chest sponged with vinegar and water, and blown upon; vinegar and water injected into the stomach, and given in clysters. From the fact of dogs being recovered from the effects of noxious vapours by immersing them in cold water, the practice of cold bathing to the legs may be tried with hope of advantage. The above means are particularly applicable to cases arising from noxious vapours; to which may be added, acidulated drinks for some days after restoration. This species of suffocation, as well as cases arising from hanging, may require the general remedies of asphyxia already enumerated, as friction, stimulants to the nostrils, inflation of the lungs with warm air, electricity and galvanism, when they can be obtained. In inflating the lungs, it has been suggested (and would be very desirable if it could be procured) to add a little oxygen to the air used for inflation; but I am afraid the time required to procure the oxygen, as well as the necessary apparatus, would render the application next to useless. Less effectual means are of greater advantage, because easily procured. Perhaps bleeding is one of the most valuable means in cases of this description, particularly in suffocation from hanging, relieving the congestion in the vessels of the brain. Solutions of ammonia, &c., applied to the skin; friction with ointment or liniment containing camphor have both been highly spoken of along the spine. Raspail recommends the air for inflation to be impregnated with camphor or myrrh, the intention of which is to obviate all tendency to decomposition, as well as establish respiratory movements. After the signs of life are established, Raspail advises hot broths and strongly spiced liquids.

A few things that should be carefully avoided.—Do not crowd round the sufferer, nor attempt resuscitation until removed into purer air. Do not omit to strip the chest of its incumbrances; let it have free expansion.

ASPHYXIA FROM SMOTHERING UNDER BEDCLOTHES.

We smothered
The most replenished sweet work of nature.

It sometimes happens that children are smothered in bed by accident; even the most exemplary and tender-hearted mothers have been known, when overpowered with sleep (after, perhaps, long and anxious watching), to lie upon and smother their infants. The same is done by covering them up too closely with clothes. Dr. Collier mentions the common turn-up crib-bed as frequently causing this accident, the children being forgotten, and the bed turned up. Cats not unfrequently get into cradles, in their fondness for warmth, and lie upon the faces of children, and, by thus excluding the air, smother them. Children in this asphyxiated state are often restored, if found in time, by sprinkling cold water and blowing on the chest, and removing them into a current of air; nevertheless, if the case proves obstinate, all the means in the last chapter on suffocation must be put in requisition.

ASPHYXIA FROM HANGING.

This thought, but thought amiss, that of himself
He was entire proprietor; and so
When he was tired of time, with his own hand
He ope'd the portals of eternity.

It may be said that all cases of hanging requiring resuscitation are suicidal, as those hanged under the sentence of the law are not to have the benefit of resuscitation. It would be very difficult to hang a person, if the noose on the rope did not slip tight round the neck, and the body was thrown off quietly This is a sufficient explanation why so many are restored who have attempted this plan of suicide, being no adepts in forming the noose or applying it, and seldom throwing themselves off suddenly; thus they are said to have been hanging for a considerable length of time, whereas the air has neither been excluded from the lungs, nor (in consequence of the noose being made ineffectual) has the pressure been applied so as to produce rapid congestion in the vessels of the brain. I recollect, when an apprentice, I wanted a dog for dissection, and hanged one four times—each time he resuscitated himself; the fifth time, with a thinner cord and a better noose, I completed the poor animal's hard death. It has been long known that if an opening be made into the trachea, below where the cord passes round, hanging is of little consequence, because respiration goes on in the usual manner. Rope-dancers (or more properly slack-rope swingers) are in the habit of pitching themselves off the main swing, with a rope noose round the neck, but by having both hands in a certain position, grasping the rope in front of the neck, the lateral pressure is prevented, therefore, no congestion takes place; and by so placing the hands that the trachea lies unpressed between them, respiration is not in the least impeded. Hanging, as has been said before, is a species of suffocation, and, therefore, bears a strong analogy to apoplexy. In hanging, the fæces and urine are generally forcibly evacuated, and the penis is in a state of erection. Hanging has been abundantly proved (by those who have been resuscitated) to be a very easy death; but all agree that the return to a state of existence is a very painful trial, and the agony of deglutition, for a considerable time after, often elicits expressions of dissatisfaction at the efforts of restoration. The general appearances of persons hanged are—the head and face much swollen, of a red or purple colour; eyes suffused with blood, and protruding; tongue thrust out on one side; jaws rigid; lips blue, &c. On dissection, the blood-vessels of the brain are distended with blood, and the lungs collapsed.

Cause of Asphyxia from Hanging.—The cause has been much disputed. Some maintain congestion to be the cause; others, the exclusion of air from the lungs. Perhaps the truth is, that both are necessary, to a certain extent, to produce death.

Treatment necessary.—Provided there is no dislocation of the cervical vertebræ, there is a possibility of resuscitation, but if any dislocation exist, the case is hopeless; real death may arise from three causes:—1. Exclusion of atmospheric air from the lungs; 2. Distention of the vessels of the brain, as in apoplexy; and 3. Pressure on the spinal column, by the dislocated vertebræ. It is evident, the first thing to be done in a case of hanging is to cut the person down, the second to remove the pressure of the cord. Bleeding as soon as possible from the temporal arteries or jugular veins, cupping glasses to the back of the neck. In bleeding, it must be borne in mind that extensive bleeding is not requisite; all that is wanted is to relieve the vessels of the head; if too much blood be taken, the vital energies may be too much prostrated. Friction, application of warmth, inflation of the lungs, and, lastly, electricity and galvanism; whilst resuscitation is being effected, the trachea should be pressed by the fingers into its normal figure and situation, as well as the adjacent parts where the cord has pressed. These parts may require emollient fomentations and leeches; and as deglutition is difficult, as well as painful for some time after the powers of life are restored, it would be well to avoid giving very small quantities of liquid, inasmuch as it is more difficult to swallow a teaspoonful than a mouthful; also larger quantities render the necessity of swallowing less frequent, consequently less pain is produced. Continue exertions for a considerable time after, though hope may have fled. All the means applied under the head of suffocation are advisable here.

What should not be done.—Never leave the cord; never bleed largely; never attempt resuscitation if dislocation is evident; never leave the patient whilst any probability remains, rather continue exertions too long than give up too soon.

ASPHYXIA FROM DROWNING.

Oh Lord! methought what pain it was to drown!
What dreadful noise of water in mine ears!
What sights of ugly death within mine eyes!
Methought I saw a thousand fearful wrecks, &c.

General Observations.—Drowning may be esteemed another species of suffocation. The length of time required to drown varies considerably; in some half a minute would be sufficient, in others five or seven minutes, whilst pearl divers will often remain a considerable time under water without any immediate ill effects; notwithstanding which they are a short-lived class, should they escape drowning. In cases of drowning, it was formerly supposed that the lungs were filled with water; but this is a fallacy, and has often been satisfactorily proved by experiment, viz., drowning kittens in ink—a very small portion of the fluid, amounting to a few drops only, could be found in the lungs. The respiratory muscles are exquisitely sensible, and when water attempts to enter the receptacles for air, they are immediately thrown into action, so as to exclude water, except the first drops that caused the excitement. The lungs are found collapsed; the blood is sent from the surface, and occupies (more in proportion) the heart and large blood-vessels. It does not appear, however, that in this species of suffocation there is that analogy to apoplexy which is observed in other modes of suffocation, no paralysis being present after recovery, as in most cases of apoplexy. There is often a little water found in the stomach. I once witnessed a case of drowning of a full grown man, in less than a pint of fluid; the fact was thus: the man had been drinking out of the tap of a barrel of ale till dead drunk; he fell on his face; his nose got immersed in a small quantity of fluid in a hole in the ground, from which he had not power to extricate himself.

Causes of the Asphyxiated State from Drowning.—There is more or less congestion of the brain. This species of suffocation arises from the attempt of water to pass through the air passages into the lungs; the respiratory muscles are rapidly thrown into action; spasmodic constriction accomplished; of course respiration ceases, and asphyxia commences, the proximate cause being exclusion of air from the lungs.

What is necessary to be done.—Very few cases recover after fifteen minutes' immersion. The body should be carried forthwith to a convenient place—laid horizontally, head a little raised, and the body lying on the right side; the wet clothes immediately removed; warm blankets thrown over the body; warm bricks, or oven plates placed under the chest and calves of the legs; head covered with a cap, and whilst one or two persons are actively employed in rubbing the body under the blankets (on which has been sprinkled plenty of dry mustard, flour, or even salt), others should be employed in inflating the lungs with a large pair of bellows, the pipe introduced into one nostril, the other, as well as the mouth, closed; and when the chest is filled, a four or six-tailed bandage, the ends of which are crossed over the chest, by a little activity may be made to press the air out of the chest alternately with the bellows filling it, in a similar manner to the natural action of the muscles of expiration. No one should remain in the room but those actively employed, and all unnecessary crowding round the sufferer should be rigidly avoided. A fresh current of pure air should be admitted; stimulants applied to the nose; clysters of warm salt and water thrown into the bowels. In inflation, if the hydrogen could be increased it would be advisable, but how to effect it in time is the consideration; when capable of swallowing, warm stimulating drinks are necessary; the warm bath has often been advised, but its utility is questionable, as has been stated in the chapter on Infant Asphyxia—certainly dry warmth with friction is more likely to be successful; galvanic and electric shocks, provided they are moderate, are useful. It has been proposed also to inflate the lungs with warm air; this, like oxygen, would be extremely desirable if the proposers could ensure the means to be always at hand; mustard poultices should be applied to the hands and feet; lastly, provided the most convincing signs of real death do not appear, it is necessary to continue the efforts at resuscitation for four or five hours, and when recovered the patient must not be left alone for some time after. If it is certain that the person had previously been intoxicated, there will be a necessity for the use of the stomach pump, to clear the stomach from that which only adds to the difficulty of restoration if allowed to remain. In applications of electricity and galvanism, it has been proposed to cut down upon, and lay bare, a branch of the respiratory nerves or muscles below the seventh rib, as more effectual in restoring respiratory action; this is a proposition of great ingenuity, which is worthy of trial. Transfusion of blood is recommended, to which I have no objection, provided the blood used be human and the quantity very small, as there has been no previous loss, and too much might produce fatal effects by increasing congestion on the brain. In cutting down on the respiratory nerves there is no bleeding; but immediately on respiration being es-

tablished blood flows from the wound, which is rather beneficial than otherwise. Raspail says on submersion:—"Dry the body; then bathe it with the strongest camphorated spirits; the alcohol which passes by imbibition through the living tissues, removes from the blood the aqueous quality which it acquires from too long a stay in the water; now the circulation is arrested as much by excess as by deficiency of its menstruum. Also inflate the lungs with impregnated camphorated spirits." It is impossible to leave this important subject without pointing out a few things that are necessary to be avoided in cases of asphyxia from drowning.

Never use tobacco clysters, their narcotic? (depressing) effect is decidedly injurious; do not exhibit emetics even if the patient can swallow, as there is no water to eject. Never bleed in this species of suffocation as you would in hanging. Never rub the surface of the body with spirits, as their evaporation causes an increase of cold. Never attempt to pour liquids down the throat until there is a certain capability of swallowing. Never let the sufferer be held up by the heels, with the idea of letting water run out of the lungs or stomach. Never roll him on a barrel. It is absurd to talk of apparatus for the exhibition of oxygen, or hot air; of recuscitating cases of instruments, of electric or galvanic means; all of which are well enough if they can be procured, but, like the simple man who went to bathe without his floating belt, are found absent when most wanted. Far be it from my intention to depreciate the value of such means, because I know they are valuable; but I am convinced the majority of recuscitations are owing to the most common and simple means that can be procured. And why?—because they are at hand when wanted. I believe, therefore, the greatest good will be effected by teaching the world how to use (to the best advantage) those means they can understand, which are in their power, and at command, rather than distract their attention with the use of means it may never be their lot to employ, and which are difficult to manage.

ASPHYXIA FROM WOUNDS.

His wounds gaped horribly!

General Observations.—This has already been treated on in the chapter on asphyxia from hemorrhage. It is, however, necessary to notice it here, particularly as it is of consequence to bear those parts in mind on which wounds are most likely to be fatal, and which produce the asphyxiated state rapidly; this of course depends on the size of the vessel or vessels wounded. Hence wounds about the neck, chest, arm, and thigh, are likely to sever very large vessels, requiring surgical skill and anatomical knowledge to secure them. We must also remember the greater danger attendant on arterial than on venous hemorrhage; the arteries, being deeper seated, are generally more difficult to get at and secure, and the blood of a bright florid red colour, pouring out with great force and in alternate jets regulated by the heart's action; hemorrhage from the veins is more superficial, less forcibly ejected, coagulates quicker, and is of a dark purple red colour; lastly, it is more easily controlled. It must also be remembered, that the size of the wound does not always imply the extent of danger; a small wound may be very dangerous, wounding an important vessel; whilst a large one may be trifling, separating only small trunks. Wounds of the brain, even, are not always fatal.

What is necessary to be done.—The hemorrhage must be arrested; simple means, with presence of mind, will do much, till assistance can be procured. I once knew a very delicate female hold together a very extensive and prospectively fatal wound for upwards of an hour, when more efficient assistance relieved her from the onerous task. Holding the lips of the wound firmly together, or applying pads or cushions of linen on the parts, securing them with tight bandages, or, if a jet of arterial blood issues, a small hard roll of linen pressed hard upon the part, or the tip of the finger boldly and determinedly placed upon it, letting it remain till assistance arrives, is nearly all that one person can be expected to accomplish. The case, then, resolves itself into one of asphyxia from syncope, and it is necessary, therefore, that others should be employed in restoring the person, by the rules laid down under that head, whilst the hemorrhage is arrested.

What must not be done.—The wound must not be left; the pressure must not be removed, else hemorrhage is renewed, asphyxia returns, and the patient really dies.

ASPHYXIA FROM BLOWS.

The sudden effect of blows, falls, &c., in producing the asphyxiated state is remarkable, and often the internal lesion is so great as to render recovery impossible, as, for instance, in strokes of lightning, or falling from heights; still we are not warranted in leaving the case without some attempts at restoration.

What is necessary to be done depends on the nature of the accident. For the effects of lightning I have already provided in its proper place; in blows, falls, &c., bleeding is mostly required, and the common means of asphyxia generally, as pungent stimulants, inflation of the lungs, friction, &c.

What must not be done.—The person must not be left to perish without an attempt to save him.

ASPHYXIA FROM CHOKING.

Vitæ mors venit, aut victoria læta.

As choking is very decided suffocation, it may be considered as already treated on; but there are a few particulars necessary to be added to this species of suffocation not called for under other circumstances.

Cause of Asphyxia from Choking.—This arises evidently from objects mechanically obstructing the air-passages, by pressure, in the attempts to swallow them; but it may also arise from smaller objects, not of sufficient size to cause obstruction, but producing spasm and constriction of the air-passages by their irritation; the latter is quite as frequent as the former.

What is to be done.—To remove the exciting cause as speedily as possible. If within the reach of the fingers or forceps, to be drawn up; if not, to be thrust down with a probang; a common leek-stalk will be an excellent substitute, or even a common candle. Excitation of vomiting; a smart blow with the flat of the hand upon the chest, whilst the other hand is held firmly against the back of the chest, will very often cast out the obstruction forcibly, if well managed. This is an improvement on the old remedy of hitting the back suddenly. It is supposed to act by inducing a violent expiratory movement; the larynx being closed, an effort of vomiting is attempted, which removes the substance. The plan would be still more effectual by confining the abdominal muscles by pressure at the moment of the blow; for instance, if a child, the belly part might be pressed between the knees, the back held steadily with one hand, and the chest struck smartly with the other. As a last resort tracheotomy must be performed.

What should not be done.—If the choking arise from a very small substance, producing spasm, care must be taken not to irritate the throat with feathers, straw, &c. When such irritation is desirable, the objects producing it must not be passed down the throat too far, as they cease to irritate when passed beyond the fauces.

ASPHYXIA FROM INTOXICATION.

A third drinks neither for the good of the body nor the mind, but to stupefy and drown both.

General Observations.—This species of asphyxia can easily be distinguished from apoplexy, and from other poisonous liquors, by the well-known filthy smell attendant on all drunkards.

Cause of Asphyxia from Intoxication.—Congestion of the vessels of the brain are the effects of the narcotic influence.

Treatment necessary.—Emetics of eight grains of tartar emetic, or half a drachm of sulphate of zinc, given immediately in a small quantity of warm water. If incapable of swallowing, the stomach-pump must be used, to clear it of its contents. Purgative clysters; bleeding from the jugular veins, or temporal arteries; head washed with cold water, æther, &c.; blisters to the head and stomach. The body should be in an easy posture; all tight bandages removed from every part of the body; free exhibition of gruels, toast-water, prison diet, and teetotal principles.

ASPHYXIA FROM EFFECTS OF POISONS.

Such soon speeding gear,
As will disperse itself through all the veins
That the life-weary taker may fall dead.

The treatment of all cases where poisons are suspected to have been taken, falls strictly under the province of the medical practitioner. Under all circumstances, the general observer cannot do wrong by endeavouring to clear the stomach of its contents by emetics of tartarised antimony, or sulphate of zinc; for an adult, of the former from five to eight grains, of the latter from a scruple to half a drachm. Purgative clysters. If opium be known as the article producing this state, care must be taken not to exhibit any liquid combined with acid, until the stomach is perfectly cleared of its contents, otherwise the narcotism may be increased by forming a new chemical combination with the opium. In all corrosive poisons, milk can be generally easily procured, and is never mischievous, and should be used as a drink to dilute the contents of the stomach. If acids have been swallowed, magnesia in milk must be given. If it is known to be the oil of vitriol, be careful not to give water, as the heat generated, when it comes in contact with the acid, would add to the mischief. If cantharides be the cause, give gum-water. In all cases, however, emetics are the first means, or the stomach-pump. These are all that a general observer can be expected to undertake, and they are enough, when properly used, until assistance can be procured.

ASPHYXIA FROM EXHALATIONS, EMANATIONS, &C.

The following brief condensation of remarks by M. Raspail will be sufficient in this place:—

Asphyxia by the Vapour of Charcoal and Acid Emanations.—Abundant lotions of the sedative water, so as to redissolve by the vehicle of the ammonia the congestions caused by the chemical action of the acid vapour. Constant frictions along the course of the spinal marrow and the abdominal region with camphorated liniment; insufflation of air rendered slightly alkaline with ammonia.

Asphyxia by Ammoniacal Gas, Sulphuretted Hydrogen, and other Basic Gases. Several frictions with camphorated or aromatic vinegar; application of camphorated spirits to absorb the aqueous portion of the blood, and to diminish its liquidity; acid lotions to neutralise the exaggerated effects of the alkaline vehicle, and to decompose the poisonous gases by precipitating their bases.

Acid Exhalations and Emanations; Marsh Miasmata.—In the new process of gilding by dipping, and in the manufacture of vitriol and other acids, the workman is constantly surrounded by an atmosphere of nitric or hydrochloric acid, which is absorbed through all his surfaces. The trades in which mercury is employed are perhaps less injurious than this. Mercury attacks the nerves—acids corrode the parietes of the intestinal canal and of the chest. The men should here take care to work only under low and glazed chimneys, and to be surrounded by free currents of air. They should also frequently bathe their hands with ammoniacal water, and wear a cravat impregnated with it round the neck, so that the mouth and nose may be constantly enveloped with a vapour capable of saturating the acid emanations, and neutralising their effects. A mask might also be worn in such cases, containing similar antidotes. Those who labour in sewers, and on marshy grounds, should adopt similar precautions, or employ *cigarettes* containing particles of chloride of lime. The smoking of tobacco, otherwise very *hygienic*, can here serve only as a vehicle and auxiliary to the corrosive action of the acids and the miasmata. Fires on the borders of marshy grounds purify the air, not only by decomposing the chemical principles of the miasm by the flame, but also by converting them into a saponaceous compound by the essential oil, and neutralising them by the pyroligneous acid which is disengaged.—*Physiology of Health and Disease, &c.*

The appointment of surgeon to Her Majesty's yacht, William and Mary, vacant by the retirement of Mr. Edwards, has been given to Mr. M'Cormick, the adventurer to both Poles, he having accompanied Sir Edward Parry to the north, and Sir J. C. Ross to the south.

ON THE PROXIMATE CAUSE OF TUBERCLE, AND TREATMENT OF PULMONARY PHTHISIS.

By J. H. TOSSWILL, Surgeon, Torquay.

Neither climate, food, or natural conformation, must be regarded as the proximate and exciting cause of tuberculous deposit; they only act as predisposing causes. Many occupations have, however, a proximate and exciting effect in the production of results analogous to those arising from the deposition of insoluble matter in the delicate organisation of the lungs. Such are the occupations of the dry-grinders, stone-sawyers, &c.

It has been already remarked, that climate is a powerful agent in modifying the functions of the organs engaged in the production of animal heat, by means (in conjunction with improper food) of stimulating one organ at the expense of another; but other circumstances produce *immediately* this condition of function, which, by climate, is induced by its long-continued action. These conditions are especially the result of *natural conformation*, or that peculiarity of organisation which may be said to be congenital, and which, in the majority of instances, is recognised as hereditary; thus we daily observe individuals in this country, where oxygen must be taken into the lungs in considerable quantity, in order to support a due amount of animal heat, with an organic conformation adapted only for the mildest climates. Individuals of this class will, therefore, be placed in circumstances closely resembling those of the Indian who emigrates to a northern latitude, and who rapidly falls a victim to tubercular consumption. Such persons may be said to be *misplaced* as regards the locality they inhabit. Born with an organisation suitable for the tropics, they are placed in an atmosphere of condensed oxygen; their occupations perchance are laborious, and they are compelled to consume much food to furnish carbon for the production of animal heat; the lungs become taxed with an amount of function beyond their ability; congestion, an ever-present cause of irritation, follows; incipient inflammatory action supervenes; tuberculous matter perhaps is deposited. The irritation continuing, the inflammatory action likewise persists, and fresh matter is deposited around the primary nucleus. These bodies serve as additional irritants to the neighbouring parts; they inflame and secrete purulent matter, which, infiltrating the substance of the tubercle, cause its softening; finally, death puts an end to the unequal struggle between an organisation unfitted for its amount of function, and the causes imperatively demanding the full performance of it. Small lungs, congenital or hereditary, are one of the most frequent of the predisposing causes to consumption, and, under any circumstances, where a great amount of animal heat must be generated, or laborious exertions engaged in, the fact of being originally formed with lungs of inadequate dimensions, when placed in a position favouring the deposition of insoluble matter in the system, predisposes the individual to consumption. Suppose, for the sake of illustration, a person incapable of taking into the lungs forty cubic inches of air at each inspiration, whilst another can only inhale twenty, without the aid of external circumstances, such as increased clothing, additional protection, &c. If the two individuals have to generate the same amount of animal heat, in order to resist an equal loss of caloric, it follows that, with the lungs of inferior capacity, one man will have to perform double the number of respirations to oxydise the same amount of carbon; and with lungs only *half* the size, the amount of function will be *twice* as great, acting upon an organ only half as capable of enduring such function; and if, in addition to deficiency of capacity in the respiratory organs, we add a diminution of the capillary changes arising from a deficiency of blood-globules, and a disordered and congested state of the liver, we shall have these as additional causes predisposing to disease.

It is also evident that disease in one organ, out of many concerned in effecting the same end, must be attended with deranged function of all; thus, in the exanthemata, the functions of the skin being interfered with, there is an unvarying tendency to congestion and inflammatory condition of the lungs, the latter organs being compelled to an increased amount of function in order to compensate for the deranged condition of that of the cutaneous surface. In fevers, likewise, the capillary changes being especially altered, a constant disposition to visceral affections accompanies the disease—the result of capillary disturbance.

Any cause which naturally or artificially produces a condition of small capacity o the pulmonary organs, in a climate where a considerable amount of animal heat is required to be generated, must act as a cause inducing a modification in the organs engaged in the production of it. It matters not whether this arise from hereditary formation, or be induced by such circumstances as tight lacing, whereby the lower portion of the lungs, by compression, being rendered inactive and inefficient, the upper is compelled to perform the entire function; or whether, as a result of disease, by which a part of the lung may be rendered incapable of effecting those changes necessary for the evolution of heat, exacting from the sound structure an amount of function in equal ratio. In every instance the capacity of the organs so circumstanced is rendered unequal to the amount of function demanded. This capacity for organic results, it is however evident, may be relative as well as positive, arising from the condition of other organs engaged in the fulfilment of the same intentions. If the skin or capillaries, singly or combined, be inactive, a more considerable extent of function devolves upon the lungs—an extent, it may be, too considerable for an organ otherwise equal to the amount of function required. Again, if the liver be indolent and disordered, sufficient exercise must be taken to disintegrate organic tissue, to furnish an adequate supply of carbon to combine with the oxygen carried by the blood-globules. Supposing, furthermore, the skin and capillaries imperfectly to co-operate, the liver will be called into increased activity, and so long as it can eliminate carbon in sufficent quantity for combustion in the lungs, these organs (the lungs) will not suffer *directly* from a deficiency of that principle necessary to combine with the oxygen they inspire, but the liver itself will eventually become disordered by increased function if the causes in action be not removed. Lastly, if the liver and capillaries combined perform their amount of function inadequately to the demand for carbon in the lungs, the source of animal heat (carbon) will be cut off; the blood containing but few globules can oxydise but little of the metamorphosed tissue; this disintegrated matter not being secreted by the liver in the shape of bile, the lungs will either obtain but an insufficient supply of carbon to resist the loss of caloric, or they will have the whole function of supporting the animal temperature devolving upon their individual energies; the oxygen, which at each inspiration enters the air-cells, combining with and consuming the carbon presented to it in the course of the circulation in an imperfect and unprepared state. Such condition will prove a source of irritation to the lungs, and a cause of the consequent effects upon irritation; one organ having individually to perform the amount of function which should devolve upon many, increased motion of the pulmonary organs will occur, with increased waste and metamorphosis of the pulmonary tissue—whilst a deficient amount of nutrition will at the same time exist, the result of which will be local hyperæmia and a predisposition to tuberculous deposit, provided the immediate cause exists in the system.

Treatment of Consumption.—In deciding upon the character of treatment which should be adopted in cases of phthisis, the arguments which have been adduced in the progress of these papers should be *isolated*, and made the basis of it. These facts are, that—

1. Lime is the *exciting* cause of tubercle, arising from its abundant introduction into the circulation by the food we take; or from its deposition in an insoluble condition, from a deficiency of phosphoric acid in the system.

2. That climate, food, occupation, habits, and natural conformation are the *predisposing* causes.

3. That the predisposing causes act by setting up irritation and increased local function in the lungs.

4. That increased amount of function supposes increased motion in the organ producing it; that increased motion is attended with an increase of waste, and that an increase of waste requires an increase of nutrition.

5. That the food taken should be of a description calculated to support *two* purposes; first, the demands of nutrition—secondly, the requirements of respiration.

6. That in order to diminish the amount of function in one organ, engaged co-operatively with others in the performance of the same function, it is essential to withdraw the predisposing cause which has excited its activity, and to endeavour to increase the functions of the co-operating organs.

7. That the amount of capillary function gradually *diminishes* in consumption, by reason of the gradual disappearance of the globules of the blood; and that in order to supply carbon to the lungs, that of the liver must *increase*.

8. That animal heat is generated chiefly *in the capillaries* when the capillary changes can be properly effected, but that it is generated *in the lungs* when the liver has to prepare the carbon for combustion.

9. That exaltation of function arises from an increased demand for the results of such function; this condition requires an increased supply of blood, and hyperæmia supervenes.

PENCILLINGS OF EMINENT MEDICAL MEN.

PHILIP PINEL.

(Continued from page 306.)

It is now time for us to turn our attention to the most important period in the life of Pinel. The system of medical instruction in France had suffered the fate of all the other institutions, and, at the same time, the calamities of war had never before rendered medical services so necessary. In the midst of the disturbance into which France armed against Europe was thrown, three schools were created on the vastest plan ever conceived, except perhaps the Institute of Alexandria under the Ptolemies. The most talented men were chosen to form the school of Paris, and never before had so great a variety of talent been united. Pinel was not neglected, but was attached, with his friends Thouret and Cabanis, to this collection of eminent men. He was first elected to the chair of hygiene and medical physics, and soon after to that of pathology: the latter subject was, however, a serious source of uneasiness to him. Instruction was no novelty to Pinel; but to converse familiarly on geometrical truths so nearly related that they seem identical, and which are demonstrated more by figures than by words, was very different from the treatment of a complex subject before a large assembly—a subject which not only requires a plan, and distribution of ideas, carefully arranging each division, but also a flow of simple, clear expressions, always easily understood, and always varied in order to sharpen the attention and to keep the subject incessantly before the mind's eye. But Pinel did not possess this happy gift of expression, at least in public, his natural timidity being extreme before strangers. Besides which, perhaps, he had never considered in its whole extent the subject which he was to unfold before his pupils. What an inexhaustible field! Even in the division of internal diseases alone, what a multitude and diversity of objects! and, moreover, what mixture and what confusion! To engage himself and his hearers in this labyrinth, without first knowing its paths, was far from the nature of Pinel's mind, which was never satisfied with less than the clearest views of matters, and the strictest order they could receive. Former works did not supply this necessary order; they told him at the same time too much and too little. He could not adopt the hypothetical triple division of Galen's school, or that of Themison, so servilely imitated by the Solidists. In truth, that which Rhazes had done for the small-pox, Morton for phthisis, Mangold for tumours, ulcers, and apoplexy, which Mangold had himself conceived, and Felix Plater and Hebenstreit had attempted for diseases in general, Sauvages had accomplished for these general diseases, and his magnificent work, revised by the medical men of Montpellier, of Vienna, and of

Upsal, had excited the genius of Linnæus, Vogel, Macbride, Sagar, and many others in different parts of Europe; thus, systematic arrangements, which had before been considered impossible, increased. But they increased in number only to contradict one another; their principles were uncertain, their theories obscure, and their materials badly chosen and worse arranged. To follow such guides, or to make them agree, was alike impossible. To get out of this dilemma, Pinel at length perceived that he had no resources except in himself, and that far from seeking aid from others, it was necessary to arrange diseases into a system by his own talents, forming the arrangement on their most uniform and constant relations; hence he gained for his lectures more firmness and decision, for every one expresses his own ideas better than the ideas of others. Such was the origin of the work which spread so widely the renown of Pinel, and which in the course of the year 1798 appeared in two volumes, under the title of "*Nosographie Philosophique, ou Méthode de l'analyse Appliquée à la médicine*." Before commenting on this work, allow me a few remarks on the terms *nosology and nosography*.

The first of these terms signifies literally the *knowledge*, the second the *description* of diseases. The first marks, then, the *end*, of which the second is only the *means*.

We, in fact, only know the existence of a malady by the appearances and symptoms manifested; but the symptoms are themselves only the effect of an internal state, or of a cause which is the true source, or, as it were, the substance of the disease. Of these two elements of disease—that which is apparent, and that which is real—it is plain that the second is the more essential, and that in a nosology worthy the name the diseases must be arranged according to this ultimum of reality, and not according to the symptoms, which are only subsequent, and which will remain as long as the reality remains, and only disappear with the disease itself.

Indeed, if nature had established a constant and invariable relation between the reality and the appearance, as between cause and effect, we could always decide on the cause from the effect, and we might take one or the other indifferently for the basis of our classification; but in a vast number of cases this relation does not exist; so that to class diseases according to their symptoms, is to risk taking the shadow for the substance, the appearance for the reality; it is to substitute an accessory for the principal, and to throw the whole subject into the most dangerous confusion.

Such, then, is the deplorable condition of medicine that we can only arrive at the reality of diseases by means of their symptoms, and that these symptoms are often not very trustworthy guides; hence it is evident that, whether we consult them or neglect them, we are placed in the alternative either of being deceived, or of being entirely ignorant as to the causes; and too often all will be chance in the treatment.

To escape these difficulties, art has done as much as possible, and it is here especially that we must admire the resources of mind that Pinel has developed in his nosography. It appears that the following are the principles on which he has reasoned:—"The nature of diseases may be simple or complex; but complex diseases cannot be known unless the simple diseases of which they are composed be themselves first understood." Hence Pinel has concluded that diseases should be considered at first individually, and described in their most simple state. To show them in this state, he has sought examples from his own experience, or from that of the most worthy observers.

In the second place, simple diseases have invariable characters drawn from their symptoms, their seat, their type, and their duration. These characters have, without doubt, very different degrees of value. Those furnished by the symptoms being necessary, are also the ruling characters; alone, they suffice to form the classes, whilst associated differently with the characters drawn from the seat, the type, or the duration, or from some accidental circumstance, such as the presence of a foreign body in the economy, they assist in forming the orders, the genera, and the species, as well as their subdivisions or families, the same as by the relation of each disease with its cause, whether proper or common; and by the different combinations of the species, Pinel indicates, more than describes, both the complications and the varieties, either of degree or of sympathy, which can affect these species. From this clever method of arresting facts, has resulted the most complete, the clearest, and the most harmoniously arranged nosology which medical literature possesses.

But if Pinel has described simple diseases alone in his nosology, or has only slightly touched on their complications, does it not follow that his work is entirely composed of nosographies? Without doubt it is so. In fact, in every nosology we must either describe or sketch. Now, to sketch is more than to describe; so that the best system of this kind is reduced to a collection of sketches or of the portraits of diseases, which we unite and group, so that they recal one another in some manner by their resemblance, or by a certain family likeness. Extreme fidelity is the principal, and perhaps only, merit in these sketches, and this merit is precisely what will always recommend the pencil of Pinel, whether, as in some cases, he has taken the objects from nature, or, as in others, when he had not the examples before him, he has taken the design and the colouring from the most authentic observations—a kind of choice to which he was led by his pure and severe taste, and by a medical tact which appears to possess something of divination. To this rare merit Pinel joined yet another, that, in his long series of these sketches, you pass from the first to the second, from the second to the third, and so on to the rest, through the classes, the orders, the genera, and the species, by well arranged transitions. There is no sudden contrast, no shock, no confusion; all is gradually shaded, consequently all is clear.

These just remarks on the excellence of the whole will never be shaken either by criticism on the details (and this has not been spared), or by the most important and, in appearance, the most substantial objections which have been admitted against nosography. There is one objection on which I shall say a few words, because it was considered final by its originators, and because, being given and received as a discovery, it shows one of those discrepancies between theory and practice by which medicine has been so often harassed. It is pretended, then, that the class of fevers is superfluous, that the fevers enter into the class of phlegmasiæ, and that Pinel had mistaken their nature when he considered them separate affections. Is this idea new? Baglivi states that the first who clearly entertained it was Diocles, of Carystus, the contemporary of Antigone. It was forgotten for two thousand years, until a military physician, Henri Screta, revived it, in Germany, about a century and a half since. Quesnay, Chirac, and others, have held it. It has been now reproduced with warmth, and founded on analogy. Because fever follows a local inflammation in one, two, or three cases, its supporters assert that this occurs always; so that, in being authorised to travel from the inflammation to the fever, they believe themselves allowed to go from the fever to the inflammation—a conclusion much too absolute in both cases. *Inflammation can exist without fever, and fever may exist without inflammation.* It will not occur, it is true, without a cause, but that this cause must necessarily be inflammatory, and that instead of being diffused throughout the whole economy, and acting at once on all parts, it should be always centred in one or more circumscribed foci, disproves the very analogy for which they contend, since, when the most careful observers have applied themselves to seek in the organic tissues the cause of the most deadly fevers, they have failed, and especially at the commencement of great pestilential epidemics. This has occurred even to Morgagni himself. It is true they shelter themselves behind the imperfections of anatomical researches; but since these, as they become more delicate, become also more decisive, respect for analogy teaches us to keep that separate which we are not permitted to confound. Still more: internal and local lesions, which necropic examination discovers, are often not the cause, but the effect, of the febrile actions, as is proved by the inflammation of the skin in variola—an inflammation which, indeed, excites a second fever, but which terminates, instead of exciting, the first; as is proved by the inflammations which an attack of intermittent fever excites, but which disappear with the attack; as is proved also by the pestilential bubo which sometimes survives the patient, and continues to enlarge even after death; and hence will arise perhaps an analogy of quite another kind, though not less important, which is, that natural inflammations might be, in some cases, means of solution created by the fever; an effect and not a cause of this fever, which still depends on something mysterious, which our ignorance will never discover.

Other objections present themselves, some of which are applicable to all nosological arrangements, others more particulary to nosography—some to the names, others to the arrangement; for example, is it not unnatural to arrange variola amongst the cutaneous inflammations? Does this inflammation of the skin constitute the disease? Is it not, on the contrary, the last stage and the effect of a former and more severe disease? Are not the nervous disorders of apoplexy secondary affections? Is not the real disease of an entirely different nature? Or, rather, is it not a mixed disease? Why arrange it in the one class rather than the other? These are plausible objections. But what is to be done? Should we remove small-pox to arrange it with the contagious, and apoplexy to arrange it among the hemorrhagic diseases? What shall we gain by this transposition? This new arrangement will be based on a relationship in the disease, as the other was in a relationship in its seat. We shall then only have substituted one relationship for another. By these relationships the same disease belongs to several classes; in reality, it can only occupy one, and it is inevitable in every arrangement to show one side only of the disease, and to keep all the rest concealed. But if this misfortune exist with regard to all systems, why urge it particularly against that of Pinel? With respect to the nomenclature of diseases, it is sometimes uncertain; for example, to the term which indicates the class another word is joined to show the order, and this second word is borrowed sometimes from a local symptom, from whence are derived the names of angio-tenic and meningo-gastric fevers; sometimes from a general symptom, whence are derived adynamic or ataxic fevers. Lastly, the nomenclature is sometimes erroneous, inasmuch as it expresses a false judgment or idea. Such is the term adeno nervous fever, substituted unnecessarily for the term plague; for in the plague, as Larrey has seen it, the seat of the buboes is not in the lymphatic glands of the groin and axilla, but in the cellular tissue surrounding them. Hence we may conclude that the best mode of naming diseases would be by such terms as plague and syphilis, which indicate *states of the system*, without awakening any idea of cause or locality; the same as in chemistry, the best terms are those which refer to substances without indicating their properties.

On this point I have done; all that has been said either for or against nosologies is reducible, I think, to two propositions—the one favourable, the other unfavourable. The first is this: some order among diseases is necessary, for the mind unites or separates things according to their resemblances or differences, even against our will; the second is that every order, and every system, resting only on a few relations, if the other relations be not wholly excluded from view, they are there at least in the lower ranks, and too far distant from the consideration.

For the rest, nosography had not at its commencement that perfection of a whole, of details and of nomenclature, which it possesses at present. The editions of this work succeeded one another rapidly, it is true, but in their intervals Pinel profited by the remarks which were made to him when he found them judicious, and adopted them in the subsequent edition. The most sensible amelioration was that contained in the fifth edition, in 1813; proposed the previous year, by M. Capuron, and published in the second edition of his "Nouveaux Eléments de Médicine"—a treatise written in Latin, by a man who, professing Pinel's doctrines, was so careful of his master's fame as even to hide the defects in his original work, and supply them with corrections. By degrees, the nosography spread throughout Europe; and whilst it was being translated every where, the first impression it had produced in France was daily becoming more profound. It was above all great in the Parisian

School. The pupils, charmed by its clearness and simplicity, which led them to the most important practical truths, no longer took any other guide for their studies. A crowd of distinguished pupils, full of admiration for the work, and respect for the author, requested him to give clinical lectures. Pinel yielded to their importunities; he gave clinical instruction. Each disease was studied, analysed, and characterised by him before their eyes. These observations were collected, and, after a few years, produced a new work, which appeared in 1802, entitled "Medicine Clinique"—a work in which the diseases seemed to arrange themselves in the order prescribed by the nosography. This clinical instruction was nosography put in action to the letter. It proved that Pinel could perform his own precepts, and this exact conformity between precept and performance was the best recommendation of both. What sound views on the progress of acute and intermittent fevers, and on their too rapid suppression! What a just appreciation of bleeding, even in the greatest internal inflammation! In those inflamations of which art, no doubt, must moderate the violence, but which are subjected to laws that must not be interfered with. Pinel was after some time enlightened on this point by experience. In 1791, he had seen acute diseases of the chest much embarrassed in their course after bleeding, passing with difficulty, and after frequent lapses, to a doubtful convalescence; whilst, when treated without this dangerous aid, the same diseases progressed rapidly, and without trouble, to a cure. Was he then exclusive in his treatment? Certainly not. In this, as in all things, he taught a happy medium. Wonderful circumstance! Pinel, in 1792, suddenly compelled to manage the Bicêtre, by his own avowal, hesitated, and was uncertain what to do among this crowd of patients. In 1800 he had become master, and supreme master.

(To be concluded in our next.)

HOSPITAL REPORTS.

UNIVERSITY COLLEGE HOSPITAL.

Reported for the Medical Times by H. J. M'Dougall, M. R. C. S. E., late House Surgeon.

Fungoid Disease of the Head of the Right Tibia.—Amputation.—Recovery.

Harriet Pink, ætat. 29, a servant, of moderate conformation, and somewhat anemic appearance, was admitted, under Mr. Quain, on the 26th November, 1844. She states that her family are all healthy, and she has always enjoyed good health, with the exception of occasional fainting fits, until about twelve months since, when she first accidentally observed a trifling enlargement of the outer part of the knee, which she attributed to her "having pressed it against the side of the bed whilst nursing her mistress." She suffered no pain or uneasiness in this swelling, and paid no attention to it. About ten weeks since she fell down stairs, and struck the enlarged part, after which it increased in size considerably, and caused her great pain. Blood was extravasated from the knee to the ankle in consequence of this fall.

She then first sought medical advice, and a tight bandage was applied, which caused her very severe pain, so great that she was obliged to remove it, and foment the limb. She has had no catamenial discharge for three months, but was quite regular previously. On admission there was a considerable enlargement, with an obscure feeling of fluctuation over the outer tuberosity of the head of the tibia. The integuments covering this swelling were not much darkened in colour, nor were the veins very apparent. Her appetite was pretty good, and she slept during the first part of the night without an opiate.

Nov. 30. Mr. Quain punctured the swelling with a narrow bistoury, but no fluid escaped, although there was the same feeling of fluctuation present as at first. There was a profuse discharge of blood from the puncture. A probe was introduced into the wound, which passed for fully three inches in a direction backwards and across the limb, so as to make it evident that it must have penetrated far into the cancellous structure of the head of the tibia. No diseased bone could be felt, and the puncture was then closed by isinglass plaster. During the night she had severe rigors, a slight blush of redness appeared round the puncture, and the swelling increased considerably. This redness increased, the integuments became tense and shining, and there was considerable fever present for two or three days, which yielded to fomentations and saline remedies, and on the 4th of December the swelling was covered with tepid lead lotion. On the 5th, there was a discharge of a greenish fluid, containing flakes (like inspissated bile) from the puncture. The integuments had assumed a dusky red hue, and large veins became apparent. On the 10th, a gelatinous-looking fungus appeared at the opening originally caused by the puncture, which had been very considerably enlarged by ulcerative absorption. This fungus was covered with a yellow flaky crust, similar to the flakes which had been previously discharged. The integuments presented a more dusky appearance, and the veins were very apparent. The patient's health had not as yet suffered at all, nor could any enlarged glands be detected in the groin. On the 20th, the fungus had increased considerably, and appeared through another opening caused by ulceration. It had bled once only during the night (on the 19th), but not more than four ounces of blood were lost. The patient's health had not suffered much, but, in consequence of the pain in the tumour, she was obliged to take large quantities of opium at night. No glands were enlarged. The tumour increased more rapidly from this date, and on the 24th she consented to amputation, which was performed immediately in the lower third of the thigh by two lateral flaps. Numerous vessels required ligature. All oozing had ceased about four hours after the operation, and the flaps were approximated by three sutures and isinglass plaster.

25th. The patient passed a good night, having had recourse to laudanum. The stump looked well, and a few cuts were made in the plaster to allow the discharge of the superabundant secretion.

On the 27th the sutures were removed, but the isinglass plaster allowed to remain. There was a little discharge escaping by the side of the ligatures. She had a chop to-day, and ate with appetite. From this period the stump progressed favourably; the ligatures came away at the usual time, and the small suppurating surface caused by their presence healed rapidly. The patient's health improved much, and in three weeks from the date of the operation, she was able to get about the ward on crutches. There was no enlargement of the inguinal glands. Her catamenia had not returned, when, on the 5th of February, she went into the country. On the 27th of February she wrote to the nurse of her ward, stating that she had improved considerably in health, and that she had then, for the first time, a return of the catamenial function.

Examination of the Limb.—A vertical section was made through the lower end of the femur, the knee-joint, and the head of the tibia. The joint was found unaffected by any disease, but the cancellous structure of the head of the tibia was entirely destroyed by a medullary mass, which was continuous with the fungus that appeared externally. Nothing but the shell of the bone remained in any situation, and this had given way in front, and to the outer side. The soft parts were healthy, except where they covered the disease.

Fungoid Disease of the Orbit.

Henry Surridge, ætat. 4 years, a remarkably fair child of strumous habit, was admitted under Mr. Quain on the 25th of February, on account of a small tumour occupying the upper and inner part of the right orbit. His mother stated, that he had always enjoyed good health, with the exception of an attack of croup when twelvemonths old, until a few weeks since. He then first complained of languor and disinclination to follow his usual amusements, and about five weeks ago the upper lid of the right eye was observed to droop, and a small, soft, and not at all discoloured, swelling appeared, seemingly in the lid, in the situation of the present tumour. Several medical men were consulted, and as he did not improve he was brought to the hospital. His father is a healthy man, but his mother has an anæmic appearance. She has had five children besides the present patient, all of whom have died of strumous diseases before puberty. None of her family have been affected by cancer or any malignant disease, as far as she can remember.

Present State.—The globe of the right eye is pushed downwards and outwards, carrying before it the outer commissure of the eyelids, and a tumour, the size of a hazel nut, hard, but elastic, projects very slightly under the roof of the orbit towards the inner canthus. The integuments of the lid covering the tumour are of a dull purplish hue, and marked by large veins. The eye itself has a natural appearance, but he complains of pain in it and over the orbit, and vision is lost on that side. There is no loss of the intellectual faculties, nor any other symptom of affection of the sensorium. Tepid lead lotion to be applied to the swelling, and attention to be paid to his general health.

Feb. 28.—The swelling increases in size rapidly. A consultation was held on the case to-day, when it was decided, that any interference with the tumour would be improper in its present doubtful state.

March 6.—The tumour has increased rapidly since last report. The integuments are deeper in colour, and the veins very apparent. The patient is peevish and restless, he complains constantly of weariness; his appetite is very capricious. Ordered a few drops of tincture of henbane in a draught, with citrate of potass three times a day.

9.—The tumour burst to-day through the conjunctiva, and about a drachm of sanious fluid was discharged. The child becomes more irritable and peevish, and complains of great and constant weariness, even if not moved from his bed. There are no cerebral symptoms.

10.—A gelatinous looking fungous mass, the size of a pea, protrudes from underneath the upper eyelid. The eye projects more.

15.—The fungus has a reddish appearance; appetite very capricious, but at times ravenous The little patient constantly complains of being "so tired." There are no indications of affection of the cerebrum.

18.—Hemorrhage occurred to-day from the fungus to the extent of three ounces. It was suppressed by the application of cold, leaving him much exhausted. He has incontinence of urine.

20.—Notwithstanding constant care and attention, a small slough has appeared on the right hip. Urine still constantly dribbles from him. Feet slightly œdematous.

21.—The contents of the eyeball escaped to-day.

28.—The tumour still increases, and the patient becomes daily weaker. His appetite is ravenous, and he desires the most extraordinary articles of food.

April 5.—Bleeding has occurred two or three times since last report. The tumour increases, and the globe of the left eye protrudes a little between the lids, with a viscid discharge from the conjunctiva.

10.—To-day the remains of the membranes of the right eye sloughed off. In spite of all care the slough on his right hip increases, and there is a little redness on the left. There are no symptoms of affection of the brain. His feet, legs, and scrotum are very œdematous.

16. No urine has passed since yesterday. A catheter was introduced after some little difficulty on account of œdema of the prepuce, and nearly a quart of dark coloured very fetid ammoniacal urine withdrawn. The tumour is less in the right eye; the appearance of the left is much the same. From this period till death, the catheter was daily introduced night and morning, at which times at least a pint of most offensive ammoniacal urine was evacuated. The patient remained almost motionless on his back, moaning faintly at times when disturbed, until the afternoon of the 24th, when he died.

Examination twenty hours after death.—Externally the body was very much emaciated. There was a large slough on each hip, so deep as to bare the trochanter on the right side. The tumour of the right eye had become much less during the last few days, and much paler in colour. There was no external appearance of disease in the left eye. On opening the skull the dura mater was found very firmly adherent. The brain was pale and bloodless, but otherwise healthy. On its removal the upper wall of the right orbit was found in a partial state of

caries, although the disease in the orbit had not penetrated. On removing the roof, the whole contents of the right orbit consisted of a greenish yellow substance resembling concrete pus. The terminal ends of the optic and third nerves were similarly affected: there was a good deal of the same deposit in the left orbit. The floors of both were discoloured and perforated by the disease, which extended into each antrum of Highmore. The diseased structure also extended through the ethmoid bone between the orbits, and involved the lachrymal gland of the right side. The lungs were healthy, but very pale; the pericardium and heart healthy. The abdominal viscera, with the exception of the mesenteric glands which were enlarged, and the right kidney which had spots of the greenish matter in its structure, were healthy. In the pelvis the bladder was found much distended with fetid urine. The mucous membrane was studded with ecchymosed spots, and a small tumour the size of a nut, of the green substance, was found at its fundus. The trigone vesicale was discoloured. On the whole of the anterior surface of the sacrum a layer of the green substance was found, an eighth of an inch in thickness.

NOTICES TO CORRESPONDENTS.

A Handsome Portfolio *for holding the* "Medical Times"—*very desirable to those who would keep the numbers clean for binding, and easy of reference—may be had, by order of any Bookseller, or at the Office, price 5s. An allowance is made to the trade.*

☞ ☞.—*Several subscribers, in arrears, are requested to forward immediately the amount of their accounts, in order that their names may not be placed in our list of defaulters.*

L. M.—*Dr. Knox's interesting lectures will be resumed in the commencement of October.*

An Annual Subscriber *suggests that the Sydenham Society should publish works of a more practical nature. Another Correspondent has written to us recommending the Society to advertise their works when ready for delivery. We have not forgotten this subject, and intend to refer to it in a short time.*

A Constant Reader.—*The University of St. Andrew's requires the candidate to produce certificates of moral character, and to subscribe to a declaration that he is twenty-one years of age. If not in possession of the degree of M.A., he must undergo an examination as to his proficiency in the Latin language. He must produce certificates that he has regularly attended lectures delivered by professors in some university, or by resident fellows of the Royal Colleges of Physicians or Surgeons of London, Edinburgh, Glasgow, Aberdeen, or Dublin, for at least four complete winter sessions,* or three winter and three summer sessions, *on the following branches:*—1, *anatomy, two courses of six months each;* 2, *practical anatomy, twelve months;* 3, *theory of medicine, or physiology, one course of six months;* 4, *chemistry, one course of six months;* 5, *practical chemistry, one course of three months;* 6, *materia medica and pharmacy, one course of six months;* 7, *surgery, one course of six months;* 8, *clinical medicine, one course of six months;* 9, *practice of medicine, one course of six months;* 10, *clinical surgery, one course of six months;* 11, *midwifery, and diseases of women and children, one course of three months;* 12, *an apprenticeship, or six months' attendance in the shop of an apothecary, or in the laboratory of a public hospital or dispensary;* 13, *attendance at a public hospital, containing not less than eighty beds, for at least eighteen months. These regulations are invariably observed,* except *when the candidate is possessed of a surgeon's diploma or license from the colleges of London, Edinburgh, or Dublin, or the faculty of physicians and surgeons of Glasgow, or a license from the Apothecaries' Company, in which case he has merely to present such diploma or license, previous to examination for M.D. The graduation fee is 25l. 3s., and the examination takes place on the first Tuesdays in May and August.*

J. W. H.—*An article on the subject of our correspondent's inquiry appeared in a recent number of* Chambers' Edinburgh Journal, *to which we must refer him for information.*

Dr. Watson's *very valuable paper on* "the Toxicological Effects of Guano," *shall appear in our next.*

Mr. Coles' *work on* "Spinal Affections, and the Prone System of Treating them," *has been received, and shall be noticed shortly.*

We regret that from press of matter we are compelled to postpone the papers of Dr. Lewins *and* Philo O. P. Q., *till next week.*

An Infantry Sub.—*We do not answer questions of the nature addressed to us by our correspondent.*

A Reader.—*The garbled and half-suppressed portions published of the Judge's speech, just prove how strongly interested in not publishing the whole truth, must have been the peccant party who could resort to so obvious and suspicious a manœuvre. The statement that a proprietor of this journal canvassed for subscriptions, is not only a falsity, but a* forged *falsity. But the whole affair is but one proof more of the depraved unprincipledness and painful social necessities of the person obliged to have recourse to trickeries so very transparent. It was the misdirection of the Chief Baron's address, that induced Judge Platt to grant leave to move the court for a new trial.*

H. B.—*Dr. Weatherhead's subscription to the Medical Times Testimonial was 3l. 3s. His letter on the subject of the trial is in a previous paper.*

Mr. Reedal's *resolution is an advertisement—but a libellous one. It retracts the Sheffield resolution on the Provincial Medical Journal.*

THE MEDICAL TIMES.

Saturday, September 6th, 1845.

Fas est et hab hoste doceri.

Judging from an article in the organ of the Pharmaceutical Society for September, the Chemists and Druggists are to give the proposed Bill of Sir James Graham a stout opposition during the next Session of Parliament. As a counterpoise, however, to this bellicose announcement, we are favoured with the assurance, that if the polite and honourable, and remarkably consistent gentleman, called Mr. Thomas Wakley, persist in annoying Parliament and the Profession with his scheme of Medical Reform—whatever it may be—the Chemists and Druggists are to give him their best support. The facts seem strange; but let us hear the organ of the Pharmaceutical Society speaking for itself and friends, and against Medicine and the Medical Profession. Thus denounces Mr. Jacob Bell the Bill of the Government:—

"The bill in its present form is in some respects more objectionable than any of its predecessors, and it will be the duty of our body respectfully to solicit the introduction of several very material alterations, and in the event of this being refused, to offer to the bill the most determined and vigorous opposition."

Thus praises Mr. Jacob Bell the scheme of the medical representative, enjoying the honour of being universally disclaimed by the Profession:—

"It is one of the best schemes that has been proposed for the consideration of Parliament."

* * * * * *

"It will, therefore, be absolutely necessary carefully to watch the progress of the bill, *in the event of its introduction!*" (*exactly!* in the *event* of its introduction!) "before Parliament, although the programme appears to be QUITE FAVOURABLE, and entitled to OUR support!"

Such are the opinions of Mr. Jacob Bell and the numerous body of which he is the *scientific* representative! Such his deliberate convictions on the two measures, the proposal of legislation by the Government on one hand, and the "programme" (how well called!)—the *programme* of his friend—we beg Mr. Bell's pardon—of his *pharmaceutical* colleague's legislative *farce* on the other! Let us dismiss, however, as below a further thought, the medico-political bubble that has no object but to hoax, cajole, and take the place of the other bubbles, that have been blown and burst in such rapid succession in the eyes of a half laughing and wholly-disgusted Profession. We proceed to say a word on the Government measure which is thus exciting so much hostility.

The first point which has the honour to win Mr. Bell's condemnation is the bill's provision in reference to the privileges of the Apothecaries. The bill not only reserves to all General Practitioners the privileges which the Apothecaries' Act of 1815 conferred on them, but does not contain the clause which exists in that statute reserving the previously acquired rights of Chemists and Druggists to practise as Chemists and Druggists. Now, if we understand the matter, the Act of 1815, with or without an exceptional clause, does not preclude the legitimate pharmaceutical practice of the Chemist and Druggist. The law has clearly determined, that to practise as an Apothecary is to act in the mingled character of a dispenser of the drug and a donor of the medical advice; and it is scarcely to be anticipated that the shrewd Pharmaceutical body will present themselves before Parliament with the request to be made "medical advisers." No exceptional clause can give them that, and short of that, they have every right they can claim protected to them, without an exceptional clause. To us, therefore, the noise about the reservation in the new bill to Chemists of the privileges they fairly possessed before 1815, is so much unmeaning clamour; and we are so little concerned about it, that we are quite prepared to suppose that the omission of the exceptional clause in the present bill is wholly accidental, and to offer no objection to its return. The Medical Profession wants to infringe on no right of any class, and certainly not of the class of Chemists and Druggists. The legitimate following of a pure pharmaceutical practice is of service, and of vast service, to the progress of medicine: the law cannot, and does not seek to confine it except in its due limits; but, if thus we seek the reservation of the rights of others, we do not, therefore, forego any of our own. We do not wish to place the Pharmaceutists in a worse position in reference to us than they now legitimately occupy; and we cannot consent that at our expense they shall be placed in a better.

Mr. Bell next rings out an alarm at the institution of the New College of General Practitioners, about which he has such extraordinary opinions, that we must fain hope that he is a more safe authority on the mysteries of Pharmacy than on the intricacies of Medical Politics. We are told, with an odd appreciation of language, that "Medicine and Surgery are *cut off,* and Midwifery is *struck out,* and nothing remains but a new Society of Apothecaries, an institution which can confer no degrees in what are *termed* the higher branches of practice, but whose powers are limited to the granting of licenses to practise Pharmacy and *attend patients!*" What a droll notion must Mr. Bell have of "*attending* patients!" It is not "Medicine and Surgery," for they are "cut off;" not Midwifery, for that is "struck out;" it is not a "higher branch of practice," for no degrees are granted in them; it is not "Pharmacy," for that is spoken of as something distinct! In good faith, then, Mr. Bell, what is it? Unhappy Medical Practitioners, that have no more "high" or honourable function to perform than "attending patients!" But we are hasty; Mr. Bell is a chartered Pharmaceutist, and as such it is one of the rights he stickles about to attend patients,

and not be burdened with any knowledge of the "cut off" and "struck out" "higher branches of practice!"

Let us just assure Mr. Bell, that though in the Act of Parliament the title of the New College will be shortened, in the Charter it will be quite as explicit as ever; that though it were not, it would not matter a single rush, while the New College secures a paramount control over the surgical, medical, and obstetrical curricula and examination of its candidates, and while the latter stand before the public with the testimony of every Medical and Surgical College of this country in favour of their professional skill and competency. The *fear* of Mr. Bell is not that the new body will degenerate into a Pharmaceutical one, but that it will enforce the penal clauses of the Act of 1815 with increased energy against disrespectable poachers on the professional manor; and the *hope* is, that by delaying or frustrating the present bill, an act may be passed for separating Pharmacy wholly from Medical Practice. The *fear* may not be unreasonable; the *hope* is absurd. There must be a change in all the habits of the English people before the disconnection has a chance of success. At the present day, the result would be not only to take Pharmaceutical practice from the Medical Practitioner, but to transfer Medical practice to the Druggist. For at least another quarter of a century, advice and drugs must be had at the same source by a large portion of our population; and if they cannot get them from the doctor, they will from the druggist.

PROGRESS OF FRENCH SCIENCE.

(FROM OUR OWN CORRESPONDENT.)

Paris, August 29 1845.

Academy of Sciences; Meeting of the 25th of August.—M. Elie de Beaumont in the chair.

M. Flourens read a paper on the formation of new bone, and laid before the Academy a series of experimental researches on the subject. Duhamel had concluded from his experiments that the increase of the medullary canal of a bone is due to the elongation of its fibres, whereas Professor Flourens conceives it to be the result of absorption. In order to demonstrate the fact, M. Flourens proceeds in the following manner: instead of using, like Duhamel, a metallic ring, which presses upon the fibres of the bone, he introduces under the periosteum a plate of platinum, two lines in length by one in breadth, and so light as not to cause a pressure of any importance. The periosteum first unites over the metal, and new layers of bone becoming interposed between it and the periosteum, the platinum plate is gradually brought nearer and nearer to the medullary canal, in the cavity of which it becomes free after a space of thirty-six days (for the tibia of a dog).

Four preparations laid on the table showed the progress of the metallic plate through the bone, or rather, to speak more accurately, in the sense of Professor Flourens' opinions, showed the gradual secretion of new bone under the periosteum, and the absorption of the inner plates of the bony structure.

Professor Arago brought forward some letters he had received, relative to the late meteoric phenomenon observed in the vicinity of Rouen.

On Tuesday, the 19th inst., the thermometer was at 0·757, and suddenly fell, towards twelve o'clock, to 0·740; at the same time a very hot draught of air was noticed, immediately preceding the storm. A rolling sound, like that of approaching hail-clouds, was distinctly heard, and the whirlwind appeared, assuming a conical shape, with its basis towards the clouds, and its summit, red and fiery, to the soil. Impelled with fearful violence, it rushed forwards, uprooting and breaking the stoutest trees, and striking chiefly three factories, where large accumulations of iron existed, and sparing houses where the same cause did not attract its fury. The bars and spikes of the engines have acquired, probably from the electric discharge, strong magnetic properties. Various objects are stated to have been carried immense distances by the hurricane; a plank, belonging to one of the destroyed factories, was found nine leagues, upwards of twenty-five miles, from the seat of the disaster. Sixty lives have been sacrificed, and more than one hundred and fifty persons are badly wounded, many of whom are not expected to survive. The bodies of some of the victims presented no lesion whatever, and decomposition set in very rapidly in all.

Crystallisation of Silex.—Important to the Manufacturers of Optical Instruments.—M. Ebelmen, who has obtained, by a solution of silicic acid in ether, a compound which he calls silicic ether, further shows that by the evaporation of that substance in a moist atmosphere a plate of silex is deposited, perfectly translucid, and quite free from *double refraction*, a circumstance which must give it a great value in the construction of telescopes and other optical instruments.

Twins united by a common Abdomen and Pelvis.—Observation communicated by Dr. Decertz.—The head, the thorax, and upper extremities of each child, are distinct and perfect in every respect; a common abdomen unites the two bodies; a single umbilicus, one anus, one urinary meatus exists for both children; the two hearts are isochronous in their pulsations. One of the children only has hitherto consented to take the breast; and it is a singular fact, that it is the other, who is fed only by the projection of a few drops of milk in her mouth, who thrives and utters cries. They were contained in one ovum; a single placenta existing for both, to which they were attached by only one cord

Academy of Medicine; Meeting of August 26th.—M. Caventou in the chair.

The minutes of the last meeting being read, and unanimously adopted, M. Longet read an interesting paper on experimental physiology, entitled, "Causes of Disordered Station and Locomotion, consequent upon Division of the Posterior Cervical Muscles." The following is an extract of the memoir:

Physiologists have noticed remarkable disorder in the co-ordination of the movements of station and progression in animals, after the evacuation of the fluid contained in the arachnoid membrane. This disorder they have attributed to the removal of the pressure of the fluid on the brain and spinal corn, and they have looked upon its speedy reproduction as the chief cause of the restoration of the regularity of muscular contraction. M. Longet's interesting researches have led him to a different conclusion: he is of opinion the disturbance, and the impossibility of anything like regular progression in the operated animals, are not the results of the evacuation of the cerebro-spinal fluid, but are due to the mere division of the muscles of the cervical region. Dr. L. has often allowed the cerebro-spinal fluid to escape, without noticing any disorder in the nervous system; but when the spinal muscles of the nape of the neck are divided, in a dog for instance, the head immediately droops, the physiognomy loses its intelligent expression, the equilibrium is destroyed, and the animal falls to the ground; he soon recovers, however, and makes an ineffectual effort to rise and walk, but staggers as if intoxicated.

Rabbits, cats, and horses have exhibited the same symptoms, when, after the division of the suboccipital muscles, the drooping head was supported by the hand of the operator so as to restore it to its natural attitude, the effects alluded to instantly disappeared.

In the horse, the axis of the head and that of the neck, form almost a right angle; it is rather more open in the sheep, and more obtuse still in the dog. Now the functional disorder consequent upon the operation is greater in dogs than in sheep, in sheep than in horses, thus remaining in direct ratio with the sinus of the angle of union of the head and neck.

The simple division of the muscles of the posterior and superior cervical region having sometimes occasioned death in rabbits and in dogs, M. Longet has had an opportunity of observing the alterations produced; he has found considerable congestion of the cerebrum from pressure of the basilar artery against the base of the cranium, and believes the bulb to have undergone compression from the changed position of the head.

Results analogous to those above described have not been produced by forcing the heads of animals into a flexed position, and maintaining them with the assistance of bandages. Why? Is it not, that after the section of those muscular structures which support the cranium in its natural place, the occipital bone becomes bent upon the atlas; whereas, the head being merely bound down, the flexion is a combined movement divided amongst all the cervical vertebræ?

M. Longet concludes: 1 That the cerebro-spinal fluid is without influence over the organs of voluntary motion; 2 It is to the section of the muscles of the poster. super. cervical region we must refer those disorders of locomotion usually attributed to the escape of the arachnoidean fluid; 3. The same results are not observable in birds, on account, *a*, of the lightness of the bones of the cranium; and *b*, of the position of the occipital foramen; both of which circumstances permit the head to retain its position after the section of the muscles; 4. In the mammiferous animals the alterations of motion are in proportion with the sinus of the angle formed by the head and neck; 5. The phenomena observed closely resemble those of a lesion of the cerebellum; 6. It is the restoration of the natural attitude of the head, not the speedy reproduction of the arachnoidean secretion, which causes a cessation of the accidents; 7. The mere section of the soft parts of the nape may occasion death by producing congestion of the cerebrum.

Arsenic in Ague.—M. Boudin, physician to the military hospital at Versailles, reports to the Academy the result of his practice in intermittent affections. He has exhibited arsenical preparations to 2,947 patients in the space of five years with the most beneficial results. The preparation he employs is a solution of one grain of arsenious acid in a pound of distilled water; three ounces constituting the common dose.

Hernia Cerebri.—Professor Velpeau mentioned a case of hernia cerebri observed in a child who lived fifty-one days. The hernia issuing from the skull through an aperture, eight lines in diameter, formed by a congenital division of the bone, immediately beneath the occipital protuberance, was punctured twice during life, and the second time about one pound of transparent serum escaped from the cavity. The tumour contained almost the entire brain, but in a softened condition, and presenting many points of suppuration.

Colica Pictonum—Treatment by the Sulphuret of Iron.—M. Sandras, physician of the hospitals, recommends the following treatment:—After bathing the patient, and exhibiting a brisk purgative, M. Sandras employs the sulphuret of iron, which is administered several days after all accidents have apparently ceased. M. Sandras has found this plan successful in fifty-four cases, including all the varieties of saturnine intoxication. He conceives the preparation of iron must also tend to cause a complete cure, by removing, independently of its antidotal action, the chlorotic state observable in most of the patients who suffer from the action of preparations of lead.

Abnormal Anus—Cure by a Plastic Operation.—B, ætat. 45, was operated on the 2nd of December, 1842, for strangulated hernia. Gangrene having set in, an artificial anus was formed in the left inguinal region; it had existed for two years, and resisted several attempts at obliteration, when the patient entered the hospital St. Louis. M. Jobert succeeded in curing this disgusting deformity by the following plastic operation:—An excision was made of the healthy textures on each side of the artificial anus, and the soft parts were pressed forward and united over it by six twisted sutures for six weeks or two months; a very small quantity of fecal matter continued to escape from the upper and lower angles of the cicatrix, but they have gradually become completely obliterated, and the patient is now completely cured.

M. Jobert presented him to the Academy for examination.

DAN. M'CARTHY, D.M.P.
President of the Parisian Medical Society, late Interne of the Hospitals of Paris.

PROGRESS OF GERMAN MEDICAL SCIENCE.

By Sigismund Sutro, M.D.

On the Formation of Solid Bodies in Synovial Cavities.—According to the general idea, these bodies are found outside the synovial membrane, and enter the articular cavity by pushing the membrane before them; therefore, they adhere at first by a little neck formed of the membrane, which at last breaks, and they fall into the cavity. The author observed the following case, which contradicts the above view. From a tumour of the knee, which broke after some time, a granular mass was discharged, all the granules of which were of equal size and quality, regularly oval and flat, one and a half lines long, three-fourths of a line broad, and half a line thick. No pedicle could be perceived adhering to any part of them; they were all of a yellowish-white colour, shining, and united into masses by means of a smooth, transparent, fluid menstruum. They were very elastic, and could be easily compressed. The mass was uniformly granular, and displayed no sign of organisation. These corpuscles did not consist of fat, for they were not changed in any way when treated with ether; acetic acid caused every corpuscle to swell to three times its size after a few hours, and to become semi-transparent. If several were exposed together to acetic acid, they combined to form a mass very similar in appearance to the corpus vitreum. They were not changed by water; alcohol caused them to shrink considerably. But even after subjecting them to these agents, no organisation could be discovered under the microscope. From the above it seems likely that these corpuscles are transmuted epithelial cells. The internal surface of the articular synovial sacs is covered with an epithelium; and though this cannot be thrown off from time to time, as on the external surface of the body, still some change of matter must take place in it. It is not improbable that, from an unusual determination of blood and increased exudation, the epithelium may be thrown off the synovial membranes. By remaining for some time in the synovia, these separated epithelial cells are changed, perhaps through endosmosis of the synovia (for the corpuscles in question consisted almost exclusively of albumen), and surrounded by precipitated synovial fluid. When such corpuscles are found in synovial membranes, which possess no epithelium, of course their formation must be explained otherwise; but still there may be, in such a case, a communication of the non-epithelial cavity with an articular capsule (for instance, the bursa subscapularis with the capsule of the shoulder-joint, the bursa iliaca with the hip joint, &c.) Dupuytren's view is not to be entirely rejected, viz., that these corpuscles are hydatids, particularly when hollow in the interior, and furnished with a divided cover.—*Dr. Bidder in Henle's u. Pfeufer's Zeitschrift.*

Insanity caused by Water and Hydatids in the Brain.—A healthy woman, ætat. 54, mother of ten children, felt much excited in February, 1841, after a simple catarrhal fever, and imagined she saw ghosts; she was, consequently, treated from six to seven days in the hospital, and then dismissed perfectly healthy. In March, 1842, the excitement returned, with mania and great sexual desire She was received into a lunatic asylum, and became outrageous, and, for twenty days, only took a little fluid, and had no stools. After three months she became calmer, but, at the same time, much weaker; some appetite returned, and a swelling of the foot appeared. Afterwards she became generally weaker, and, at last, on the 3rd of August, death ensued from exhaustion. The post-mortem examination (performed thirty-six hours after death) showed general œdema, bran-like scales on the skin, great emaciation, and a relaxed state of the muscular fibre. The skull was well-formed, but the dura mater loose, with water between it and the arachnoid membrane. The brain was covered with a gelatinous mass; its substance was firm and compact, but full of small hydatids. At different places of the brain, from sixteen to eighteen cells, containing water and small tumours, were found (from the size of a pea to that of a bean). At the base of the skull, near the foramen magnum, two ounces of water were found. The pineal gland was large, hard, and not globular.—*Dr. Rüttel in Bayr Correspondenzblatt.*

Pulmonary Gangrene in Lunatic and Epileptic Patients.—An idiot, of nineteen years of age, who had long suffered from epilepsy, was sometimes affected with general trembling, which ended in convulsions, particularly after mental excitement. On a sudden, feverish symptoms appeared, with a loose cough, unaccompanied by pain. Appetite regular, bowels loose. Cupping-glasses were applied to the chest, and infus. ipecac., with nitrate of potash and tinc. digit. were administered internally. A blister was afterwards applied to the chest, when the pulsations of the heart seemed to be accelerated, though with diminished impulse. The breath possessed a fetid, gangrenous smell and death ensued in a few hours. The post-mortem examination showed the brain to be natural; the heart enlarged, surrounded with fat; and from three to five ounces of water in the pericardium. The left lung was perfectly normal, but the right was adherent to the ribs, and had a cavity in its centre the size of the fist, filled with gangrenous fluid; its walls were indurated and uneven, the stench insupportable. The abdominal organs were natural, only the convex surface of the liver was adherent to the diaphragm. Cruveilhier mentions the frequency of pulmonary gangrene in lunatic and epileptic patients. Guislain saw fifteen such cases in the lunatic asylum of Ghent.—*Dr. Wallis in Preuss Vereinszeit.*

Bronchitis during great Mental Anxiety.—In April, 1841, a peasant, ætat. 21, slender and fair, was received into the hospital of Grünberg, in consequence of excessive mental anguish. He was in full possession of his memory, judgment, power of reasoning, &c, but he could not master this internal anxiety, which made him always imagine himself attacked and persecuted. He trembled, looked downwards, wept from anxiety, and no persuasion, no argument could induce a calmer state. Sometimes he resolved to overcome the feeling by hard labour, but he always sunk back into his former anxious state. No remorse could have caused this state, since he had led an irreproachably active life till then. A girl, to whom he was attached, had rejected him, and accepted the proposal of a rival, and since that period he had suffered from the above complaint. His pulse was small and soft; pulsation of the heart weak, though regular; skin cool; appetite diminished; and sleep restless. Complexion, which was blooming at first, became pale and livid. The author ordered light animal diet, exercise in the open air, light employment, lukewarm baths, and cold douches to the chest; and, internally, valerian, with Haller's acid, assafœtida, &c. After six weeks' ineffectual treatment, the patient began to cough, felt a weight on the chest; ronchus sibilans, and foamy bloody expectoration appeared, with a feverish state, so that bronchitis could be distinctly diagnosed. As the inflammatory state of the bronchial membrane increased, his former apathy disappeared; when, by means of gentle antiphlogistic treatment, recovery commenced after a fortnight, the patient longed for occupation, and felt the perfect return of his former mental and bodily vigour According to the author's advice, occupation was procured for him at some place distant from his home, and no relapse occurred.—*Dr. Groebenschutz of Grunberg, ibidem.*

On the Qualitative and Quantitative Analyses of Albuminous Fluids.—In the methods hitherto adopted, the adhesion of the fluid to the filter has prevented a free filtration; but a very speedy separation of the albumen from the liquid is of great importance in such analyses. The albuminous liquids, when heated, either separate spontaneously into a liquid and a coagulum of albumen (a small quantity of albumen is then present), or they coagulate entirely, and form a pultaceous, gelatinous mass (in which case a large quantity of albumen is present). Albuminous urine, hydropic liquids, &c., belong to the first class; and the author proceeds in the following manner:

Qualitative Analysis.—Suppose the urine in Bright's disease is to be analysed: distinct separation of the albumen is the first object; the specific gravity is first determined by the urinometer; if the urine be of an alkaline reaction, it is then neutralised by acetic acid; from five to eight ounces are boiled in a retort and filtered through a piece of coarse linen, the urine runs through rapidly and in a clear state. The specific gravity of urine in the above disease often perfectly agrees with that of normal urine, and sometimes even exceeds it; this is only influenced by the quantity of albumen; without the latter the specific gravity is below the standard.

Quantitative Analysis.—A small quantity of the liquid (ten to twenty grains) is weighed and evaporated to dryness. The weight of the dried residue shows the quantity of solid substances in a thousand parts. Another quantity of the fluid is now quickly heated in a retort, with a small neck to the boiling point; then the retort is closed, cooled, and the contents freed from albumen by filtration. A small quantity of the filtered liquid is treated like the first portion, and the weight of the solid substances shows the quantity of albumen. If the masses to be analysed are very small, the watery vapour which escapes during the heat ought to be considered, and therefore the retort ought to be weighed before and after heating. As regards the liquids which become perfectly gelatinous by heating (such as serum of blood, &c., but very rarely urine), a considerable quantity is generally taken for the qualitative analysis, and heated to coagulation. The coagulum is divided into pieces by a piece of glass within the vessel, and is then boiled with weakly acidulated distilled water, as long as this takes up any matters. Then boil with weak spirit (water and alcohol of 0·830°) the same length of time, then with alcohol, and lastly with ether; the residue is albumen. In quantitative analysis the same care is to be observed; a weighed quantity of liquid must be used, and a second portion for the determination of the quantity of water, and of the solid constituents, of which the quantity of albumen is to be deducted to learn the quantity of the other substances. The quantity of the salts, unchanged by fire, is only found by evaporating and burning the washed residue. But if the residue of the liquid be burned with the albumen, some salts are obtained which belong to the albumen.—*Dr. Heller in Heller's Archives.*

Strange Effects of certain Remedies.—Emetics in inflammation of the lungs and other respiratory organs.

Case 1.—In a girl, ætat. 21 years, the upper part of the right lung was densely hepatised after a pneumonia of four days' duration; the left lung was posteriorly and superiorly in a state of commencing inflammation; the patient felt great pressure and lancinating pains in the chest; very teasing cough, with tough, bloody expectoration; tongue dry; typhoid expression of the face, and occasional delirium; pulse 98. A venesection of twelve ounces was performed, and tartar emetic administered according to Peschier's plan. The next day the hepatisation was found unaltered, but on the left side the inflammation had extended farther, and hepatisation was commencing; pulse 112. Venesection was again performed, and Peschier's method of treatment continued. Nevertheless, the hepatisation increased on the left side. After a restless night with delirium, the patient was found with a sunken expression of countenance, yellowish complexion, excessive dyspnœa, forty respirations and one hundred and twenty pulsations in the minute, and a strong cough without expectoration. An infusion of ipecacuanha (ʒ iss ad aq. ℥ iv) was administered. After taking a few table-spoonfuls, vomiting occurred with relief. She slept quietly for several hours, the next morning was quite conscious, and was perfectly cured on the seventeenth day.

Case 2.—A man, ætat 64, had suffered with pneumonia for five days; hepatisation occupied the whole right lung; in spite of two venesections the patient complained of excessive dyspnœa, violent cough with tough sputum streaked with blood, violent lancinating pains, extreme weakness, pulse 124. Peschier's method was employed, but the patient became lower; the dyspnœa increased, the abdomen was distended, and diarrhœa appeared; the pulse rose to 148; occasional delirium, with very difficult expectoration. To excite reaction, and to liberate the bronchi from the obstructing mucus, an infus. of ipecac. (half a drachm to four ounces) was administered for every half hour. No sickness ensued, and a drachm of ipecacuanha was

made into an infusion of four ounces, which produced vomiting, and, as in the former case, improvement and perfect recovery. Without the emetic both patients would undoubtedly have died from suffocation, caused by the bronchial obstruction.

Case 3.—A woman, ætat. 44 affected with pulmonary tubercles, also suffered from an extensive bronchial catarrh and emphysema, particularly of the left lung. The symptoms increased so rapidly, that the patient was found one morning covered with a cold, clammy sweat, insensible, cyanosis of the face, severe dyspnœa, scarcely perceptible thready pulse. Infusion of ipecacuanha was ordered, large doses of which produced vomiting and considerable relief; the emetic was repeated four times with great advantage. Later, ipecacuanha was administered with phellandr. aquat., then phellandr. aquat. by itself, and lastly Iceland moss. After a few weeks the patient was dismissed in a good state of health. In the following respiratory diseases the emetic caused great relief, though it did not save life, as in the above cases:—in bronchial catarrh; in pulmonary emphysema, particularly when caused or increased by a bronchial catarrh; in acute pulmonary œdema; and in pleuritic effusion, where an emetic is more indicated than paracentesis.

Stimulating Method in Pneumonia.—A man, ætat. 53, suffered from severe pneumonia, which extended within a few days to the whole right lung, notwithstanding four venesections. Dyspnœa, with difficult expectoration of tough, bloody sputa; delirium, unconsciousness, and convulsions of the left half of the body, and of the facial muscles, with distortion of the head towards the same side; pulse greatly accelerated, small, and to be felt with difficulty. After some large doses of musk the pulse became stronger, the convulsions ceased, consciousness returned, and expectoration of a greenish mucus ensued. A decoction of quinquina was administered, and caused a perfect resolution of the hepatisation, and after a few weeks the patient was perfectly recovered.

Case 2.—A woman, ætat. 26, suffered, notwithstanding three venesections, hepatisation of the whole right lung, and fell into a similar state to the above. After a few large doses of musk, reaction and improvement took place. She recovered completely after using Iceland moss for some time.

Case 3.—A man, ætat. 57, was received into the hospital with pneumonia of the left lung, which had lasted eleven days. Four venesections had already been instituted; the left lung was completely hepatised; violent fever, excruciating pain, and dyspnœa were present. Two more venesections were practised without benefit; the dyspnœa increased, pain and irritation continued, the patient had colliquative sweats, delirium, and lost flesh; the skin became cool, and the pulse scarcely perceptible. Camphor was now ordered in an oily mixture. After a few doses the skin was warm, pulse stronger, dyspnœa diminished, and the patient fell into a sound sleep with gentle respiration; the hepatisation was thus perfectly resolved by an expectorant and afterwards tonic treatment. It is impossible to indicate the fixed stage in which the stimulant treatment must be adopted. The author chose camphor in the latter case, on account of the depressed functions of the heart and vascular system; whilst in the former cases the weakness of the nervous system seemed to indicate musk.

Cure of a Tumour of the Spleen by Extract of Quinquina.—An infant, ætat. 11 months, was affected with an enlargement of the spleen during a diarrhœa of several weeks. The patient was much emaciated. After using, for four weeks, extract. chin. frigide parat., from a scruple to half a drachm a-day, the spleen began to diminish in size, and the tumour at last disappeared entirely, and the child became blooming and strong.

Effect of Veratrine Ointment in Neuralgia.—A man, ætat. 38, who had been affected with a rheumatic ophthalmia, still suffered from a neuralgia of the left frontal nerve, and the usual remedies were employed in vain for eleven months. The pain was irregular, burning, and lancinating, and often continued for twelve hours. The author then applied veratrine ointment (two grains to a drachm of lard) to small spots of the forehead, previously excoriated by blistering. The ointment was spread on linen, and applied at first to two spots, and afterwards to eleven spots. Within ten days the obstinate pains were perfectly removed.

Case 2.—A man, ætat. 41, suffered, after a cold, from rheumatic lancinating pains, which were at last concentrated on the nerv. cutan. femor. medius et posterior. The pains were more violent and distressing at night, and occasioned, after a fortnight's duration, loss of appetite, emaciation, and great dejection. Veratrine ointment was now used, and after a few days the pains had disappeared.

Tannin with Flores Benzoini in the Spasmodic Cough of Adults.—A girl, ætat. 23, had suffered for several weeks with violent bronchial catarrh, at first accompanied by fever; when the latter disappeared the cough also diminished, but returned periodically every two or three hours in violent paroxysms, which ended in vomiting of tough mucus. These paroxysms increased in violence, notwithstanding the use of tartar emetic, narcotics, derivatives, &c. They were accompanied by cyanosis, loss of consciousness, fainting, cold perspiration, and great muscular debility. The author employed tannin with benzoic acid (as recommended in hooping-cough), and found the disorder greatly ameliorated after the first six doses, and perfectly removed in seven days.

Secale Cornutum in Paralysis of the Bladder.—A woman, ætat. 50, was attacked by dysentery, which was followed on the third day by a paralytic state of the bladder, after the patient had suppressed with great difficulty the inclination to stool. The dysentery yielded after three weeks to the use of opium and calomel, but the vesical paralysis continued, and the patient remained weak and dejected. After the ineffectual employment of some other remedies, ergot of rye was administered at first in the dose of gr. vj, then gr. x four times a day. After a few days, the patient could discharge her urine at will, at first in drops, but afterwards more freely by degrees; in the course of a few more days, the paralysis was perfectly removed. (About three drachms of the remedy were taken in the whole.)

Acetate of Lead in Intestinal Hemorrhage from Typhus Fever.—A woman, ætat. 28, was attacked by typhus fever of a benignant character until the sixteenth day. On the seventeenth day a violent bloody diarrhœa appeared suddenly (about thirty stools in twenty-four hours), with strong meteorismus, small and accelerated pulse, and delirium. Alum was administered internally, and in the form of clysters, but without effect; the first doses of acetate of lead (half a grain every two hours), caused a decrease of diarrhœa, which ceased entirely after employing from four to five grains. The convalescence then proceeded slowly and without disturbance.—*Dr. Tacksch in Prager Vurteljahrschrift.*

PROGRESS OF IRISH MEDICAL SCIENCE.

(FROM OUR OWN CORRESPONDENT.)

Dublin, Aug. 30.

JERVIS STREET HOSPITAL.

Stricture of the Urethra, Followed by Perineal Abscess; under the care of Mr. Kirby, one of the Surgeons; Mr. Frederick Farmer, Clinical Clerk.—Dennis Hogan, ætat. 30, a clerk, was admitted to Jervis-street Hospital on the 18th of January, 1845, labouring under stricture of the membranous portion of the urethra of six years' standing. Contraction of the stricture had gradually taken place during that period, and was so great on admission that the passage of the smallest sized bougie could not be effected. The patient had been subject to temporary attacks of retention of urine, one of which, having on a late occasion continued longer than usual, induced him to seek relief at the hospital. A bougie was now passed down to the stricture, by which it was firmly grasped, and the further progress of the instrument arrested; on the third day, however, the bougie was, after some resistance, passed into the bladder. The subsequent treatment consisted in the gradual dilatation of the passage, by which means the case progressed in a very favourable manner up to the 25th of February, when, for the first time, it was observed that a small quantity of purulent matter oozed from the mouth of the instrument previous to the passage of the urine through it. The patient did not complain of any soreness in the passage; but on the 27th he felt chilly and otherwise unwell, and on the next day a high degree of fever was present. On the 1st of March the febrile symptoms were much aggravated, and the patient now came under Mr. Kirby's care, who ordered him a saline mixture to be taken with lemon-juice. On the 3rd, together with the constitutional symptoms, there was considerable thickening of the urethra, and œdema of the scrotum, and twelve leeches were applied to the perinæum, followed by an emollient cataplasm; an oily draught, containing aquæ kali gtt. vj, was administered, and an anodyne draught given at bedtime; the urine twice drawn off this day. Mr. Kirby again visited him at half-past nine, p. m., and finding considerable swelling and tension still in the perineal region, made an incision for its relief.

March 4.—The febrile symptoms not much improved; abdomen tympanitic; synovial inflammation in all the joints. Ordered a warm bath, in which he passed his urine.

At the midday visit, Mr. Kirby passed a catheter to about the distance of the bulb, when some purulent matter, of a most fetid odour, escaped from the mouth of the instrument, which, after some resistance, reached the bladder. On squeezing the spongy portion of the urethra, a peculiar gurgling sound was now observed, the cause of which Messrs. Kirby and Stapleton were at first doubtful of, but, on accurate examination, determined that it proceeded from an abscess situated in this region.

The instrument which had first been introduced was cut down upon through the perineal incision formerly made, and a quantity of matter of an exceeding fetid odour, mixed with urine, made its escape. The patient expressed himself greatly relieved, and when placed in the erect position passed water freely through the opening. Ordered stimulants.

5.—Abdominal tympanitis still present; fever somewhat lessened. Is to take a third of a grain of Ext Cannab. Ind. with five of blue pill three times a-day. The stimulants to be continued.

6.—Great distension and œdema of the penis, with an erysipelatous blush; considerable tympanitis of the abdomen, with typhoid fever. Ordered an anodyne enema, containing Tinct. Fœtid. Spirit. Terebinth., &c.; the pills to be repeated; stimulants to be continued, with wine and porter, and a turpentine fomentation to the abdomen. Towards evening, the distention of the penis having increased, an incision was made along its dorsum, as far as the symphysis pubis; the parts beneath were found in a sloughing state, and a communication existing with the urethral abscess. The patient is slightly delirious, and visibly sinking. The pills to be repeated and the stimulants continued.

7.—The typhoid symptoms still advancing; pulse small, quick, and compressible; mucous râle in the throat, extremities congested and livid; abdominal tympanitis much increased. Continuentur omnia medicamenta.

8.—Pulse hardly to be felt at the wrist; the patient highly delirious; mucous râle increased; stools passing involuntarily; sinking rapidly. Died at half past three.

Sectio Cadaveris twenty hours after death.—The integuments of the penis and neighbouring parts were greatly swollen, livid, and œdematous; the prepuce infiltrated and on the point of sloughing, with an adhesion to the glands of long standing. The body of the penis was separated from its coverings, by the sloughing of its investing cellular tissue. A section of the symphysis pubis having next been made, a large abscess was exposed, which had implicated the bulb and extended along the side of the urethra, communications existing between it and the perineal incision, as well as that on the dorsum of the penis; through this abscess the urine must have been evacuated, there being one opening posterior, and another anterior to the stricture. The stricture, situated behind the bulb, was of a cartilaginous hardness, and so much contracted that a bristle could with difficulty be passed through it; the neighbouring parts were indurated and congested; the urethra, posterior to the stricture, was inflamed; the prostate gland not much affected; bladder thickened and inflamed on its internal surface, and containing about an ounce of purulent

matter mixed with urine. On examining the abdominal viscera, the large intestines were greatly distended with flatus; the mucous membrane inflamed, but the other organs healthy. Proceeding to examine the thorax, a quantity of purulent matter was found on both sides, lying between the pectoralis major and minor, which communicated with a similar fluid between the recti muscles; the matter was not contained in a cyst, but was deposited between the muscles, which were softened and partially broken up; purulent matter was also found between the sternum and subjacent muscles, communicating with that which lay external to the thorax. Old adhesions existed between the pleura pulmonalis and costalis; the lungs gorged with mucus and serum; effusion to the amount of two ounces into the pericardium; the heart healthy, containing no pus. The joints were next examined; on cutting down to the external lateral ligament of the left knee, a quantity of pus escaped, of the same character as that mentioned above; the cavity of the joint also contained pus; the cartilages were free from disease; the synovial membrane villous, with a velvety appearance; the shoulder joints contained similar purulent deposits, but were even more disorganised. No trace of inflammation was found in the veins of the different parts of the body. The brain not examined.

Case of Contusion of the Perinæum.—Thomas Carroll, ætat. 30, a carpenter, was admitted to the hospital on the 15th of July, 1845. States that three days previously, while walking across some joices laid for flooring, his foot slipped and he came astride one of them, his whole weight falling on the perinæum. A feeling of faintness came over him, from which, however, he quickly recovered; and not thinking much of the injury, he applied to an apothecary, who ordered him a wash and some leeches, and passed an instrument (as he thought) into the bladder, but drew off nothing more than a few drops of blood; a similar attempt was again made with the same result at the next visit; and Mr. Kirby being now called at 12 o'clock, on the second day of the accident, he found the case in the following condition:—Patient suffering intense agony from retention of urine, having been unable to pass any since the occurrence of the accident. The parts in the neighbourhood of the injury ecchymosed, especially the scrotum and perinæum. A large tumour lay along the line of the urethra, which fluctuated under the finger, and was extremely painful. After an ineffectual attempt to pass an instrument into the bladder, Mr. Kirby made an incision into the tumour, giving exit to a quantity of grumous blood mixed with urine, and in a short time the patient made water freely through the opening, with great relief to his sufferings. On the 15th of July, three days after the occurrence of the accident, he came to hospital, having previously passed water on several occasions through the incision, the urine being tinged, and containing some clots of blood; as he was very nervous, and the calls to pass urine very frequent, a warm-bath was ordered and an opiate.

July 16.—Had an attack of retention of urine this morni g, caused by a coagulation of blood in the incision, which being removed, the urine flowed freely. From this period the treatment consisted in a warm-bath daily, occasional opiates, and attention to the primæ viæ. The incision in the perinæum was kept open by means of poultices, which for some days removed large quantities of coagulated blood, with great relief to the tension of the parts. By these means he progressed rapidly, but though the urine flowed freely through the incision, no sort of instrument could at any time be passed into the bladder, either by the penis, or from the incision. He occasionally suffered from irritation of the bladder, which was removed by the administration of Tinct. mur. ferri with Tinct. hyosciami and tonics.

August 19.—Urine discharged by the natural passages, and only a few drops through the incision, which has for some days been gradually closing.

29.—No urine by the incision for several days; micturition much less frequent, and can be readily accomplished, but in a contracted stream, and with some tendency to erection.

He suffers occasional seminal emissions, the discharge being large, but unattended by blood or any inflammatory consequences. The passage of an instrument into the bladder has not yet been effected, and every attempt to do so is succeeded by hemorrhage.

PROGRESS OF ENGLISH, ITALIAN, AND AMERICAN MEDICAL SCIENCE.

[The following are the only articles of interest to the profession in four numbers of the *Lancet*.]

Albuminous Urine.—Dr. P. B. Ayres says that the reason of the effusion of albumen, or rather serum, in the urine, depends on the relation between albumen and urea; and (he adds), as far as he can judge from the evidence before him, a strong relation subsists between their proximate organic principles. Whenever albuminous urine exists, urea is deficient, and the deficiency is often considerable, even when but a very small amount of the secretion is passed. The saline matter is also deficient; but in all the specimens of albuminous urine seen by Dr. Ayres there was a copious brown amorphous deposit, consisting chiefly of lithate of ammonia and vesical mucus. The urea Dr. Ayres believes to be produced by the action of respiration on the albumen in the blood, and he quotes Dr. Christison's analyses of the blood in albuminuria, showing that there is a gradual diminution in the proportion of hæmatosine and albumen, and the additional statement also, that, in the latter stages of the disease, the urine ceases to be albuminous, which Dr. Ayres concludes is accounted for by the diminution of the proportion of albumen in the blood that has taken place.

Aortic and Cardiac Disease.—Dr. Turnbull narrates the case of a powerful seaman, who was admitted under his care, with evidences of insufficiency of the aortic valves, followed by permanent dilatation and hypertrophy of the left ventricle, which again was succeeded by a similar result on the right side of the heart, by dropsy and hydrothorax, the man ultimately dying of pulmonary apoplexy. Next follow the details of a case of acute rheumatic endo-pericarditis, which was treated by venesection and mercurialisation, with the effect of removing the inflammatory action, disease of the mitral and aortic valves persisting. Another case is also one of valvular disease, following an attack of acute rheumatism. The patient was dropsical; she was much relieved by the internal exhibition of elaterium, which acted freely as a hydragogue cathartic.

Microscopic and Chemical Examination of the retained Menstrual Fluid.—Dr. Letheby availed himself of the opportunity offered by the section of an imperforate hymen, in a girl seventeen years of age, to preserve the retained fluid for examination. It had a dark chocolate colour, becoming red on exposure to the air; it was perfectly inodorous, and so tenacious that it could scarcely be poured from the vessel: altogether, it had the appearance of a dark and thick treacle. Its specific gravity was 1027, a little lower than ordinary serum. When examined under the microscope, with a power of 300, it was found to be quite free from fibrin, or rather from that form of it which occurs in the coagulum of blood—but consisted of numerous corpuscles floating in a coloured fluid. These corpuscles differed very considerably in form, size, and colour. They consisted of—1. Altered blood corpuscles, appearing oval when seen edgeways. 2. Minute granules, probably from ruptured blood corpuscles. 3. Coherent blood corpuscles or exudation globules. 4. Highly refractive globules, indistinctly nucleated, (lymph globule?) 5. Oval corpuscles, mono or binucleated. 6. Epithelium scales, and mucous globules. 7. Globules and epithelium remaining after the action of acetic acid, the nuclei more distinct. And 8. Coloured exudation, mucous and lymph globules, with plaster epithelium, left after the action of water. With the view of testing the nature of these globules, they were subjected to the action of water, ether, and acetic acid. Water rapidly dissolved the blood corpuscles, while the other globules and scales were either not affected, or but slightly, even after a long interval. On moving the glasses, it was observed that the solution of the blood discs had produced a tenacious kind of jelly, which bound the other globules together. Ether also dissolved the blood discs as well as the exudation globules and minute granules: the others were unaffected. Acetic acid rapidly acted on the blood corpuscles, more slowly on the exudation globules; the others it made more distinct, bringing out their nuclei. *Chemical examination of the fluid.*—It had an alkaline reaction, and was perfectly miscible with water; when heated a little below 212° Fahrenheit, it formed a firm coagulum. With the view of ascertaining the amount of its proximate principles, it was analysed after the manner proposed by Simon. A thousand grains of the fluid were evaporated; they gave a residue of 142·6 grains; this, when incinerated in a platinum capsule, left an ash of eight grains, of which four were peroxide of iron; the rest was soluble in water, and consisted of carbonate, muriate, phosphate, and sulphate of soda and magnesia. Another thousand grains were evaporated to dryness, over a water-bath, the residue boiled with alcohol, and then diluted with ether. By this means all the fatty matters were removed, and on evaporating the ethereo-alcoholic solution, a soapy compound was obtained, which had the peculiar odour of pastry; it was mixed with a little water slightly acidulated with hydrochloric acid, then filtered, and treated with ether, by which means 5·3 grains of a yellow semi-fluid fat was procured, which, from its fluidity and capability of being saponified, it may be regarded as oleic acid mixed with a little stearic. The residue of this operation was then boiled with dilute alcohol (specific gravity ·930) and filtered while hot. The filtered solution deposited, as it cooled, 52 grains of hæmato-globulin; this was collected on a filter and washed with alcohol slightly acidulated with sulphuric acid, until all the red hæmatin was dissolved; the residual globulin weighed 49·1 grains, and the hæmatin, when precipitated by ammonia and dried, weighed three grains, ·1 of which was, in all probability, sulphate of ammonia. The alcoholic solution, from which the hæmato-globulin had been separated, yielded on evaporation 13 grains of a brown matter, composed of 6·3 grains of salts or ash, and 6·7 grains of extractive. (The previous incineration indicated 8 grains of salts, so that 1·7 grains must have been lost during the process, or else it was in combination with the fats as soap.) The albumen which remained after the extraction of the hæmato-globulin, salts, and fats, weighed 69 4 grains; so that the results of these analyses might be arranged as follow:—

Water	875·4
Solid residue . . .	142·6
	1000·0

Or thus—

Water	857·4
Albumen . . .	69·4
Globulin	49·1
Hæmatin	2·9
Salts	8·0
Fats	5·3
Extractive . . .	6·7

The quantity of mucus, blood-corpuscles, and soluble albumen was ascertained to be as follows:

Water	857·4
Solid matters insoluble in cold water, and consisting of mucus, lymph, and exudation globules with epitholium .	22·6
Solid matters soluble in cold water, and consisting of—	
Saponified fats, and blood corpuscles .	53·8
Albumen	52·7
Salts	7

It must be borne in mind that the fluid thus examined by Dr. Letheby was not healthy menstrual fluid; for it had been retained for a considerable time within the vagina, and no doubt it had there become mixed with various mucous secretions, as well as with an excess of the exudation globule, which its presence, as an irritant, must have occasioned. As to the cause of its viscidity, this must be looked for either in some physical property possessed by the globules, or else in the chemical action of the salts or free alkali on the albumen; for the latter has the property of giving albumen a gelatinous character. One thing is certain—it could not depend on the amount of solid matters which it contained, nor yet upon the presence of coagulated fibrin. Another property which the fluid possessed,

and one which has been generally noticed, was, that it had not begun to decompose, for it had no odour, and, indeed, it appeared to resist putrefaction after its removal from the body, longer than ordinary. In comparing the preceding analyses with those of normal blood, as well as of the menstrual fluid, which have been made at various times by Simon, Berzelius, Lecanu, Denis, and others, it appears that there are many points of dissimilarity; indeed, it does not bear any relation at all to healthy blood, as may be seen by the following, which is an average of two analyses made by Simon:—

Water	795·278
Solid residue	204·822
Fibrin	2·104
Fat	2·346
Albumen	76·600
Globulin	103·022
Hæmatin	6·209
Extractive and salts	12·012

From this it differs in having no fibrin, but about twice as much fat, and only half the amount of hæmato-globulin, or blood corpuscles. The only form of healthy blood with which it can be compared is that of the vena porta, which Simon has found to contain more fat, but considerably less of all the albuminous principles, than the systemic blood of the same animal; and there are some cases of disease, such as hemorrhage and malœna, with which it is also comparable. With respect to its comparison with the analyses of menstrual blood hitherto made, it offers considerable points of difference. Simon examined the menstrual fluid, and found it composed of—

Water	785·000
Solid constituents	215·000
Fat	2·580
Albumen	76·540
Hæmato-globulin	120·400
Extractive and salts	8·600

Here the solid constituents were greater than in normal blood.

Ergot of Rye.—Dr. Ross has found the ergot of rye, combined with infusion of roses, very serviceable in the treatment of purpura hemorrhagica. He gave it in the dose of five grains of the powdered ergot in an ounce of the infusion every four hours. The patient was placed on a generous diet. Under this treatment, he says, with the addition of some aperient when necessary, the case went on with great rapidity to a favourable termination, without a single untoward symptom occurring to interrupt its progress.

Preparation of Dialuric Acid.—This acid may be obtained from alloxantin, by the protracted action of sulphuretted hydrogen; it may, however, be prepared still more readily from alloxan directly, by means of sulphuret of ammonium or cyanide of potassium. In the former case (that is, by the action of sulphuret of ammonium upon alloxan), the dialuric acid is obtained in the form of an ammoniacal salt; in the latter, in that of a potass salt. The last mother liquor left in the preparation of alloxan may be very conveniently used for the preparation of dialurate of ammonia. For this purpose the mother liquor in question is neutralised, at a low temperature, with carbonate of ammonia, and an excess of sulphuret of ammonium added as speedily as possible. Very soon after, the fluid solidifies into a paste of fine, white, and brilliant needles, consisting of the not easily soluble dialurate of ammonia. Washed with water, and dried in the air, this salt assumes a reddish tint. In the latter case, if a moderately concentrated solution of alloxan be mixed with a concentrated solution of cyanide of potassium, there forms, either immediately, or after the lapse of a few minutes, a yellowish crystalline precipitate of dialurate of potass. If this potass salt be dissolved at a low temperature, in weak potass ley, and the solution saturated with acetic acid, the dialurate of potass loses its yellowish tint, and is obtained perfectly white. Upon dissolving either dialurate of ammonia, or of potass, in warm hydrochloric acid, to saturation, and allowing the solution to cool slowly, the dialuric acid is obtained in fine needles, frequently extending to several lines in length. Dried *in vacuo*, these crystalline needles maintain their form and colour, but when exposed to the air, they speedily assume a red tint. They dissolve in water with very great facility: the solution is acid, and decomposes the alkaline carbonates, with effervescence. It cannot be kept exposed to the air without undergoing alteration, dialuric acid absorbing oxygen with great rapidity. Protracted exposure to the air makes it yield the finest and most regular crystals of alloxantin: the formation of the latter, in such cases, proceeds slowly and continues as long as there remains any dialuric acid in the solution. The formula for dialuric acid, is $C^8 N^2 H^4 O^8 = C^8 N^2 H^3 O^7 + H O$; for dialurate of potash, $C^8 N^2 H^3 O^7 + K O$; for dialurate of ammonia, $C^8 N^2 H^3 O^7 + N H^4 O$.

Pericarditis.—Dr. Taylor describes the case of a pot-boy, eighteen years of age, whom he treated for acute rheumatism, with pericarditis and adhesion of the pericardium, and hypertrophy of the ventricle, with disease of the mitral and aortic valves. It was the boy's second attack of rheumatism. The inflammation was speedily cured by bleeding and mercury, the latter pushed to salivation, but the diseased condition of the heart remained unsubdued. In another case, the ninth recorded by Dr. Taylor, the disease was subacute rheumatism. There was a friction sound, resembling a bellows-murmur, audible at the base of the heart, and not in the neck, with increased extent of dulness on percussion. The patient also suffered from convulsive twitches, followed by pains in the arms. The treatment consisted of local and general bleeding, and the exhibition of colchicum, aconite, calomel, and morphia. The patient recovered. In the tenth case, the pericarditis, after having been removed, relapsed. Its cure for the second time was followed by endocarditis and bronchitis.

Ulceration of the Ileum.—Mr Newton was called to a woman who, when apparently in good health, had been kicked on the abdomen by her husband. Mr. Newton saw her an hour afterwards, and found her presenting symptoms of abdominal inflammation. The examination of the body showed evidence of inflammatory action on the peritoneum, and some indications of effusion of a portion of the intestinal contents. There was also found, on the right side, at about the junction of the middle with the posterior third, a small circular opening in the ileum, with defined edges, surrounded by recent lymph, and accompanied by considerable vascularity of the intestine. Mr. Newton considers the case one of glaring homicide, and is of opinion that the kick on the abdomen caused the inflammation, and subsequently the ulceration. In this opinion we can by no means coincide. The ulceration was certainly of longer duration than three days; still it is very probable that the injury inflicted hastened the poor woman's death.

The Influence of Employments upon Health.—Dr. Guy has compiled from the mortuary registers for 1839 certain tables, from which he draws the conclusion that, in round numbers, the average age of all who die above fifteen years of age, among the class of gentry and professional men, is fifty-nine years; among tradesmen, forty-nine; and among the labouring class, forty-eight. The first class, therefore, live, on the average, about ten years longer than the second, and eleven longer than the third class. Compared with the more favoured classes, therefore, both the tradesmen and the labouring class are under a very great disadvantage. The former are deprived of ten years of the prime of their life, and the latter of eleven, being somewhat less than a fourth of the term enjoyed by all of the favoured class who have attained the age of fifteen. It is not, then, during childhood alone, but during manhood, too, that the poorer classes are exposed to causes of disease and death from which their more favoured brethren are exempt. Another circumstance which challenges remark, is the slight difference in the average age attained by the tradesmen and labouring class. The former live less than a year longer than the latter. It is highly probable that this difference would have been lessened, or the place of the two classes even reversed, if the deaths which took place in workhouses in men whose previous occupation is not stated had been included in the tables. As the average of all persons above twenty-one, dying in workhouses, is sixty years, this supposition is highly probable, especially as the labouring class whose employments are not specified are likely greatly to exceed the tradesmen of every degree. On the other hand, it must not be forgotten, that the class of tradesmen is being continually recruited from that of the labouring poor—a circumstance which would, doubtless, tend to exaggerate the unhealthiness of the former class, and to lower their average age at death. Tables are next exhibited by Dr. Guy showing the respective liability of the same classes to pulmonary consumption. It would appear that while the per-centage proportion of deaths from all causes, under thirty and forty years of age respectively, is greater among tradesmen than among the gentry, and among the labouring class than among tradesmen, the per-centage proportion of deaths from consumption under those ages does not follow the same order. The per-centage proportion of deaths from pulmonary consumption, under thirty and forty years of age respectively, in the class of gentry, is less than the per-centage proportion of deaths from the same causes among the other two classes; but the labouring class follows next in order, presenting a lower mortality from this disease under both those ages than the class of tradesmen. In like manner, the average age at death, from all causes, follows the order in which the several classes are placed in the table, while the average age of death from consumption presents, in the case of the labouring class, a number intermediate between the class of gentry and that of tradesmen. The ratio of deaths from consumption to those from all other diseases follows the same order as the deaths from all causes; but the class of tradesmen are very little less liable to consumption than the whole body of the labouring poor. From these facts Dr. Guy draws the following conclusions:—1. That the average age of death is higher, and the per-centage proportion of deaths from all causes, under thirty and forty years of age, is lower, in the case of the gentry than in other members of the community. 2. That the average age of death from consumption is higher, and the per-centage proportion of deaths from that disease occurring under thirty and forty years of age, is lower, among the gentry than in other members of the community. 3. That the proportion which deaths from consumption bear to those from all other diseases, is lower among the gentry, than among the other members of the community. 4. That though the per-centage proportion of deaths from all causes under thirty and forty years of age, occurring among tradesmen, is lower, and the ratio of deaths from consumption to those from all other diseases also lower, than among the labouring class, the average age of death from consumption is higher, and the per-centage proportion of deaths from that disease under thirty and forty years of age, is lower, in the case of the labouring class, than in that of the tradesmen of the metropolis. The difference existing between the class of gentry and the other two classes, in respect of their liability to pulmonary consumption, is very remarkable, and much greater than might have been anticipated. Among tradesmen the liability to consumption is little less, and among the labouring class somewhat more, than twice as great as among the gentry. This great disparity in the liability to phthisis is attributed by Dr. Guy, as it has been by all right-thinking observers, to the great advantages, both physical and moral, possessed by the gentry over the ruder sons of the creation. In the investigation of these facts, there has been elicited a peculiarity well worthy of observation, namely, that while the labouring class does not attain so high an average age as the class of tradesmen, and are rather more liable to pulmonary consumption, those of the former class who died of that disease attained a somewhat more advanced age. This is explained by the fact that in-door employments induce a greater liability to phthisis than out-door occupations. This statement, which is, we believe, generally admitted to be correct, is demonstrated by Dr. Guy in a series of statistical tables, from which he draws the following conclusions:—1. Men following in-door employments are more liable to attacks of pulmonary consumption than those who work out of doors; and those who fall victims to that disease among the former class, die at an earlier age than those who belong to the latter class. 2. Among men following in-door employments, those who use least exertion are most liable to attacks of pulmonary consumption, and perish at an earlier age than those who work out of doors. These conclusions apply

to females as well as to males, for while those who lead sedentary lives present a ratio of one case of consumption to nearly fourteen of all other diseases, those who use more exertion are affected in the proportion of one to nineteen, and those who are employed out of doors of one to twenty-two. Sedentary occupations, however, which are unfavourable to youth and early manhood, are favourable to old age, the reverse being the case with those occupations which require strong exertion. An important question arises out of the consideration of these facts—are these employments necessarily injurious, or are they made so by adventitious circumstances? Do sedentary employments, provided they are carried on in airy and wholesome places, tend to induce disease and shorten life? This question, unfortunately, however, can only be answered partially, as the poorer classes who pursue sedentary employments, are almost universally so engaged in close, ill-ventilated, and unhealthy apartments. Still, however, it may be gathered that the sedentary occupation is itself injurious; a fact which Dr. Guy conceives to be demonstrated by the relative tendency to consumption of compositors and pressmen—the ratio of consumptive cases being higher, and the age at which the disease occurs, lower, in the case of the compositor, while both these classes of operatives are exposed to the same causes of ill-health, the only difference being that the pressman has more bodily exertion. Dr. Guy concludes his paper with a series of cases illustrating the injury resulting from a want of due ventilation.

Causes of Inertia of the Uterus Productive of Protracted Labour.—Dr. J. Hall Davis says, the parturient action of the womb may be suspended or inefficient—1st, from general debility of constitution, the result of different causes, the judicious treatment of which, alone, will often restore to the organ its lost power; 2nd, from a deranged state of the nervous system, attended by loss of sleep, when the due action of the organ will be restored by a refreshing sleep, obtained by an adequate opiate; 3rd, from a diversion of the nervous influence from the uterus, by fæcal accumulations in the bowels, or by retention of the urine in the bladder, when the obvious treatment will be followed by the restoration of the parturient throes; 4th, in women who have borne several children, when, no contraindication offering, the ergot becomes the proper and efficient remedy; 5th, by depressing influences over the mind, when the assurances of the attendant of a happy issue, have often brought about a restoration of the suspended action; 6th, from no ascertainable cause of inertia, when, all other points in the case favouring, the exhibition of the ergot of rye is peculiarly indicated; 7th, from over-distention of the uterus by plurality of children, large quantity of liquor amnii, morbid products in the uterus complicating the gestation, when the treatment adapted to the respective indications will be the remedy; 8th, from the influence of general and local congestion, which being treated by general or local depletion, or both, the contractions of the organ are increased or resumed.

Laryngitis.—A case of acute laryngitis is reported from the Westminster Hospital, which terminated fatally by asphyxia, from œdema of the glottis. Tracheotomy was performed by the house-surgeon, but without advantage.

Flap-Operation for Tumours.—Mr. Chippendale, in removing a tumour from the shoulder, operated in the following manner:—Raising the tumour as far as he could from the body with one hand, he passed a long narrow knife under its skin near the border, in the direction of its long diameter; having cut through the connections at its base, and the edge of the knife having arrived at the opposite border, it was turned towards the surface of the body, and the skin severed. The whole was then turned out, and the tumour dissected from the flap thus formed, with the greatest facility. The few vessels which bled had ligatures applied, which, in a quarter of an hour, were removed; the flap was laid down on the wound with two points of suture in the long side, and the edges secured with adhesive plaster. The whole was healed in a few days, leaving a scar representing three sides of a rectangular parallelogram, as thus [. The skin when thus divided so soon shrinks that it can seldom be necessary to take any portion of it away; but should a case occur where such a proceeding became necessary, a portion could be taken from the free border of the flap, so as to make it fit the exposed surface, as parts are brought to coincide in autoplastic operations. At any rate, there would be but two incisions of the skin, as in ordinary cases where a portion is removed, and where the incisions are made in the form of arcs of the circumference of a circle, in this manner (), and his plan, he says, has this advantage, that the cutting is from within towards the periphery, which is certainly attended with less pain than when effected in the opposite direction. The knife should be passed parallel to the long diameter of the tumour, if possible, because this measure secures the smallest circumference to the flap, takes less time to cut, and diminishes the chance of having to take away any portion of skin.

Neuralgia treated by Iodine.—Mr. Clarke thus describes a case which, from his own showing, is no other than scrofulous disease of the neck and face, with probable extension of the inflammation to the nerve implicated. The continued exhibition of the ioduret of potassium, with other alteratives, effected a cure.

Strangulated Inguinal Hernia.—Mr. Dalby narrates a case of strangulated inguinal hernia, occurring in a woman sixty-eight years of age, on whom he operated. He found the tumour intimately attached to the surrounding parts by remarkably firm and evidently old adhesions. It was with extreme difficulty, with the finger and handle of the scalpel, that these could be separated so as to admit of the stricture being divided, and even after this had been done, there were remaining strong adhesions, which occasioned much embarrassment, and resisted for a long time every attempt to divide them. The hernia was ultimately reduced, but the bowels did not act in spite of enemata, and the third day after the operation sickness, with fæcal vomiting, supervened. Five days afterwards, the intestine ruptured, and an artificial anus was formed, which continued patent for rather more than three months, when evacuations again took place per anum; after which the fæces were discharged, in part by the natural, and in part by the artificial anus, the latter gradually closing. *** The persistance of the constipation in this case, with the supervention of fæcal vomiting, and the ultimate formation of an artificial anus, naturally leads us to suspect that the strangulated intestine was reduced without the entire division of the stricture.

Affections of the Bursæ.—Mr. Johnson reports several cases of diseased bursæ from St. George's Hospital; of these, there are instances of inflammation and suppuration of the bursa between the olecranon and skin, which, he says, should be treated by leeching and antiphlogistic measures, to prevent suppuration, and when that state is established, an early and free incision should be made into the bursa and cellular tissue beyond it. Instances are also alluded to, in which other bursæ, situated about the ham, were complicated. In a subsequent report a case, entitled disease of the bursa beneath the tendon of the psoas-iliac, counterfeiting disease of the hip-joint, is recorded by Mr. Johnson. The patient was a surgeon, who was supposed to suffer from disease of the hip-joint, resulting from rheumatic inflammation. When seen by Mr. Johnson, he complained much of pain, referred to the front of the hip and groin, much increased by motion, and consequently by exercise; lameness existed, partly from pain, and partly from stiffness about the joint; the limb was wasted, and the patient thought it rather shortened; the health had also suffered. Mr. Johnson, on examining the limb, found just below Poupart's ligament, and evidently deeply seated, an obscure, but yet not undefined, swelling over the capsule of the joint. It felt, as far as it could be made out, flattened, oval, and not free from tenderness when handled. This was the seat of pain, and this Mr Johnson suspected to be the seat of disease. Striking the head of the femur forcibly against the acetabulum, or flexion or eversion of the limb, did not produce pain, showing that the articular cartilages were not diseased, but extension or violent dragging the limb so as to pull the bone from the socket, and exert traction on the capsule, or forcible inversion of the foot, or eversion or flexion of the foot, made by the patient himself, caused pain, which was referred to the front of the joint—the site of the tumefaction. The disease, therefore, was regarded by Mr. Johnson as being an inflamed, thickened, and enlarged state of the bursa lying between the capsule of the joint and the tendon of the psoas-iliac muscle, and in this opinion he was confirmed by Sir B. C. Brodie. The plan of treatment that was decided on was the application of repeated blisters to the groin, followed up by Scott's bandage; the exhibition of colchicum, combined with sarsaparilla; regulation of the secretions, the use of flannel, very moderate exercise, and careful diet. The result proved, or seemed to prove, the correctness of the diagnosis. The pain gradually became more bearable, and greatly diminished or altogether ceased. The patient died afterwards of some visceral disease. The narration of this case is followed up by the details of a case of lumbar abscess, which, prior to the occurrence of suppuration, was mistaken for hip-disease. Mr. Johnson recognised the nature of the case by the absence of pain on forcing the head of the femur into the socket, on flexion of the thigh, and on eversion of the foot, when made by himself; by its presence when he extended the thigh or simply pulled it down, or inverted the foot, and by equally decided pain when the patient himself flexed the thigh or everted the foot. The pain was referred to the front of the joint, but in some of the movements, especially when the thigh was rudely extended, or inverted, or dragged down, an obscure uneasiness about the spine was acknowledged. These symptoms were regarded by Mr. Johnson as conclusive evidence of spinal disease, shown by the pain excited when the psoas and iliac muscles were subjected to traction, which would be communicated to the vertebræ by those muscles. The results of the case proved the correctness of the diagnosis.

Rupture of the Tendo-Achillis.—Mr. Miller narrates a case of rupture of this tendon, which he treated by bandaging, and the use of the egg-splint. His patient was enabled to walk three weeks after the accident with the assistance of a crutch and a stick, and Mr. Miller attributes his being able to do this to the use of the egg splint. In our opinion, it was scarcely advisable that the patient should have been permitted so to do; a risk of renewal of the rupture was incurred by it.

Disulphate of Quinine.—The following test for the adulteration of disulphate of quinine is recommended by Dr. Nevins, of Liverpool, on account of its delicacy and simplicity:—To one or two grains of the suspected salt, add three or four drops of sulphuric acid, in a white evaporating dish, and twice as many drops of water. If the salt contains either fatty matter or starch, these will remain; whilst, if they are absent, the whole will be dissolved. Let heat be next applied to the solution, and as it becomes concentrated, the acid will char any sugar which may be present, which will be indicated by a black stain round the edge of the solution, and the whole will speedily assume the same colour. By this means, one or two per cent. of organic matter may be recognised in as many minutes without trouble. It is said that salicine is an occasional adulteration; if present, it will be detected by the same proceeding. If a very minute quantity only is mixed with the quinine, blood-red points, and ultimately a general reddish colour, are produced as the concentration proceeds. It is a good plan to observe the effect of the sulphuric acid before the addition of water, as it acts upon the salicine cold, producing the blood-red colour. Thus the single test of sulphuric acid, diluted and heated, detects nearly every impurity which is found in the disulphate; for starch, fatty matters, and insoluble earthy salts, are left undissolved before the application of heat, and salicine, gum, and sugar, are shown by the effects of heat on the solution. Pure disulphate of quinine is not affected by sulphuric acid applied as above.

Displacement of the Uterus.—Dr. J. Hall Davis narrates a case of parturition, which was complicated by a peculiar displacement of the uterus; the position of the uterine neck being that which occurs in retroversion of the womb, the hollow of the sacrum, however, being occupied, not by the fundus, as in cases of that mal-position, but by a portion of the posterior walling, extended and developed in that direction, apparently at the

expense of the lower or vaginal section of the uterus, which had not undergone that amount of development, with obliteration of the cervix, proper to the full period of gestation. The labour was completed by the efforts of nature.

Poisoning by Oxalic Acid.—Dr. Ogilvy was called to a lady, whom, when he arrived, he found to be dead. There existed a suspicion of suicide by poisoning; the body was consequently examined after death. The mouth and tongue had a bleached appearance, but not corroded. The brain was healthy, perhaps rather vascular. The heart was slightly enlarged, without perceptible thickening of the walls, but was more heavy than usual—a condition which agrees with Dr Clendinning's remark, that hypertrophy may be found to exist by having recourse to the balance, though it may not be obvious to the eye. There was no rupture of the heart, nor of any vessel connected with it, and no disease of any of the valves. Both ventricles were full of black uncoagulated blood. On opening the abdomen, the liver was much enlarged, and the stomach was in a state of considerable decomposition. The coats were soft and friable, indeed, so easily torn, that when ligatures were applied to each orifice, and the viscus removed, the weight of the contents produced laceration. The neighbouring intestines, and the portion of the left lobe of the liver in contact with the stomach, were similarly disorganised, as if the contents of that organ had transuded and affected them. The stomach was half full of a dark gelatinous-looking mass, the taste of which was intensely acid. On washing the stomach, the coats were found pale, the blood-vessels ramifying on the surface being dark, and filled with coagulated blood, thick, like extract. The cardiac orifice, and lower portion of the œsophagus, appeared as if boiled, the mucous coat being white, and easily detached. The results of the analysis of the contents of the stomach led the experimentalists to conclude that death had occurred from oxalic acid, an opinion which was further confirmed by finding a quantity of that poison in the deceased's bed-room. It seems from the statement made by the family, that this unfortunate female must have taken the poison during the temporary absence of her sister, who, on her return three minutes after, found her dead, showing an extraordinary rapidity of action on the part of this poison.

Fungoid Tumour at the Base of the Cerebellum; Amaurosis.—Mr. Taylor attended a gentleman who, after having been for many years subject to severe head-aches, became affected with dyspepsia when between thirty and forty; and afterwards with flatulence, noises in the head, and total deafness of the left ear. This was followed by lachrymation and muscæ volitantes, and afterwards the eyes became amaurotic. He was seen by Mr. Tyrrell, who regarded the disease as being of cerebral origin. The pupils were much dilated, though still obedient to a strong light, and the globes appeared more prominent and firmer than natural. The headache recurred with greater severity, chiefly affecting the left side of the occiput. A year or two after the eye-sight began to fail, he was attacked with neuralgic pains, commencing in the left sciatic notch, and extending in the course of the sciatic nerve to the outer side of the knee, and down the leg as far as the ankle. The pain, which was agonising, occurred in paroxysms, and seemed to be increased by exercise of the limb, and to subside altogether at night, or in the recumbent posture. The limb wasted visibly, at the same time general emaciation was making progress. In the latter part of the year in which the neuralgia commenced, he had several attacks of delirium, followed by stupor, and ultimately accompanied by clonic convulsions. The wretched man lingered on for many months in this manner, and finally died four years after he first became amaurotic. An examination of the body was made sixteen hours after death. The bones of the skull were thin, and the diploe scarcely visible. The dura mater was healthy, and not unusually adherent. The vessels of the pia mater were much congested, and serum was diffused extensively into the cellular tissue between the convolutions. The brain was exceedingly firm, and on dissection presented a great number of large bloody points. The lateral ventricles were distended with clear serum, of which four or five ounces were collected. The septum lucidum was broken down; the choroid plexuses were shrunk and pale, and had several small serous cysts formed on them. On removing the brain, the optic nerves were observed to be very small, and of firm consistence; on cutting away the attachments of the tentorium, a bulging of it was seen on the left side, and when this was punctured, about half an ounce of gelatinous fluid, of a greenish colour, escaped. The cerebellum was next raised up, and its left hemisphere a tumour was discovered, lying on the petrous portion of the temporal bone, and firmly attached to the auditory foramen. There were also extensive connexion between it and the cerebellum, which was hollowed out to receive it. In attempting to dissect it out, so as to preserve its relations to the cerebellum, the morbid growth was found to have extended some way into the auditory canal, which was widened considerably, and the surrounding bone appeared to be eroded. The tumour, when removed, was an oval mass, compressed from above downwards, and having the following measurements:—Length, two inches, greatest width, one inch and a third, and vertically, one inch. Its surface was lobulated, and studded with small serous cysts, the colour of a darker tint than the brain, owing to the greater vascularity of its coverings; these consisted of the arachnoid membrane and a thin cellular layer, which were continuous with the investments of the cerebellum, forming the only bond of union between them. Situated in the angle between the lateral mass of the cerebellum and its large peduncle, it pressed also on the pons varolii. The seventh nerve, and the divisions of the eighth, passed under it to their respective foramina, without being at all flattened or displaced. A section of the tumour showed a dense structure of glandular firmness, made up of whitish arborescent fibres, leaving numerous interstices, which contained some gelatinous serum. The striæ of white tissue were speckled here and there with black points, which proved to be coagulated blood, and sections of minute vessels. One half was shown to Dr. Walshe, who considered it to be a variety of encephaloid cancer, and rare, as occurring in the membranes, and not in the substance of the cerebellum. In the thorax, the heart was found much enlarged, from dilated hypertrophy of the left ventricle. There were several patches of cartilaginous deposit at the bases of the mitral valves, and the aorta was somewhat dilated at its commencement, but healthy in its valves and lining membrane. Old adhesions existed between the ribs and middle and lower lobes of the left lung; the latter organ was much congested, and the bronchiæ filled with frothy mucus. In the abdomen, there was nothing worthy of notice beside the kidneys, which were in an advanced stage of granular degeneration.

Strangulated Hernia.—Dr. M'Egan writes to state that his experience is in favour of the use of opium in the treatment of strangulated hernia.

Fellows of the College of Surgeons.—Dr. Waddy states that one of these gentlemen, by whom the honour and dignity of the profession is to be upheld, has offered himself as surgeon to a sick-club, to supply them with medicines and attendance at two shillings per head per annum; and he adds that one of the gentlemen selected by the council of the college for the fellowship, had left the profession for several years, and was, when elected, an eminent country banker.

Urinary Calculi.—When speaking of the formation of urinary calculi, Liebig says, uric acid is always present to a small amount, in the normal urine of man. It is partly to its presence that this fluid owes its well-known acid reaction. In unhealthy conditions of the organism, the proportion of uric acid in the urine is greatly augmented, and accumulating in the bladder, it gives rise to the formation of stones, or calculi. But, in addition to uric acid, there are other matters which enter into the composition, or altogether constitute those concretions, and amongst these there are two organic substances particularly deserving of a minute consideration—namely, cystic oxide, and xanthic oxide, or cystine and xanthine. Calculi consisting of uric acid, and the urates are produced by the deposition of the solid matters contained in the urine, when it is overcharged with them, or when it has been retained too long in the bladder. Calculi may, however, be formed, when neither the proportionate amount of solid matter in solution is increased, nor the fluid retained a longer time than natural in the bladder, because the urine may, from various causes, undergo such a change in its constitution, that those conditions essential to the solubility of certain compounds may be absent, and consequently these compounds necessarily become precipitated. Phosphate of lime is perfectly insoluble in pure water; its solubility in urine depends upon the existence of free acid in that fluid. If, from any cause, the urine becomes alkaline, as, for instance, when organic salts with alkaline bases are taken into the stomach, which, as is well known, are converted into carbonates during their passage through the organism, then the conditions essential to the solubility of phosphate of lime are removed, and this salt is precipitated. All calculi consisting of phosphate of lime are produced in this manner. The calculi containing ammonio-magnesian phosphate are also produced in a manner precisely analogous to this. In many animal fluids, particularly the urine, phosphate of magnesia is found in solution. Normal urine contains no ammonia, but when, from any cause, ammonia is generated, the phosphate of magnesia no longer remains in solution, but is precipitated as ammonio phosphate of magnesia. Beside the foregoing, there is another cause of the formation of urinary concretions. In diseased conditions of the system, peculiar compounds are not unfrequently formed which are never produced in the healthy organism, and being perfectly insoluble in urine, are immediately deposited in a solid form from that fluid. In this manner oxalate of lime calculi are formed, and those concretions of organic matter termed cystic oxide and xanthic oxide. But beyond these chemical causes of calculi, certain mechanical conditions have almost always more or less influence upon their formation in the urinary bladder. When any of these states which have been enumerated exist, and, in consequence, deposits occur of uric acid, urates, insoluble phosphates, oxalate of lime, &c., in small quantities, it does not necessarily happen that calculi are formed, but, in most cases, the urine flowing off, carries with it through the urethra the sediments suspended in it, or already deposited. When, however, the bladder contains mucus, these sediments are apt to adhere to it, and become united into masses. Very often a foreign body, which has accidentally got into the bladder, forms the nucleus upon which these sediments are deposited, and to which they adhere; the irritation they occasion on the internal surface of the bladder induces the secretion of mucus in which the urinary deposits accumulate, and they thus become the direct cause of the formation of calculi.

EXAMINATION FOR THE FELLOWSHIP OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Anatomy and Physiology.—*Senior Candidates.*—(August 5th.) 1. Specify the several bursæ in the neighbourhood of the knee-joint? 2. Describe the course of the tears into the nose, and the structures met with in the eyelids. 3. What veins form the vena portæ, and from what organs is its blood derived? 4. What vessels enter, or come out of the transverse fissure of the liver, and what is the use of the longitudinal fissure? 5. Where do the spermatic veins, the bronchial veins, the Vena Magna Galeni, and the coronary vein of the heart terminate? 6. Give an account of the peculiarities of the fœtal circulation. 7. Enumerate the muscles of expiration and inspiration, and explain the effects of respiration on the blood, and the changes produced by it in the air taken into the lungs.

Junior Candidates.—1. From what sources is the dura mater of the brain supplied with blood? 2. What are the most remarkable peculiarities of the dura mater of the spinal cord, and in what respects does it differ from the dura mater within the skull? What purposes do the orifices in its sides serve, and what is interposed between them? What does

it adhere to anteriorly, and what parts intervene between it and the vertebræ laterally and posteriorly? 3. What nerves supply the tongue; to what particular part of it is each distributed; and what is the function you would assign to each of them? 4. Is there any correspondence between the fifth cerebral nerve and the spinal nerves in their mode of origin? 5. Which of the cerebral nerves are voluntary nerves, and which nerves of sense? 6. What nerves supply the skin and muscles of the eyelids? 7. What are the peculiarities of the blood-vessels of the brain, and how is the circle of Willis formed? 8. How would you account for the cessation of the action of the heart and the functions of the brain and nervous system in the different forms of asphyxia? viz., by strangulation, submersion, and suffocation.

Surgery and Pathology.—*Senior Candidates.*—(August 7th.) 1. Describe the operation for a strangulated oblique inguinal hernia of moderate size. 2. Describe the *post mortem* appearances usually noticed in persons who die of a strangulated hernia, or after the operation for it. 3. Enumerate the textures and parts divided in a circular amputation of the thigh, at the junction of the lower with the middle third of that part of the limb. 4. Mention the general rules applicable to the treatment of wounded arteries. 5. What is the best mode of arresting venous hemorrhage? 6. How would you distinguish a hernia from a hydrocele, a swelling of the testicle, and a varicocele? 7. Under what circumstances would you advise amputation for a compound fracture of the leg, in the early and more advanced stages of the case? 8. If judged proper to attempt to save the limb, what are the chief indications in the treatment?

Junior Candidates.—Describe the parts concerned in femoral hernia; the characters of the swelling; the diagnosis from other tumours liable to be mistaken for it; and the operation for it in the strangulated state. 2. Enumerate the principal differences between scirrhus and fungus hæmatodes, or medullary cancer. 3. Give a description of scirrhous cancer of the female breast; specifying what textures and organs are often involved secondarily; and the circumstances which should interdict the operation of removing the breast. 4. Describe the process by which broken bones unite, through its several stages. 5. Describe the process by which nature sometimes brings about the cure of an artificial anus, and the surgical means for promoting this object. 6. What is the state of the blood-vessels and the circulation in a part affected with phlegmonous inflammation, according to its degree and stage? 7. Explain the symptoms, consequence, causes, and treatment of phlebitis. 8. Under what circumstances may the pulsations of a popliteal aneurism spontaneously and *gradually* cease; or, in other instances, be *suddenly* reduced, and even stopped, attended with increased swelling, discoloration, and fall of temperature in the leg and foot?

MISCELLANEOUS CORRESPONDENCE.

The Altered Bill.—The thrice-amended Medical Bill, Sir James Graham's great-grandchild, is now before the profession in its printed form, and enables us to hazard a conjecture whether the same bill, or (to use an Hibernicism) *the same bill amended for the worse*, will have a better chance of success next Session of Parliament, than it has had in the past. We were certainly led to believe, by Sir James's closing speech, that the secondary examination, however unpalatable in itself, would at least convey the surgical title; yet no promise of this kind is repeated in the bill, which, on the contrary, degrades the general practitioner from his present position by denying him the slightest pretension to the name or duties of a surgeon, *even though he should possess the fellowship of the College of Surgeons* (Clause 33). The secondary examination is either a mere pretext to extort money, or it tacitly implies that the general practitioners are too ignorant to be entrusted with the education of their own class—an imputation to which it is not likely that they will patiently submit. The subject of the Council of Health is most studiously mystified. That there is to be a Council of Health, and that it will be composed of twelve members appointed by the crown, is evident; but who those members are to be is not announced. Hence a suspicion may be justified, that the council, once established, with Sir James Graham as its president, it may be difficult for the general practitioner to find a seat at its board, should the influence of the favoured colleges be directed to oppose his reception. We glean, also, from the statement of Sir James (for it is not "down in the bill," and is probably one of the screw-powers vested in the Council of Health), that every future general practitioner will have to pay £20 to the Colleges of Physicians and Surgeons; the latter not being required to pay one fraction of a farthing to each other, or to the College of General Practitioners. One half of this sum is to be levied to support the library and museum of the College of Surgeons, with which the future general practitioner is to have little or nothing to do; whilst it is taken for granted, that the new college will not require any considerable amount of funds for the support of its own museum, library, or botanical garden. Is Sir J. Graham so astounded by the jackal cry raised by the College of Physicians, as they join the pack in chase of the general practitioner, that he feels compelled to cast them a share of the spoil to the amount of £5 5s. a victim?—and does a similar impulse lead him to permit the council of the College of Surgeons, like foul-feeding vultures, to cling to their prey to the last, and to maintain a deceptive and sordid union with those whom they have endeavoured to drive from their doors with insult and injury? The college council have asserted, with a boldness of assertion peculiar to themselves, that we do not require their diploma, but seek it only for the honour of their names attached to it! Vain triflers! Do they not know, or *will* they not know, that the most unimportant surgical appointment, either at home or abroad, cannot be obtained without *a* surgical diploma? And when the general practitioners propose to decline the honour of their names and connection, and to be content with their own legally-recognised surgical certificate, what do the college council? Why they hasten grumbling to the Government, and demand protection and the power to keep them—they do not say "the College of Physicians may have them and welcome." Without detracting from the merits of physicians and consulting surgeons, or questioning the utility of their respective positions, we cannot desist from requiring them to "give unto Cæsar the things that are Cæsar's." Let them retain their dignity unsullied, let them move in their own exalted sphere, and let the general practitioners, like satellites, revolve around them; but if they will not borrow light from us, let them at least abstain from borrowing money. I contend that we should most vigorously struggle for the independence and integrity of the College of General Practitioners; and for its power to qualify its members for all the duties they are destined to perform, whether surgical or otherwise. Deprived of the power to qualify in surgery, the New College can be but a college of apothecaries; and deprived of a surgical title and diploma in his own right, the general practitioner can be, under whatever name, no more than an apothecary. The present position of the general practitioner is not so unfavourable that it demands any hurried or hazardous alteration. In fact, it were difficult to say what he essentially requires that he does not already possess, except it be a more respectable home and name than the Apothecaries' Hall can afford, and a consolidated examination in medicine and surgery, to avoid the evil of resorting to two institutions for his perfect qualification, with the option of evading either as his convenience may prompt. Should, therefore, no more advantageous terms be obtained than those hitherto offered, it would be wise to remain as we are, and not dethrone king Log until we are pretty certain that his successor will not be king Crane. for, as long as Sir James Graham continues to dramatise the tale of the Old Man and his Ass, and in trying to please everybody pleases nobody, and loses his bills into the bargain, so long we can never hope for a happy issue out of all our afflictions.—A Practitioner with Two Tails.

Hysteria and Prostitution.—I should feel obliged by your publishing my protest against an erroneous dogma which appeared in the *British and Foreign Medical Review*, for July last, at p. 32, line 22. The reviewer states, that "prostitutes are not hysterical." This statement is utterly opposed to my experience, and I believe to that of all Lock Hospital surgeons. I recollect many years since, in going round the wards of a Lock Hospital, noticing a girl in a strong hysterical paroxysm, and on directing the attention of the medical attendant (Dr. Cumins) to the case, he emphatically said, "This is the field (that is a Lock Hospital), for studying hysteria." As an erroneous assertion, coming from a grave quarterly, might influence an inexperienced practitioner in the treatment of the disease, and also lead to wrong views as to its pathology, I think it ought to be publicly contradicted.—Scrutator.

Half pint of beer at 4 p.m; 5 oz. bread per diem.

Estimated weekly charge, 9s.; the Devizes, 8s. Answer returned—see 54th, clause 8 and 9 Vic., c. 126, Aug. 8, consequently if the visiting justices made the proper order in the cases, the guardians of unions have no discretion, and the different officers will be bound to obey.—*From a Correspondent.*

REVIEWS.

On Cataract, and its Appropriate Treatment by the Operation adapted for each Peculiar Case. By CHARLES GARDINER GUTHRIE, Assistant-surgeon to the Royal Westminster Ophthalmic Hospital. Churchill. 1815.

A Practical Treatise on the Diseases of the Eye. By WILLIAM JEAFFRESON, late Surgeon to the Bombay Eye Infirmary. Renshaw. 1814.

Our readers are already acquainted, in a great measure, with the contents of the first volume in our list—to those who have carefully perused the valuable lectures on cataract by the Messrs. Guthrie, which were published in the columns of this Journal during the past winter, not a word of commendation need be said on the merits of a practical work based upon those lectures. To the numerous subscribers, however, who have joined us since that period, it may be requisite to observe, that in this work will be found, combined, the results of the experience of the veteran oculist, and of his son, the one long since enjoying an European reputation as a surgeon and as an oculist, and the latter fast attaining an enviable pre-eminence in his profession. It cannot be doubted, therefore, that the work is one of great value, of which a careful perusal of its pages will at once convince the intelligent reader. To every man desirous of acquiring a thorough knowledge of the present state of medical science as regards cataract, we can safely and honestly recommend it. The author is an operator of exceeding skill, coolness, and dexterity, and will, doubtless, take a high position as a surgeon and surgeon-oculist.

Neither our space nor the length of time which has elapsed since the former notice of Mr. Jeaffreson's work appeared, will permit of our indulging in a lengthened review of it at present. We owe consequently both to our readers and the author, our best apologies for the unintentional neglect. The surgeon who would consult Mr. Jeaffreson's work for information, in the belief that it is a systematic treatise on the diseases of the eye, would find himself mistaken. It must be regarded as the record of personal experience only. While, therefore, it will not replace the more elaborate and complete works of Mackenzie, Tyrrell, Middlemore, Lawrence, &c., it will serve as an exceedingly useful adjuvant to their study, and the surgeon who is already acquainted with ophthalmic medicine, will derive both instruction and advantage from its perusal. The constitutional origin of many diseases of the eye is referred to, by Mr. Jeaffreson, in a manner, we should think, to carry conviction to the mind of the reflecting practitioner; if his doctrine in this respect were more attended to, the result would be advantageous alike to the surgeon and the patient.

GOSSIP.

THE MEDICAL TIMES.—We are glad to observe that the public spirit of its proprietary is properly appreciated by the profession, who have come forward with a subscription to defray the expenses of an action for libel lately decided against them at the suit of Mr. Wakley, M.P., Coroner, and Editor of the *Lancet*, who conceived his character affected to the extent of £2,000, but which the jury reduced to £150. As a valuable and impartial record of all that is going on in the medical profession, we recommend this periodical to its members.—*Sheffield Iris.*

APOTHECARIES' HALL. — Gentlemen admitted Licentiates on the 28th of August, 1845:—Richard Gillard, Alfred Stephens, William Withers Moore, Thomas George Wrench, William Waind, William Symington, George Dawson Nelson.

Dr. James Cowles Prichard, of Bristol, has received the appointment of "Medical Commissioner in Lunacy," in place of Dr. Henry Herbert Southey, resigned. The appointment was in the gift of the Lord Chancellor.

OBITUARY.—We regret to record the death of Dr. Robert Graham, Professor of Botany in the University of Edinburgh, which took place near Stirling on the 7th of August last, after a protracted illness.

EDINBURGH UNIVERSITY.—We learn from the *Northern Journal of Medicine*, that the following gentlemen have received the degree of M. D. in this university: *Of Scotland*—William Aitken, on the influence of vaccination on the prevalence and severity of small pox; James Anderson, on scrofula; Henry Arnot, on the physiology and special pathology of asphyxia; Alexander Laing Begle, on diseases of synovial membrane; James Braid, on diseased nutrition; George Brewster, on inguinal hernia; William Alex. Bryden, on intermittent fever; Alex. Forrester Calder, on typhus; George Fenton Cameron, on insanity; Mathew Combe, on the diagnosis and treatment of diseases of the knee joint; John Robert Dickson, on uterine hemorrhage in connection with pregnancy; John Dunlop, on the influence the mind exercises over disease; James Ellison, on bronchotomy; Thomas Fraser, on inflammation of bone, and certain pathological conditions which arise from various stages of the process; Wm. Tennant Gairdner, on death; James Donaldson Gillespie, on the reproduction of bone after necrosis; John Grant, on hemorrhage, accidental and unavoidable; James Adam Hunter, on aneurism; Lawrence Ramsay Hynd, on the influence of vaccination on the prevalence of small-pox; James Keith, on the inflammation of the cellular tissue of the pelvis; Andrew Legat, on hydrocele of the tunica vaginalis; John Mackay, on the principal forms of serous effusion, and their causes; David Mackintosh, sibbens identical with the exanthematic group of venereal diseases; James Innes Macintosh, on the effects and indications of blood-letting in inflammation in general; Daniel Maclachlan, on the croup; William Main, on tobacco; George Augustus Mein, on scarlatina; Brinsley Nicholson, on the coagulation of the blood; John Pirie, on tubercle; James Hunter Robertson, on the induction of premature labour; John Struthers, on the physiology and physiological anatomy of the muscles and nerves of the eyeballs, and on the theory of their derangement in strabismus; George Thomson, on the general doctrines of dropsy; Robert Wilson, on pulmonary tubercle.—*From Berwick-upon-Tweed:* David Fr. Sitwell Cahill, on diabetes mellitus.—*From England:* William Henry Addison, observations on some few subjects connected with midwifery; Charles David Arnott, on aneurism; James Heaton Bennett, on fever; Robert Addison Byers, on the saliva and gastric juice; Henry Crookenden, on the structure and diseases of bone; Richard Domenichetti, on functional diseases of the liver; Ray Charles Golding, on chronic diseases; George Haworth, on tobacco; John Hutchings Jerrard, on surgical hemorrhage; Alfred Sinclair Kingdon, on delirium tremens; James Logan, on the particular symptoms occurring in phthisis pulmonalis; Charles Martin, on digestion; Robert Thomas Marland, on nutrition; James Henry May, on delirium tremens; Samuel Nicholson, on delirium tremens; John Greenway Overton, on the diseases of the larynx and trachea; John Watson Pacey, on gunshot wounds; George Hutchinson Ray, on intermittent fever; Henry James Stokes, on dropsy; Thomas West, on intermittent fever; Thomas Wright, on voltaic electricity and electro-magnetism, and their application to the cure of disease.—*From Wales:* John Roberts, on the influence of temperature on the health of man; George Charles Stacpoole, on the correct method of examining patients and observing disease.—*From Ireland:* Alexander Tod Anderson, on inguinal hernia; John Barclay, on syphilis; Thomas Crawford, the history, causes, pathology, and treatment of paralysis; Richard Dill, on dyspepsia; Gerald Fitzgerald, on the nervous system; John Hutchinson Garner, observations on birds; George Johnston, on hypertrophy of the heart; George Hugo Kidd, on vaccination, its protective power, and the proofs of the necessity of re-vaccination; Robert Wallace, on the symptoms, pathology, and treatment of rheumatism.—*From the Isle of Man:* John Robert Oliver, on chlorosis.—*From Berlin:* Fred. Geo. Wm. Müller, on the signs of pregnancy—*From Canada:* James Stephen Hackett, on asphyxia; Hector Peltier, des retrecissements de l'urethre—*From Nova Scotia:* James Allen, on the principal deformity of the pelvis in relation to parturition; Daniel M'Neill Parker, on the mechanism and management of parturition.—*From Barbadoes:* George Frederick Bone, on yellow fever; William Alleyne Nicholson, on the particular forms of death, more particularly the anatomical signs of syncope.—*From Bermuda:* Samuel Reeve Tucker, on the cure of aneurism.—*From Prussia:* Solomon Edward Casperson, de galvanismo in paralysi adhibendo.—*From the East Indies:* Edward Barons Bowman, on gangræna senilis; William Judson Van Someren, on the causes of difference in the facility of parturition in the different races of man. The annual prizes of the Medical Faculty, being gold medals of equal value, given to the authors of the best thesis among the graduates of each year, were conferred upon—Drs. William Tennant Gairdner, of Edinburgh; George Hugh Kidd, of Newry, Ireland; David Mackintosh, of Inverness-shire; Brinsley Nicholson, of Inverness-shire; Dr. William J. Van Someren has obtained the gold medal in the class of medical jurisprudence.

Reports have reached us from various quarters that the potatoe crops throughout the country have failed, the potatoe having rotted very extensively even while in the ground. The cause of the destruction of this valuable esculent is said to be the encroachment of a worm, not at present well-known to naturalists. Meetings have taken place in various parts of the country, more especially in Surrey, to take this matter into consideration, at which it has been plainly stated by some of the medical men who have attended them, that the potatoes, in consequence of the injury they sustained, have been rendered injurious to health.

FISSURE OF THE NIPPLE.—In the Obstetric Hospital at Padua, fissures of the nipple occurring in nurses are treated in the following manner:—Suckling is suspended; the nipple is covered by compresses, frequently dipped in a mixture, consisting of a few drops of tincture of arnica montana in distilled water, and small doses of sulphur are administered internally. The cure is rapid, and in a short time suckling may be recommenced.—*Annal. De Therapeut.*

MORTALITY TABLE,

For the week ending August 30, 1845.

Causes of Death.	Total.	Average of 5 summers	5 years.
ALL CAUSES . . .	835	904	963

No. 312. SUMMARY. Sept. 13.

CLINICAL LECTURES ON SURGERY.

BY M. F. LALLEMAND.

Translated for the Medical Times by JOHN WATERS, M.D. M.R.C.S.E., Ancien Eleve des Hôpitaux, Membre de la Société des Medecins Etrangers, &c. &c.

CASE.—*Discharge from the Rectum; Redness of the Anus previous to the Age of Seven; various Modes of Treatment without success; Antivenereals; Recovery.*

Henry L——, seven years of age, had from his infancy a redness of the anus, as well as an ichorous discharge, which assumed an intermittent type. By an attentive examination, the presence of intestinal worms in the fecal matter could not be detected, nor was there fissure of the anus. The weak and delicate constitution of the child did not improve under the use of anthelmintics, antiscrofulous remedies, or sulphurous baths, &c., which were prescribed for him by the different physicians under whose care he was placed. The father had led a dissipated life when a young man, and a short time before marriage he was obliged to undergo a specific treatment for exostosis, which was attended with osteocopic pain; the mother never had any trace of a venereal affection. It was supposed that the child was labouring under a congenital affection, and sublimate baths were prescribed, which proved so successful that an antivenereal treatment was commenced internally, and this obstinate affection soon gave way under its influence. The child is now twelve years of age; he is tall and vigorous, and never feels uneasiness in the region of the rectum; his constitution, which was so impaired, is now fully restored, and his sight, which was formerly very weak, is now excellent.

We must admit that this affection was syphilitic, as it yielded so quickly and completely to the antivenereal remedies, and had resisted for seven years every other mode of treatment. It had not been communicated by the mother, as she never had the slightest appearance of the disease; consequently, it was only from the father that the seeds of this congenital syphilis had been transmitted to the child with the first elements of life, which goes far to prove that fecundation does not consist solely in a vital excitation of the ovum.

CASE.—*Cutaneous Eruption; Profuse Leucorrhœa at Puberty; Antivenereals; Recovery.*

A young girl, sixteen years of age, had, before the period of puberty, ephelidæ, which extended all over the skin; her sister, who was some few years older, had, when, of the same age, sore throat, as well as a profuse leucorrhœa. The father, in his younger days, had led a dissipated life, and had contracted several venereal affections, of which there were now no traces left: the mother never had been infected. An antivenereal treatment was given to the two sisters, and all these symptoms quickly disappeared, which proved that the opinion given in this case was correct.

Syphilis, when observed among children, may then be communicated in different ways; for instance, the mother may be infected towards the end of her pregnancy, and the child will only contract the infection during accouchement: in these cases, the symptoms show themselves particularly in the parts in contact with the diseased surfaces of the mother, and then they appear shortly after the accouchement. These cases are too numerous to deserve any notice being taken of them here.

If the mother has been contaminated, either before her pregnancy or at its commencement, she may not present the local symptoms at the period of her accouchement, and, notwithstanding, may give birth to a diseased child. There is not then a transmission of the syphilitic virus by direct contact in this case; it is given to the fœtus by the materials of nutrition, which are carried from the mother: the affection is then constitutional from the commencement, and shows itself at some period more or less remote. The mother may have been treated more or less regularly, and the local symptoms may disappear, notwithstanding which, the child may, at a later period, show the characters of a constitutional affection. But it is not the same in these cases as in the direct infection from the parts in contact with the genital organs of the mother, where the traces of the disease are to be found; but in parts not in contact with the vagina, these ulcerations are more frequently found, such as on a mucous membrane, or on some portion of the skin continuous with it, at the margin of the anus, the scrotum, the lips, or under the axilla, &c. Although the mother may be protected from consecutive symptoms, and be radically cured, the treatment may have been begun too late to protect the fœtus; and at some period, sooner or later, we see constitutional symptoms come on in the child. Sometimes it happens that consecutive venereal affections come on in children, without any syphilitic symptom showing itself on the side of the mother; the father must then be considered as having transmitted the infection *directly*, without affecting the mother. These consecutive symptoms are generally very superficial, and not attended with danger; they consist in slight cutaneous affections, sore throat, and sanguineous injection of the eyes, &c. They, however, require an antivenereal treatment. This last point, also, proves that the seminal fluid acts in a material manner in the act of fecundation, and does not only produce a simple excitation in the ovum, like that of the electric fluid, but that the semen contributes an important part in the composition of the fœtus, since it can procreate children who, in later years, will be infected, without the mother ever having been diseased.

SECONDARY FORMS OF VENEREAL AFFECTIONS.

CASE.—*Chancre under the Prepuce; Carelessness of the Patient; Pustules on the whole Surface of the Body; Divers Modes of Protracted Treatment; Recovery.*

Michael Peyre, a soldier in the 3rd regiment, came to the hospital on the 4th of March, 1845, having a chancre under the prepuce. The skin was indurated about the ulcer, and of a scirrhous appearance; the sebaceous matter which is secreted round the glans had accumulated in this space, and the sanious secretion which came from the ulcer remained also in contact with the glans. Excision of the prepuce was deemed necessary, but the patient would not consent to the operation, as he said he could henceforth keep the parts cleaner. The pills of Sedillot were given, and when he had taken about fifty of them, the chancre (to which also mercurial ointment was applied) cicatrised. The treatment was, however, continued until he had taken one hundred and forty pills. About this time some large pustules came out on all the body, even on the face; the pain was excessive; the skin was of a yellow icteric tint, and he grew daily more emaciated: it was then considered necessary to change the treatment. The iodide of potassium was given instead of the pills of Sedillot. At the expiration of one month, some preparations of gold were tried (the hydrochlorate of gold in solution, and oxide of gold rubbed on the tongue). Emaciation continued notwithstanding the employment of these measures, with a cadaveric appearance, and extreme weakness: the profuse suppuration, and the fetid odour which was given from the pustular crusts, all induced the fear of his speedy dissolution; he was then moved from the venereal ward into a ward for the wounded. When his bed was changed, a great number of pills were found concealed in the palliasse: this discovery soon explained the obstinacy of his disease and its severity. But the unfortunate being could not be left to his miserable fate. The iodurets and the preparations of gold produced no improvement; the pustular crusts extended, and became much thicker; blood was continually oozing from them, and it was then considered necessary to have recourse to mercury. The alimentary canal being so weakened, it could not be given internally, but baths containing the mineral were used, and with some prospect of success, as the disease was of a cutaneous nature. The sublimate was preferred, and the quantity was gradually increased from four to sixteen gram. in each bath. These were alternately changed for bran baths, to allay the general irritability, and at the same time the patient was allowed a mild but invigorating diet. Under the influence of these means, the face soon became smooth, the ulcers healthier, and the numerous wounds on the legs and thighs put on an appearance of cicatrisation. He took altogether about one hundred baths, and occasionally the preparations of gold. About the month of November, 1845, the iodide of potassium was again used, but the patient becoming tired of so many ineffectual attempts for his recovery, all medicaments were discontinued, and the wounds were merely dressed with mercurial ointment; from the month of January, 1844 to the month of June in the same year, simple cerate was only used. Gradually the face looked better, also the immense ulcers on the legs, trochanters, on the lumbar region, &c., and six months after, having left off all treatment, these ulcers were completely cicatrised, and Peyre was sent to the sea-side to insure his recovery.

The indocility of this patient must be considered as the cause of the frightful secondary symptoms which showed themselves in the case. To avoid such mistakes, from that period, I resolved to substitute the liquor of Van-Swieten in similar venereal cases for the mercurial pills. Although this mercurial has its inconvenience, it possesses one great advantage, which is of paramount importance in

hospital practice, namely, that the patient can take the medicine in the presence of the nurse.

Cases of this kind, unfortunately, are not uncommon, particularly in hospitals, in consequence of the prejudice which is now so popular, that "mercury" remains in the tissues, and produces the most deleterious effects, from which the economy can never recover: it is for this reason, that when the primary symptoms have disappeared, the patient becomes impatient, and refuses to take further medicines, or conceals them in his bed, as in the case just related. The history of this case was the means of discovering in the venereal wards many persons who acted in a similar manner. The nurses affirmed, however, that they had taken their pills, but they contrived to elude all vigilance by concealing them in some part of the mouth, and merely swallowed the tisane, and afterwards threw away the pills. To avoid repetitions of this kind, the most minute surveillance was put in force. We can easily understand how irregular the statistic researches must be in this method of treatment, and how guarded we should be in drawing conclusions from the reports of cases where frequent relapses take place, although a mercurial course had been apparently most strictly attended to. This fraud is also supported by certain new theories, which are placarded on all the walls, and which tends to give an invincible repugnance to the use of mercury. The many cases of relapse, which are the consequence of these erroneous ideas, become more frequent, and appear to favour their theories; but it is a fatal error to those who are victims to such a formidable disease; and its numbers must increase, if we do not minutely consider the primary cause of the relapse, that is to say, we should ascertain the nature of the specific treatment. Patients are not, however, always to blame, for sometimes the treatment is too soon discontinued, even by the surgeon's orders; but when carefully administered, "mercury" does not expose the patient to greater danger than other therapeutic substances which are daily prescribed.

CASE.—*Constitutional Syphilis reappearing after several incomplete Methods of Treatment; Death.*

A military infirmier, forty years of age, came to the hospital of Saint Eloi, in the month of April, 1844. Six years previously, he had contracted a discharge which he treated for forty days with Chossart's mixture, but without success. At the end of six months, his blenorrhagia still continuing, he had connection with a diseased person, and immediately afterwards two buboes appeared, which were merely opened, and afterwards covered with emollient poultices, and they soon healed. Two years afterwards, a squamous eruption came in the lumbar regions, the head, and right leg, also a large chancre on the prepuce, which continued for eleven months.

The patient was of an ardent temperament, and gave way to his desires, the result of which was fresh buboes that suppurated. Applications of Goulard water and aromatic wine were used, but with no success; however, cicatrisation took place a year and a half afterwards, by repeated cauterisations with the nitrate of silver. At this period he took mercurial pills, which he threw away, as well as the sudorifics that were offered to him. When he came to St. Eloi, two large ulcerations—the first came on eighteen months before—had made great ravages on the external ileo-femoral region. He was alternately attended by me and M. Serres, and for four months he took the solution of hydrochlorate of gold, sublimate, and aromatic baths; but the treatment could not be persevered in, and the wounds were simply dressed with mercurial ointment. Exhausted by a profuse suppuration, this unfortunate being died in the extreme of marasmus eight months after his coming to the hospital. It may be supposed that venereal affections are not so fatal, however, as we have just seen; when they are neglected or badly treated, they produce as fatal an effect as they did formerly.

CASE.—*Venereal Affections; Leproid Alteration of the Skin, particularly of the Face.*

Aurich, a weaver, from Mahon, forty-two years of age, had frequent attacks of blenorrhagia and syphilis, which he had neglected. He came to the hospital of St. Eloi on the 5th July, 1845. His face, legs, and hands, were frightfully disfigured by an enlargement of an "elephantiac" appearance, which continued for five years; his feet and legs were of an extraordinary size and stiffness; the skin was studded with indurated tubercles, and was of a dull brown colour, and covered with innumerable scales. On the hands and feet, particularly in the articular joints, osseous nodosities were seen, which looked like exostoses. The disease was most intense on the face, around the nose, above the eyebrows, and the lobes of the ears had acquired an enormous size; his voice was very hoarse. The prepuce was found to be hypertrophied, hardened, and there were traces of cicatrised chancres on the glans penis. (Circumcision, venesection, pills of Sedillot, sudorifics.) When he had taken about two hundred and fifty pills, he appeared to be much better. It was then I thought of trying the preparations of gold (30 centigrammes of hydrochlorate of gold in solution, 20 centigrammes of the oxide of gold, to be used in frictions on the tongue). In six months' time Aurich left the hospital, if not cured, at least in a much more satisfactory state; his legs and feet had become much thinner; motion was more easy; the engorgement of the hands and feet had disappeared, and the movements of these parts had become more natural; his face assumed a more regular appearance, and lost its hideous aspect. The manner in which the resolution of these tubercles were effected was very remarkable. We sometimes saw a small ulceration, which came on the top of a tubercle; this became covered with a scab, which, at the end of some days, was replaced by a small retractile cicatrix; the small tumour was thus depressed, and the neighbouring skin was drawn towards the cicatrix.

Some authors have maintained that syphilis was the result of lepra, and it is remarkable that, at its first appearance, the venereal disease violently affected the cutaneous surface; but in consequence of the greater care that was given to public hygiene, and the establishment of numerous hospitals for lepers, it prevented this disease from extending its fearful ravages. In this case we observe a consecutive syphilitic affection, which assumed the most hideous leproid aspect, and which rapidly became ameliorated under the employment of antivenereals, notwithstanding its frightful severity.

CASE.—*Extreme Disorganisation of the Face and Scalp; Antivenereals; Recovery.*

X., a drummer, fifty-two years of age, of good constitution, and of a sanguineous temperament, came to the hospital about the beginning of December, 1843. The skin covering the face, and particularly that of the forehead, the ears, and a part of the scalp, was red, tubercular, and had all the appearances of the large "lupus," whigh affects these parts. These disorders had now lasted for six months; the pharyngeal mucous membrane was also engorged, and presented a remarkable injection; the voice was very hoarse. The patient had had many chancres and numerous blenorrhagias. Venesection of 500 grammes, which was to be repeated three times in the space of eight or twelve days; pills of Sedillot, afterwards the liquor of Van Swieten twice in the day. Under the influence of these measures the hoarseness gradually disappeared, the skin became less red, desquamation sot in, and the parts assumed their natural aspect, and in the beginning of February, 1844, the patient left the hospital cured.

This case offers a great analogy to the preceding one, only that the affection was not of so long-standing, and did not occupy the whole surface of the body. It however yielded completely to the use of mercurials.

CASE.—*Chronic Blenorrhagia: Ulceration about the Nail of the Great Toe; Antivenereals; Recovery.*

V., a fisherman, felt pain for a long time around the nail of the left great toe, which had become hard, swollen, and of a violet colour; a profuse suppuration soon came on in this part, and the patient came to the hospital of Saint Eloi on the 12th January, 1844. Repeated cauterisations with the nitrate of mercury were applied around the nail, also to the part from whence this profuse suppuration came, and to the unhealthy granulations. No improvement had as yet taken place, and on the 24th of January the patient told me for the first time of a blenorrhagia which had preceded the disease of the great toe. (Blood to be taken from the arm, leeches to the perineum, infusion of linseed). The pain produced in voiding urine ceased, the antiphlogistic and emollient treatment was continued, and the cauterisation to the nail.

Feb. 14.—No favourable change having taken place either in the urethra or nail, the pills of Sedillot were ordered for him.

March 4.—The toe is cured, and the blenorrhagia has disappeared. Thus we see that the ulceration about the nail and the blenorrhagia depended on a venereal cause. The first affection is so frequent, that it is not necessary to detail other examples of it, and we have spoken elsewhere of syphilitic blenorrhagia. The ulceration which comes around the nail is frequently owing to a scrofulous diathesis, and it is accompanied with swelling of the extremity of the toe. In these cases, the most efficacious treatment is to cauterise the part with acid nitrate of mercury, or with the actual cautery. But when the primary cause of these disorders is owing to a syphilitic taint (which it is often difficult to distinguish from a mere inspection of the part), cauterisation produces no favourable result. However, we should not lose sight of other constitutional symptoms to help us in elucidating the diagnosis, such as pustules, exostoses, &c.; or, as in the case just cited, the coincidence of a rebellious blenorhagia. The difficulty of the diagnosis is increased if the patient presents all the attributes of a scrofulous temperament without having any symptoms of constitutional syphilis; then the want of success in our remedies, the commemorative history, &c., can alone guide the choice of treatment.

CASE.—*Ulceration of a Scrofulous Appearance in the Wrist Joint; Pustules on the Skin; Coppery Spots; Antivenereals; Recovery.*

The subject in this case had scrofulous ulcers of a doubtful aspect, which surrounded the articulation of the wrist; the parts were swollen, and motion impossible. The patient was of a lymphatic temperament. Several small pustules, and spots of a copperish colour, which were spread all over the body, induced me to look on the affection as caused by a venereal taint. The patient was put under the influence of mercury; he afterwards took the preparations of gold, attention being paid to the scrofulous disposition of his constitution. He left the hospital perfectly cured.

CASE.—*Scrofulous Constitution; Ulcer on the Left Arm; Nightly Osteocopic Pain; Antivenereals; Recovery.*

In the month of November, 1843, a young man came into the hospital to be treated for a swelling of the left arm, which was accompanied by nocturnal pain. He was of a decidedly scrofulous constitution. The diseased part was double its natural size, and a profuse suppuration flowed by a fistulous opening from about the attachment of the deltoid muscle. An antiscrofulous treatment had been already tried, without producing any beneficial result. From the history which the patient gave me of his having contracted chancres two years before, and of their disappearance by the use of mercurial ointment, I viewed the case as syphilitic, and prescribed the pills of Sedillot and sudorifics, to which were added afterwards some baths of the deuto-chloruret of mercury, and the preparations of gold. The extremity soon acquired its natural size, its functions were restored, and at the same time the pains disappeared.

POISONING BY ARSENIC.—Mr. Allison narrates, in the *Provincial Medical Journal*, a case of poisoning by arsenic, in which the recovery of the patient is attributable to free vomiting, and the use of the hydrated tritoxide of iron.

PLACENTA PRÆVIA.—Dr. Walker attended a case placenta prævia, complicated with great hemorrhage, in treating which he had recourse to the plan recommended by Dr. Radford and Dr. Simpson, and completely detached the placenta, which was immediately expelled into the vagina. The hemorrhage ceased at once, and did not return. The woman was afterwards delivered, by the operation of version, of a dead child. The mother recovered.

THE STRUCTURE AND FUNCTIONS OF THE BRAIN, WITH NEW VIEWS ON THE NATURE, CAUSES, AND TREATMENT OF MENTAL DISEASES.

By M. PINEL, M.D., Member of the Academy of Medicine, formerly Physician to the Bicêtre and Salpetrière Asylums; Author of the "Traité Medico-Philosophique sur l'Aliénation Mentale," "Medicine Clinique," "Nosographie Philosophique," &c. &c. Translated, with Notes, illustrative of some important doctrines in Physiology, Phrenology, and Moral Education,

By Dr. COSTELLO, Principal of Wyke House Asylum, Editor of the Cyclopedia of Practical Surgery, &c.

LESIONS OF THE INTELLECT IN THE STATE OF MORE OR LESS COMPLETE ABOLITION—IDIOCY, IMBECILITY.

There are, in the Saltpêtrière and Bicêtre, sections exclusively set apart for the imbecile and the idiotic. Having had the opportunity of observing them for many years, it struck me that something better might be worked out of these imperfect fragments of intellect than the statue of Condillac, and that we might realise by living facts what that illustrious thinker had only imagined in theory. The elementary nature of this work precludes me from entering on the physiological developments of which such a subject is capable; but I am nevertheless of opinion, that by carefully analysing the symptoms of idiocy, we may admit three distinct varieties of it, which are, brutishness, stupidity, and foolishness, each characterised by peculiar symptoms. As regards imbecility, it differs from idiocy, in the latter being congenital, while the former is the effect in persons whose intellect had been developed, of an intellectual degradation that has supervened gradually.

Brutishness.—I range in the last stage of intellectual debasement those beings more than idiotic, who are reduced to the condition of mere animated machines; all the senses are dead, not even excepting that of the physical wants, hunger and thirst; they would die for want of food, if food were not supplied them; they remain in the same spot and the same position in which they are placed; their existence is limited to digesting and breathing; intellect, instinct, propensity, all is dead within them. There was a little girl, of eleven years old, in the Salpêtrière, deaf, dumb, and blind; she was taken all but dead from her mother's side, who had expired several days before; she presented the true type of brutishness; she had less instinct than an oyster, for an oyster provides itself with food. We regard this condition of brutishness, *amentia*, as the last degree of idiocy.

Stupidity.—In a somewhat more elevated class we find those idiots who present some fragments of intellect; they at least are conscious of their wants, uttering cries when hungry, and going in quest of food; they often keep up an incessant motion, passing days, nay, sometimes years, in swaying their bodies automatically; grouped together almost continually, it would seem as if they felt the necessity of keeping each other company; and frequently, too, this clinging to each other seems to have no other object than to facilitate their propensity to masturbation. Some traces, too, of perception may be observed in them, but memory, attention, language, will, and conscience, are totally wanting: these are the stupid idiots. We find in them some imperfect traces of that conservative instinct which impels all living creatures, first to nourish themselves and then to reproduce their species; no sooner do we discover any obscure traces of perception in them, than we find an instinct brutishly to direct both these functions. This is stupidity, the second degree of idiocy.

Foolishness.—In a third degree may be classed those idiots who are capable of some education, intelligence, and propensities. They know the persons and objects by whom they are surrounded; they understand what relates to their wants; they go for and fetch what is pointed out to them, and make use of it; they are capable of being employed in cleaning, gardening, &c.; they can pronounce some words, or even portions of sentences. They often exhibit some of the bad propensities strongly developed; some show great adroitness in stealing from patients far above them in the scale of intellect; others give way to furious fits of passion; some show sense enough to conceal themselves when they do wrong, and some are capable of attachment and affection. There is a little idiotic girl in the hospital, who makes herself understood by gestures, cries, and ill-articulated words, and who has formed such a friendship for one of the female attendants, that she will not quit her for an instant. Some of them, too, are capable of education, an example of which I may mention out of a thousand with which I am familiar. A young girl, affected from her birth with hydrocephalus, and retaining an enormous enlargement of the cranium, was brought to the Salpetrière at the age of sixteen, in a state of complete brutishness, with a stupid look, dull eyes, and the limbs no larger than those of a child of six years. She was as incapable of understanding as of acting. After some months of care and perseverance, an attendant who had conceived a liking for her, succeeded in teaching her to hold the knitting needles, and subsequently to knit, and at last to articulate words and sentences. At the end of a year she could chat on various subjects, and at last acquired a certain degree of cunning playfulness. When asked how she was? her answer was "ver well." If she was ill? her answer was always "yes," and, putting her hand to her side, pretended to be in pain, in the hope of getting a little syrup, and in this she was often successful. Ideas, then, were combined in this imperfect head, a circumstance the more remarkable as, at the time of her admission, she was a mere brute machine, apparently destitute of any sensation. In her knitting she never could learn where to stop; her hands were a mere frame-knitter. For numbers her incapacity was the same; she could not count from one to two, nor distinguish them from each other.

In this class of idiots, perception, memory, and judgment exist, but in very feeble degrees; attention is almost impossible, the articulation of sounds is very difficult, and they have no consciousness of their state; the propensities, too, are exhibited the more openly, from the absence of intellect to control or correct them. I regard the possibility of speaking as the distinctive trait of this class, and as placing a great distance between it and the two preceding ones. Some birds also have this faculty, those especially in which the cerebral lobes are most developed; they can pronounce words, phrases, and even sing entire airs. The parrot speaks only by imitation; but by dint of repeating the name of a person, he at last utters the name when he sees the person, and then the parrot gives proof of perception, memory, judgment, and the expression of all these operations by the articulate word: it is also by imitation that the infant first learns.

Quadrupeds have not the faculty of articulate sounds, but in them the whole superior region of the brain is also much depressed. The animals, such as the bear, in which the depression of the skull is almost horizontal, can scarcely utter cries. The carib uses but a few short words, and the same is true of savages, who can never have a wider range of words than that of their wants; it would be vain to attempt to form from them a people with institutions; before this could be done, we should begin by crossing their race with individuals of a superior class. Among men of information, the talent of language always denotes an organisation above the common. Eloquence is the power of a high organisation, and hence its rarity and its influence.

We leave the class of idiots, being stupid from birth, to turn to another in which the loss of intellect is the consequence of disease—the imbecile. Certain physical alterations already noticed, and of which we shall have to speak again, have been the cause of their intellectual deposition; they may have enjoyed their faculties in their plenitude, of which they retain but the vestiges; this is the distinctive characteristic of the class. They hear, see, and feel, but their intelligence is but momentary; the memory ceases with the impression that produced it; their attention, to be sustained even for a little, requires to be stimulated every moment; the judgment seems to be correct, but its performance is null or contrary. We may regard it as intellect, but blunted, inert, inactive, unconscious. They speak unwillingly, work little, live peaceably, may make themselves useful, have not such strongly developed vicious propensities as idiots; they may entertain feelings of friendship, jealousy, shame; they appreciate certain sensations, have memory, can judge of the common acts of life, work at rough labour that does not require any nice discernment; their whole language is reduced to a few formulæ, or expressions that scarcely have any further range than what concerns their daily wants.

In the idiotic and imbecile, the intellectual organ is not only malformed, but this state of imperfection extends usually over the entire economy; they are diminutive, badly developed, and die young; others are ricketty, scrofulous, paralytic or epileptic. In such beings the lesions of the brain must therefore be deep, and, as we shall see, of easy appreciation. They are almost all affected with an alteration of the brain, a kind of hardening of the white substance. We shall relate a few cases of this kind, before entering on its general history.

Case 1.—Beler, a girl, ætat. 18, an idiot from her birth, was admitted into the hospital in June, 1821; her left arm and leg were paralysed, the hand was useless, being strongly bent on the forearm, which could not be extended; she walked with difficulty, dragging the left leg. Her intellectual faculties were very limited; she could only comprehend questions concerning her health, and it was only with difficulty she could pronounce *yes* or *no*, her only answers. She evinced no propensity; she was usually calm and quiet, but required constant care in regard to her natural wants. She had epileptic fits at intervals of about twenty-five days, succeeding each other, with short intermission, for thirty or forty hours. On 4th December, 1821, these fits returned, and were almost continual, succeeding each other for the space of four days with inconceivable rapidity; in the midst of the convulsions, the limbs of the right side were moved with violent shocks and contortions from within outwards. Those of the left side, which had been paralysed for a long time, exhibited strong shocks also; the general sensibility was annihilated. Face flushed, eyes squinting, evacuations involuntary, pulse frequent and irregular, breathing unequal and hurried. The patient died on the 4th day without any remission of the symptoms.

Autopsy.—Marasm; remarkable wasting of the paralytic limbs; skull thick, eburnated, hard to break; meninges white and healthy; the right lobe of the brain much smaller than the left, the convolutions of which are atrophied, squeezed together, and very small, especially in the frontal and occipital regions, while they are large and deep in the superior. The cortical substance seems more abundant, and its layers thicker than usual; the lateral ventricle very small and dry. The substance of the brain throughout the right lobe, that is, beneath the ventricle, is remarkably hard, and tears with difficulty in the fingers into long bands converging towards the corpus striatum.

The texture of the left lobe is healthy, and presents a striking contrast to the organic alteration of the right one; there is a strong injection in the spinal arachnoid. The substance of the spinal marrow, which is of the natural consistence in the cervical region, is softened and diffluent opposite to the eighth and ninth vertebræ; this softened portion is separated above and below from the healthy parts by a reddish line; the rest is sound. Nothing remarkable in the viscera. The sciatic nerve of the left limb, which had been paralysed and contracted a long time, and which I had expected to find atrophied, was redder and larger than that of the right thigh, in which motion was performed till the time of her death.

If we apply pathological analysis to this case, we shall see the necessity of distinguishing, amongst the different lesions found in the dead body, those which are to be considered as the cause of the long-standing paralysis and idiocy from the recent alteration of the spinal marrow, the accidental cause of death.

1. The induration and atrophy of an entire cerebral lobe can scarcely be imagined as giving rise to consequences less serious than the loss of movement in one side of the body, the almost complete annihilation of the intellectual faculties, and the epilepsy in all probability. This alteration, which is a frequent one in idiots, but of which it is often difficult to perceive all the various shades, shews itself usually less by the paralysis of the limbs than by the distortions it produces in the

feet and hands. In regard to the augmentation observed in the size of the sciatic nerve of the paralysed limb, Reimarus appears to have remarked this condition in certain alterations of the nerves.

2. The partial softening of the spinal marrow is a much more rare disease. This is only the third instance in which I have met with it. M. Magendie published the two first in his journal (January, 1821). In the present case, the symptoms present a complication not observed in the former, viz., the convulsive shocks in the limbs; while in the former cases they were confined to the trunk only, and did not extend to the arms or legs. This symptom is chiefly referable to the induration of the brain, of which convulsions so often usher in the fatal termination. I persist in regarding the convulsive shocks that affect the trunk solely, as one of the characteristic symptoms of inflammation of the spinal marrow. It must also be borne in mind that this patient was epileptic, and that the profound lesion of the brain was, in all probability, not disconnected with the origin of the nervous affection; and let us bear in mind, also, that epilepsy affects fatally both the sensibility and muscular motion, that the spinal marrow is the principal organ of the movements, that the principle of sensibility resides in a portion of this organ, and that the spinal marrow, before it became so rapidly inflamed, must have been for a long time the seat of a chronic inflammation, on which the epilepsy may have in a great degree depended.

Case 12.—A woman, named Borna, ætat. 52, had experienced within the last three years several attacks of paralysis, which had reduced her to a state of complete demency. During the year she had been in the Salpêtrière her symptoms were, a flushed face, natural corpulency, difficulty in walking, standing, or talking; the intellectual faculties almost gone, she could scarcely think of asking even for food; she was quiet, and her appetite voracious. On the 21st of January, 1821, she had a fresh attack of paralysis, taking away all power of speech and motion; paralysis of the right arm, and contraction of the right leg; her answers were tears and cries.

March 7.—Face flushed; eyes brilliant; the right side without motion; sensibility also very obscure, as no sign of pain is produced by pinching or deep pricking; but any attempt to move the right arm or leg excites her to utter piercing and painful cries; pulse frequent and irregular; breathing nearly natural; evacuations involuntary.

10.—Countenance ghastly; eyes fixed, and turned upwards; there are some slight convulsions of the right limbs; the insensibility seems general. Death during the night.

Autopsy.—Cranium thin and very fragile; cerebral convolutions large and deep. On attentively examining the right lobe, cutting it in thin slices, three small cavities were discovered just over the ventricle, the largest situated anteriorly, and only a line and a half in diameter, contained a reddish fluid, and was lined with a citron-coloured resisting membrane. The rest of the substance of this lobe was remarkably firm—almost indurated. In the corresponding point of the left lobe two similar small cavities were observed. In the upper middle portion of the left ventricle there was a considerable induration of the medullary substance, resembling white of egg, boiled hard; very resisting, and containing a cavity four lines in diameter and depth, and filled with serum, lined with a similar yellow membrane, and divided by membranous bands in every direction. The indurated portion was as large as a walnut. Beneath the ventricle there was a similar cavity. The indurated portion was continuous with the rest of the cerebral pulp, which was throughout hardened in the same manner as the right lobe.

The cerebellum shrunk and wrinkled presented a fibro-cartilaginous induration throughout its posterior edge, resembling whitish hide. I shall speak of this alteration hereafter. There was a sanguineous affection of about the volume of a nut in the left lobe, containing blood, and a few granulations. The membrane lining this small cavity was of a reddish hue, and seemed organised (the patient had an attack of paralysis about forty days before). The spinal prolongation was bulky, and of remarkable hardness and consistence, especially in the interior, where the grey substance was abundant. The other viscera healthy.

Reflections.—This patient having only been in the Salpêtrière one year, it is scarcely possible to fix the precise period of the commencement of the disease. The details show that, up to her forty-ninth year, she had been lively and active; that during the three following years she had frequent attacks of paralysis, and that, at last, she lapsed into a state of tranquil demency. The small cavities found in the two lobes, and which were the only vestiges of sanguineous effusions, account readily for the frequent occurrence of the paralytic symptoms; but the general induration of the encephalon, the partial indurations of the brain, and the alteration of the cerebellum particularly, cannot with certainty be attributed to any known cause. Let us for a moment consider each of these alterations separately.

1. Five out of the seven small cavities found in the white substance were lined with yellowish membrane, filled with serum, and divided by membranous bands. One only of them appeared to have no lining membrane, and another resembled a cylindrical hole, and contained nothing. There can be no doubt of the hemorrhagic origin of the first five, particularly when we notice the same smallness, commencement of organisation, and appearances in the small cavity of the left lobe of the cerebellum. But this was not the case with the remaining two, and I cannot say whether they are to be considered as the results of long-standing effusions entirely absorbed, or as another kind of alteration hitherto unknown.

2. The general induration of the encephalon, and the two partial indurations of the brain, are not more easily explained; but we may remark, in reference to this lesion, that the two circumscribed indurations of the brain correspond with a cavity formed by sanguineous effusions; that in all probability this softened and altered the surrounding parts, and that the blood having been removed by absorption, this process may have changed the state of the softened parts into one more compact and hard.

3. The induration of the cerebellum is the more remarkable from the fewness of the well-established instances of such alteration. The hardened edge, when separated from the sound cerebral pulp, and placed on live coals, was quickly converted into a substance like horn, while the sound matter from the same cerebellum dilated under the action of the fire, producing a nauseous smell. A portion of the diseased tissue, subjected to roasting on a hot iron, was changed into a brownish resisting mass of varnished appearance, while the healthy pulp was converted into a dark, light substance, resembling lampblack. This difference in results shows plainly a great difference of organisation, and assimilates the morbid substance with fibrous tissue. It is also important to remark the severe pain the patient complained of whenever her limbs were moved, contrasting with their profound insensibility to the action of the most powerful external irritants. This symptom almost always indicates that a deep organic alteration is going on slowly in the nervous centres; and hence have I observed it in several cases of cancer and induration of the brain.

Case 3.—Louise Dumont, ætat. 31; her life was almost automatic; has lived in a state bordering on stupidity since her infancy; she was incapable of either precaution or care; all her wants had to be attended to; she spent almost the whole day in a corner of the dormitory, rolled up, and on the ground, uttering only sounds without meaning, incapable of replying to or comprehending even the simplest question. The left arm and leg were paralysed. Circulation, respiration, and digestion were natural. She seemed wild, and concealed her visage on her breast when any one looked at her. She died during the night on the 7th of March, 1820, without exhibiting any symptom of organic disease.

Autopsy.—Countenance livid, head large in proportion to the rest of the body; vertebral column strongly deviated to the right. Cranium thick, eburnated; dura mater thin and transparent; arachnoid healthy. Right lobe of the brain much larger than the left, presents under the ventricle a well marked induration of the medullary substance, and confined to the space of the ventricle. Instead of yielding under the fingers, as in the healthy state, the altered brain can be torn in longitudinal fibres. The other lobe seems healthy. Cerebellum soft on its under surface; spinal marrow firm, bathed in the lumbar region by a little serum. Lungs healthy; walls of the left ventricle of the heart thickened to such an extent as almost to obliterate the cavity; it scarcely admitted the end of the little finger. This hypertrophy of the heart was general. The rest of the viscera healthy.

Reflections.—After the induration and the atrophy of the left lobe of the brain, the most remarkable alteration in the case was the great hypertrophy of the left ventricle of the heart. This disease often terminates during cold weather by sudden syncope, and the night of her death was cold. We might be surprised that so grave an alteration had given rise to no apparent symptom during life, did we not know that amongst the insane, and the idiotic more especially, the accidental maladies are almost always latent, and we may add that, amongst the idiotic affected with induration of the brain, there is superadded the physical impossibility of having the perception of pain.

Case 4.—Marie Grichois, an idiot from her birth, of robust constitution; the catamenia appeared for the first time at the age of 17. Having lost her parents, she was admitted into the Saltpetrière 1st Pluviose, anno v.; her age at the time was 27. Her appearance was squalid and disgusting, and she often gave way to fits of passion and impatience; if nothing were given her to do, she remained idle, but she readily performed the most fatiguing labour; she even seemed capable of some attachment. Intellect limited, memory null, answers slow, and seldom correct; she could comprehend only such questions as related to her wants. Although there was no appearance of paralysis in the arms, the lower limbs, particularly the right leg, seemed to drag. The digestion and circulation possessed remarkable energy. She had an attack of measles at the age of 47; on the second night of the eruption she got out of bed, and wandered almost naked through the dormitory. Next day the eruption changed from red to violet, and then to a blackish hue, and faded away altogether. On the fourth day she had all the symptoms of typhus; complete abolition of sensibility; breathing short and difficult; pulse small, frequent, irregular; cold, clammy sweat; general prostration; tongue and lips covered with black sordes; death during the night.

Autopsy.—Head and skull small in comparison with the rest of the body; anterior and lateral parts of the head much depressed; skull thick, its capillaries injected; cerebral sinuses gorged with blood; dura mater thickened in the parietal depressions, and strongly adherent to the skull. Down to the ventricles the brain presented no sensible alteration; but just beneath them, the rest of the brain, and the left lobe more particularly, presented a remarkable degree of density and hardness. This part appeared to be destitute of capillaries, while in the upper brain they were very numerous and highly injected. Cerebellum appeared healthy; spinal marrow presented the same hardness, particularly throughout the length of its posterior surface; thoracic viscera healthy; liver large; the intestinal canal, from the middle of the œsophagus downwards, was deeply inflamed; its mucous membrane red, bloody, dotted with brown circumscribed spots. The other viscera healthy.

Reflections.—In this, as in the preceding case, we find two distinct alterations; the one accidental, followed by a fatal termination; the other anterior, the cause of the idiocy and of the paralytic symptoms. Both deserve to be inquired into.

1. While labouring under an acute cutaneous eruption, the patient exposed herself to cold; next day the eruption disappeared, and metastasis suddenly took place to the mucous membrane of the intestines. We were prepared by the brown sordes on the lips and tongue, the cold clammy sweat, and the general prostration, to expect high inflammation of the membrane. This close sympathy between the skin and mucous membranes, the analogy of their structure and functions, must predispose them to the same disease; and hence Bretonneau has shown that the alimentary canal, like the skin, may become the seat of variolous eruptions, and that

most of the putrid and typhoid fevers are owing to similar affections.

2. The induration of the encephalon, in this case, possesses a peculiar character, particularly remarkable in the left lobe of the brain, and extending also to the posterior part of the spinal marrow. This last lesion must have deeply affected the movements and sensibility of the limbs; and, accordingly, we find in this woman, besides the evident paralysis of the right leg, a general sluggishness and inertness of the movements, and a complete insensibility of the skin covering the limbs.

REPORTS ON DISEASES OF FEMALES.

By EDWARD RIGBY, M.D.

Fellow of the Royal College of Physicians, Senior Physician to the General Lying-in Hospital, Lecturer on Midwifery at St. Bartholomew's Hospital, Examiner on Midwifery to the University of London, &c.

In illustrating with cases the observations which I lately made on prolapsus uteri, I must premise the confession that I have taken notes of very few; the displacement is so common, and its symptoms and treatment are generally so simple, that a description and history of every case would have soon become little more than an useless repetition.

S. P., ætat. 51; married; no children.

Sept. 9, 1836.—Complains of much pain and dragging about the loins and groin, increased by exertion in the upright posture, and becoming worse towards night; occasional difficulty in passing water, which is high coloured, and, when it does flow, the direction of the stream is more horizontally forwards than usual; no appetite; much gastric derangement; bowels confined; no leucorrhœa.

Ceased to menstruate three years ago; was formerly much subject to leucorrhœa.

Exam. per Vaginam.—Os externum very tender; uterus is large, and has descended quite to the perinæum; os uteri painful.

R. Pil. hydrarg., Extr. coloc. co. āā gr. v, o. n.

R. Magnes. sulph. ℥ss, Magnes. carb. gr. xv, o. m., ex aqua menth. pip.

R. Quinæ disulph. gr. ij, bis die.

R. Lotio plumbi.

16.—Better. Pergat.

23.—The symptoms of prolapsus have almost, if not entirely, disappeared, but she complains of much heat at the os externum, and has a bad taste (sour and bitter) in the mouth. Urine of a better colour than before, and flows more naturally.

Rep. pilulæ et lotio.

R. Acidi nitrici dil. m. xv, ex Infus. gentianæ co. ter die.

R. Pulv. jalapæ co. ℈j, o. m., sumat Sodæ sesquicarb. gr. x, o. nocte ex aqua cum pilulis.

30.—Improves; less heat of vagina. Pergat.

October 14.—Better in every respect. Pergat.

28.—Better. Pergat.

It is difficult to say how long this state of partial prolapsus had continued; but from the fact of her having been long subject to leucorrhœa, it is probable that the displacement was also of some standing.

As she had never had a child, the perinæum formed a sufficient support to prevent the uterus from descending lower. The catamenia also having ceased, and the mucous membrane of the vagina becoming much less freely supplied with blood than before, not only had the leucorrhœa disappeared, but the pressure of the os uteri upon the perinæum had begun to produce a good deal of irritation near the os externum; the more so as the uterus had swollen considerably from the obstructed state of its circulation. The altered direction of the stream of urine, from the urine having been dragged more or less downwards, is also worthy of notice.

The treatment was simple enough. The bowels were well cleared of their contents, so as to remove, as far as possible, all pressure from the uterus, and tonic medicines given. The only local application was Goulard's lotion, to allay the irritability of the vagina and os externum, and as her health improved the prolapsus gradually disappeared.

M. C., ætat. 30; married three years; had an abortion soon after marriage.

August 7, 1842.—Has a white creamy discharge, with dragging pain of back, and other symptoms of prolapsus. The os uteri is felt just within the os externum; but there is neither much local pain nor general derangement of health; bowels rather confined.

R. Pil. hydrarg., Extr. hyoscyam, āā gr. v, o. n.

R. Aquæ menthæ viridis, Aquæ distill. āā ℥vss, Acidi sulphurici dil. m. x, Syrupi rhœados ℥ss, Magnes. sulph. ℥i. M. ft. haust. o. m. s.

R. Acidi nitrici dil. m. xv, ex Infus. gentianæ co. ter die.

Lotio plumbi.

13.—General health much improved; prolapsus has diminished.

R. Pil. hydrarg., Extr. coloc. co. āā gr. v, alternis noctibus sumend.

R. Pulv. rhæi gr. x, Confect. aromat. ʒss, Aquæ cinnam. ℥iss. M. ft. haustus o. m. s.

R. Decoct. quercus c. alumin. Rep. haust. gentianæ.

20.—Much better; has had no symptom of prolapsus since last report. Rep. omnia.

It is always desirable to commence the treatment of prolapsus with a gentle purge; for, by unloading the bowels in the first instance, it is sometimes astonishing what progress we can make in the cure of the displacement by this simple means. Saline purgatives are usually the best to begin with, for they not only thoroughly clear the bowels, especially if preceded by a mercurial, but, by producing watery evacuations, they seem to relieve the congested state of the uterine vessels, and diminish the size and weight of the prolapsed organ itself. Having persisted in their use for a few days, it will then be desirable to adopt the purgatives which I prescribed on the 13th, and which, by promoting the peristaltic action of the intestines, would prevent accumulation and consequent distention, and counteract that disposition to abdominal swelling which usually exists in these cases.

In most cases it is better not to commence with an astringent injection. There is usually more or less irritation present, and we shall proceed much more safely by using the common lotio plumbi in the proportion of ʒij of the liquor plumbi diacet. to ℥viij of distilled water. In some cases of partial prolapsus this will be sufficient; if not, we can then have recourse to astringent injections.

A. W., ætat. 58; mother of six children.

April 23, 1835.—Complete prolapsus uteri of seven years' standing; bowels much confined.

R. Haustus sennæ o. m.

R. Decoct. quercus c. alumine.

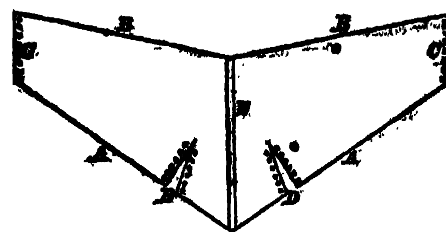
Let her lie down, and push up the uterus into its natural position. Let her pass a cylindrical piece of sponge into the vagina, previously soaking it with the lotion, and then apply a broad T bandage to support it.

28.—Feels much better; the uterus not descended, except when she has exerted herself. Pergat.

May 26.—Is much improved in health; feels more comfortable, and is more active. Uterus came down only once last week. Pergat.

June 23.—Feels well; removed the sponge a few days ago, but was obliged to have recourse to it as the uterus began to descend. Pergat.

July 14.—Rep. mist. sennæ.



R. Decoct. quercus lb. j, Tinct. catechu ℥ss, Alumina ʒij, Zinci sulph. ʒi. M. ft. lotio.

Nov. 17.—Uterus has come down but two or three times since last report. Rep. lotio.

R. Pil. aloes, c. gr. v, o. n.

At the time this case was taken, I did not sufficiently appreciate the value of a bandage to support the abdomen, and thus prevent the weight of its contents from passing upon the uterus, and have no doubt that the disposition to relapse would have been greatly diminished in the present case if this simple means had been employed.

It is generally supposed that a properly adapted bandage, or belt, to support the abdomen in cases of prolapsus, or advanced pregnancy, is a comfort which is unattainable by a poor person on account of the expense; but so far from recommending any of the elaborate pieces of workmanship which are made for that purpose, I have generally found that, independently of their costliness, they were not only uncomfortable from their thickness and consequent warmth, but failed in the main object of supporting the abdomen. I have for many years been in the habit of recommending to my patients a belt which they can make themselves with the greatest ease, and the cost of which is so trifling as to be within the means of the poorest hospital patient. The annexed diagram gives a representation of it; the material is either linen or calico, and therefore may be worn at all seasons without inconvenience.

AA. The lower edge sloped so as to fit closely into the hollow of each groin.

BB. The upper edge.

CC. The ends of the belt furnished with eyelet holes for the purpose of lacing behind.

DD. Wedge shape portions cut out for the purpose of contracting the lower margin, and thus making it sit closer into the hollow of the groin.

E. A thin strip of whalebone running down the centre, so as to keep it quite smooth, and prevent the lower edge from sucking.

A. H., ætat. 50; mother of eleven children.

April 28, 1835.—Complete prolapsus uteri of a year's duration; much leucorrhœa.

R. Liq. plumbi diacet., Tinct. opii. āā ʒij, Aquæ distillatæ Oj. M. ft. lotio. Haust. sennæ o. m.

May 12.—Uterus has only come down once since last report, but there is much leucorrhœa and a slight discharge of blood.

R. Pil. hydrarg., Extr. gentianæ āā gr. v, o. n.

Rep. Haust. sennæ.

R. Decoct. quercus c. alumine.

19.—Uterus has not come down once since last report; the leucorrhœa continues, but there has been no blood. Has had a good deal of heaviness and pain of head, and was very feverish two days ago, since which a leprous eruption, which itches and burns exceedingly, has come out; it is most upon the right arm; mouth slightly sore; gums swollen. Omitt. Pil. and decoct. quercus c. alumine.

R. Magnes. sulph. ℥ss., Magnes. carb. gr. xv, ex Aq. menth. pip. o. m.

R. Ung. hydrarg. ammonio-chloridi.

21.—Feels better; uterus has not prolapsed; eruption much less irritating.

Rep. Lotio. plumbi. et haustus magnes. sulph.

R. Decoct. sarzæ., Liq. calcis āā ℥j. quater in die.

June 21.—Uterus has not prolapsed; eruption has almost entirely disappeared.

Rep. Decoct. sarzæ c. liq. calcis. et haust. magnes. sulph.

Rep. Decoct. quercus c. alumine.

Aug. 21.—Itching and eruption have disappeared; the uterus has prolapsed. Let her use a sponge tied into a cylindrical form, and soaked in the lotion. Pergat.

Sept. 4.—Feels stronger; no prolapsus; has still some leucorrhœa. Pergat.

The feverish attack and eruption which appeared during the early part of this report was, I presume, an effect of the astringent lotion suddenly checking a discharge to which the system had become accustomed, without substituting an adequate evacuation by some other outlet. I trusted that sufficient precautions on this head had been taken, by ordering the mistura sennæ and lotio plumbi., but the result proved that I should have done better if I had used a saline laxative, which, in all probability, would have prevented the astringent lotion disagreeing with her.

J. P., ætat. 31; mother of three children.

Feb. 9, 1836.—Complete prolapsus uteri since last confinement, eighteen months ago. Much leucorrhœal discharge, occasionally mixed with blood. The uterus is so prolapsed that it prevents her sitting down. Is unable to retain her water long, and suffers much pain when the bowels are moved, or when she coughs. The uterus is so swollen that

she is obliged to lie upon her back for two hours before she can return it. Bowels much relaxed.

R. Pil. hydrarg. Pulv. ipecac. co. āā gr. v, o. n.

R. Acid. nitrici. dil. *m.* xv, ex Infus. gentianæ co., t. d.

R. Lotio plumbi.

March 1.—Ten leeches were applied to the uterus on the 23rd, and bled freely; is better; the uterus only comes down when she walks about.

R. Pulv. rhæi formâ pilulæ, gr. v, o. n. Rep. Haust. and lotio. Let her use a sponge.

8.—Uterus has kept up by means of the sponge; much cough. Rep. Pilulæ.

R. Decoct. quercus c. alumine.

R. Vini. ipecac., *m.* xv, ex Mist. ol. amygdal. t. d.

22.—Has caught cold, and did not come to the hospital last week, when the uterus again prolapsed. Pergat.

29.—Much better; cough still troublesome; leucorrhœa diminished; uterus has not come down. Rep. Pil. and lotio.

R. Tinct. scillæ, *m.* xv., ex Mist. ol. amygdal. t. d.

April 12.—Bowels much relaxed; has been exposed to much fatigue since last report, and the uterus has come down once. Rep. Mist. ol. amygd.

R. Mist. cretæ p. r. n.

R. Argenti nitr., gr. v, Aquæ distill., ℥ j, solve ft. lotio.

19.—Uterus has not prolapsed; cough still severe. Pergat.

May 3.—Has been obliged to work hard, and the uterus is again completely prolapsed. Pergat.

The original cause of the prolapsus in this case was probably her having risen too soon after her last confinement, and being very poor, and obliged to work very hard, the displacement soon became of an aggravated kind. The discharges of blood which occasionally accompany a complete prolapsus, quickly disappear when the uterus is returned to its natural situation, and the patient preserves the horizontal posture. In the early part of the case there seemed to be every promise of a successful termination; but her extreme poverty compelling her to work hard, when unfit for any exertion, and requiring rest, gave her little chance of permanent amendment.

ON STRICTURE OF THE URETHRA, AND ITS TREATMENT.

By LEROY D'ETIOLLES, M.D., Member of the Academies of Brussels, Madrid, St. Petersburgh, &c.; of the Imperial Society of Physicians at Vienna; of the Royal Medical Society of Edinburgh; of the Medico-Chirurgical Society of Berlin; of the Society of Medical Sciences at Lisbon; of the Royal Society of Arts and Sciences at Nancy; of the Medical Societies of Antwerp, Bruges, Ghent, Guadalaxara, Lyons, Malines, Munich, Nancy, Willebrock, and Paris; and of the Council of Health at Brussels.

Condensed from the original by JOHN FOOTE, Esq., M.R.C.S.L.; Honorary Secretary of the Royal Medico-Botanical Society; Corresponding Member of the Sociedade Pharmaceutica Lusitana; of the Société Industrielle at Angers, &c. &c.

(Illustrated by wood-engravings.)

NATURE OF STRICTURE.

Stricture of the urethra may be regarded as a permanent diminution of the size of the canal, resulting from a morbid condition of its parietes. The pathological nature of the changes which produce it, however, is still a matter of doubt, owing probably to the infrequency of death from stricture; when a fatal termination does occur, it is in a secondary manner, either from catarrh, nephritis, prostatitis, &c., and then the characters of the stricture disappear before the more important alterations which have caused the death of the patient. In the second place, the traces of a stricture are not always discoverable after death, even when it has been a very firm one, and has been repeatedly cauterised. As soon as the vital spark has left the body, its different parts are modified in their structure: the part of the urethra which previously would not allow a bougie, the thickness of a hair, to pass, will then give admission to bougies two or three millimetres thick. It is also very difficult to ascertain the existence of strictures by slitting up the canal in its length; it is better to cut it across above and below the part where the contraction exists, leaving that part altogether intact.

These difficulties have been the cause of the difference of opinion which at present exists with respect to these affections, of which several classifications have been given, among which the following may be cited:—

Desault admitted three kinds of stricture: one external to the canal, another in its parietes, and the third in its interior, on the surface of the mucous membrane. Sir Charles Bell only recognised two: the dilatable, and the non-dilatable; but the greater number of English surgeons divide strictures into three kinds: spasmodic, permanent, and mixed, the latter being the organic stricture complicated with spasm. M. Cruveilhier made only one distinction in strictures: one is superficial, and confined to the mucous membrane; the other deeply seated, and of a fibrous nature. Béclard established two divisions; in the one he placed inflammatory stricture, and in the other organic stricture, which he subdivided into bridles (or bands), callosities, sub-mucous indurations, ulcerations, carnosities or vegetations, and varices. This division, which is correct in some respects, is nevertheless faulty. Can it, for instance, be said in a case of inflammatory stricture, that there is not any organic alteration? This division will admit of modification relative to the character of the strictures, and especially to practical applications.

The following is the classification which I would propose, without, however, attaching more importance than they deserve to those species which are not always recognisable during life:—

Organic Strictures.—1, Inflammatory; 2, fungous; 3, valvular, comprising folds, valves, bridles or bands, and rugosities; 4, fibrous, corresponding to callosities; 5, turgescent and erectile; 6, ulcerated; 7, vegetating, corresponding to carnosities; 8, varicose; 9, cartilaginous.

The *inflammatory* strictures sometimes affect healthy urethræ, sometimes those that are already strictured; to this Messrs. Bégin and Lallemand have with great propriety drawn attention, as they differ very greatly in their consequences. It may be re-produced by violent gonorrhœa, the use of injections, the introduction of foreign bodies into the urethra (catheters, calculi, &c.), by blows, or other acts of violence. The swelling caused by the inflammation generally yields to the antiphlogistic treatment, but the resolution is sometimes not complete, and then there follows one of the varieties of stricture which has been enumerated above. *Fungous* strictures depend on a chronic vascular tumefaction of the mucous membrane. Nearly all strictures begin thus, and they only lose this character in the course of time, or by rash treatment.

It has been already said that *valvular* folds are occasionally met with in the urethra, particularly at the commencement of the prostatic portion, and at about an inch from the meatus urinarius, on the projection formed by the deep lip of the fossa navicularis. These natural folds are not the only ones which offer an obstacle to the course of the urine; others, in much greater number, the products of a pathological alteration, are formed, sometimes by a mere puckering of the mucous membrane, at others by the cicatrix of a superficial ulceration. These, like the greater number of strictures, are met with at the commencement of the membranous portion. These bridles are thin at first, and formed merely by the adhesion of two thicknesses of the mucous membrane, but after a time the base is enlarged by a gradual effusion of coagulable lymph and the thickening of the sub-mucous tissue, but the centre or free edge generally remains thin, as may be seen by the impression made on the wax bougie, which resembles that caused by a thread ligature. The base or fixed point of these valvular folds is not always on the same paries of the urethra. At the meatus urinarius they generally spring from the inferior angle, on the side of the frænum, and they resemble the hymen; that which sometimes exists on the deep lip of the fossa navicularis, about an inch in the canal, adheres most frequently to the upper paries; at the commencement of the prostatic portion, on the contrary, the free edge is found above. The valvular folds at the orifice of the membranous portion are sometimes above and sometimes below, according to the cause which produced them. During the spasmodic contraction of the muscles which take place at this part, there is sometimes formed a transverse fold on the upper part, and the repeated resistance this offers to the passage of the urine, together with the consequent irritation, change it into a valvular stricture. Congenital valves of the same part also adhere to the upper surface, but the bands and cicatrices to which gonorrhœa gives rise are generally seated on the lower paries of the urethra. These bands have a great tendency to pass into the fibrous state.

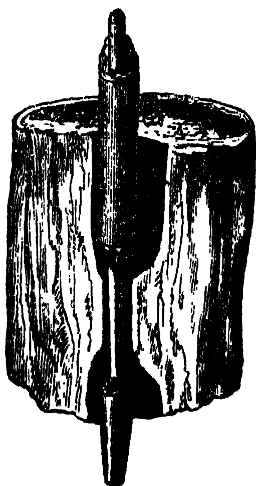
Fibrous or *callous* strictures are formed by thickening, deep cicatrices of the mucous membrane, and by engorgement of the sub-mucous tissue, the result of this simultaneous alteration being an inodular substance which becomes dry, loses its sensibility, assumes a pearly aspect like that of tendons, from which it differs in the very close interlacing of its fibres. When a catheter is passed through such a stricture, the hardness of the tissue, and the force with which the instrument seems to adhere to it, is remarkable.

The attentive examination which has been made of cicatrices of the skin and the external tissues, may by analogy afford a satisfactory explanation of the phenomena which occur in the inodular tissues of the urethra. The diminution of the vascularity of this tissue, demonstrated by the injections made by John Hunter, the want of porosity, the almost complete absence of exhalent and absorbent vessels, pointed out by several authors, and especially by Dupuytren, explain the dryness of the surfaces. The retractile power which cicatrices possess is, as Delpech said, exercised in a slow but constant manner, and can only be stopped by a mechanical resistance as powerful as itself: this concentric retraction explains the alway-increasing diminution of the calibre of the urethra, and the almost immediate reproduction of the stricture, as soon as the surgeon ceases to force through it by dilatation. In order to neutralise this retractile power of the inodular tissue, no more certain means has been found than the ablation of the external cicatrices. We shall see in what way it is possible to make the resection of fibrous strictures of the urethra, and what is the result.

M. Cruveilhier is of opinion that the fibrous stricture is not only the most frequent, but almost the only form of stricture. He says there is a complete disappearance of the mucous membrane at the situation of the stricture, and a more or less complete disappearance of the spongy erectile tissue of the urethra. He explains its origin either by chronic inflammation of the mucous membrane, or by the previous occurrence of ulceration, but he adds, there are too few pathological facts in relation to the state of the canal of the urethra in gonorrhœa to settle this question in a positive manner. He is, however, inclined to refer the formation of the stricture to ulceration, because it would be difficult to understand how the effects of inflammation could be almost constantly limited to a single point in the length of the canal. The therapeutic consequences of the fibrous nature of the stricture, according to M. Cruveilhier are, the inconvenience of the *cathetérisme forcé*, and of conical catheters, the pre-eminence of dilatation over cauterisation, the necessity of a long-continued dilatation, the tendency of the stricture to relapse, and the *absolute incurability of every stricture in the canal of the urethra*:—such are the therapeutic data obtained from the pathological anatomy of strictures.

There is, unfortunately, a great deal of truth in these remarks of Cruveilhier, as far as regards fibrous strictures; but, happily, they are not all of that nature, and the learned pathologist has himself divided strictures into two classes: the superficial, limited to the mucous membrane; and the deep-seated, in which the entire thickness of the canal of the urethra has undergone the fibrous transformation. The first class are readily curable, when the inflammation has not extended to the sub-mucous tissue, or destroyed the mucous membrane, in consequence of imprudent manipulations.

M. Cruveilhier has seen fibrous stricture affect two forms; in the one, in common with many other pathologists, he has found it spindle-shaped—that is to say, it resembled two cones with their bases lying back to back, the fibrous tissue occupying the entire thickness of the paries to the centre of the swelling, and then diminishing in thickness towards the extremities, where the alteration in structure is confined to the mucous membrane. In the second form, the fibrous tissue occupies one



point only of the urethra, so as to resemble a circular strangulation, similar to that which would be caused by a tightly drawn cord. Bands and valvular folds are here evidently spoken of; a large number of which, not being the result of a cicatrix, are not formed by inodular tissue. The spindle-shaped enlargement constituting a fibrous stricture, has also been noticed by M. Lallemand.

The *turgescent* strictures may be met with in every part of the urethra, inasmuch as the turgescence is the result of an afflux of blood in the vessels of the tissues which form the stricture, and of the tissues which enclose it; but they are more frequently found in the spongy portion, on account of the erectile nature of the tissue around the stricture, which swells much more than the mucous membrane can. This turgescence, this erethism, by which the bougies introduced into the urethra are more compressed after they have been in the canal half an hour than when they are first passed, and by which they are in some cases expelled from the urethra, has been mistaken for spasmodic action. These phenomena must be referred to the blood in the spongy tissue, when no appearance of fibrous tissue can be distinguished after death under the tumefied mucous membrane.

Whilst the mucous membrane remains undestroyed, and the inflammation has not passed beyond it, the stricture is curable; passing a sound for a few days will remove it, but if the low inflammation has extended to the sub-mucous cellular and to the spongy tissues, if the latter tissue be exposed by the destruction of the mucous membrane, if it has become hardened, and fibrous, then its cure is no longer probable; the stricture does not impart to the catheter or bougie the sensation of an elastic substance, but rather that of a hard and horny substance, as has been already remarked. This transformation of tissue increases rather than diminishes the constriction which strictures, when they have become fibrous, exercise on catheters and bougies, for the eccentric layers of the spongy tissue, which have not become fibrous, preserve their erectile property, and exert a very energetic degree of pressure on the fibrous circle, when a cause of irritation brings that property into play. Of this the following is a remarkable case:—

M. D——, of Batavia, 49 years of age, had had several attacks of gonorrhœa, the first when eighteen years old, and the last when five-and-twenty, for which he was treated at first by vinous, and afterwards by astringent injections. Mercurial frictions were also had recourse to in treating chancres at the base of the glans. Immediately after the last attack of gonorrhœa, the size of the urinary jet rapidly diminished, until the water was at last passed only by drops. A medical man at Java, Dr. Fritz, passed bougies, but without effecting a full dilatation. The next year, Dr. Vanderkhoven cauterised the urethra nine times at two points, behind the bulb, about two inches deep, from which much improvement was derived for about three years, after which he had again a difficulty in making water, without any appreciable cause for the relapse. The difficulty continued to increase slowly, and, in 1840, neither catheter nor bougie could be passed, the patient not being able to procure one at Java less than a line in diameter. This state continued for two years, and in 1842 M. D—— came to Europe. I found a fibrous ring at two inches depth; a bougie half a line diameter passed through, and I then met with a second stricture at five inches and a half—this offered less resistance. Temporary dilatation for an hour at a time was practised daily; bougies of two millimetres, two and a half, and three, being successively introduced. No further improvement taking place after the lapse of a fortnight, and the first stricture being rebellious, I kept a small catheter in for thirty hours, and then, when the ramollissement began, I made the dilatation *coup sur coup*, increasing the size of the instrument by a millimetre every eight hours.

The introduction of the first catheter was so far peculiar, that in order to traverse the neck, which was turned very much to the right, I was obliged to use a gum elastic catheter without a stylet, having a curvature as sudden and as short as that of the Eustachian tube catheter. I shall refer hereafter to these sounds and their use. The fourth day of the rapid permanent dilatation, the urethra could admit a catheter of three lines and three quarters diameter; the catheter was withdrawn. The next day, the seat of the first stricture had resumed the same condition as before the catheter remained in the canal. After a few days the dilatation was resumed, and carried on more rapidly than before; this time the catheters, of seven millimetres, were retained in the canal for three weeks. Two days after their removal, the first stricture was as narrow as before. Scarifications were then made on three occasions, followed by temporary dilatation, but with the same negative result. I then determined to have recourse to cauterisation, in order to excite a discutient action in the indurated tissue, in the hope that the nitrate of silver might thus repair the mischief it had made. In order to be sure that its action should be exerted on the diseased, and not on the healthy parts, I used the retrograde porte-caustique, a tube pierced near its extremity with two lateral openings, and terminated by a semi-olivary projection. This latter body, after having passed through the stricture, is arrested by it in returning, so that the apertures through which the caustic acts are brought forcibly in relation with the stricture which it should destroy.

Bougies numbering two, three, and four and a quarter millimetres each respectively, were first introduced, and immediately afterwards the olivary body of the porte-caustique was passed through the obstacle, after which it was drawn back, and pressed against the back part of the stricture, the caustic carried by its articulated stem being introduced through the oval apertures. It was brought into contact with the fibrous ring, and then withdrawn. After waiting two minutes to allow the cauterisation to take effect, I endeavoured to remove the tube; but the spongy tissue which surrounded the stricture was so swollen by the afflux of blood, that for three hours, in spite of oily injections, it prevented its withdrawal. Belladonna ointment was applied through the tube to the stricture, and rubbed in externally, but in vain. It was finally removed without much effort, after the patient had been in a bath for an hour. Had this failed, I should have surrounded the penis with ice, for if cold contracts the tissues, it also prevents the afflux of the fluids, and repels them from the parts on which it exerts its influence. The practice appears to me to be reasonable, as the afflux of blood in the spongy tissue was the cause of the turgescence which prevented the exit of the olivary body, and I should certainly have recourse to such a practice, if the same occurrence were to happen again.

Three other cauterisations were afterwards practised with the direct porte-caustique, at intervals of four days, after which bougies were introduced temporarily. The tissue of the stricture seemed to be softened, and yielded; the dilatation made progress; we reached as far as five millimetres, and then, in spite of the daily introduction of bougies, we lost ground, and fell back to three and a half millimetres. I proposed to the patient to attempt the resection of the inner ring, to which he readily assented, and I accordingly practised it. Immediately afterwards, a catheter of five and a half millimetres was introduced, and left in the passage. Another of seven millimetres was next used, and remained in three days; temporary dilatation for an hour at a time was then practised for a week, the stricture admitting an instrument of six millimetres at once.

While in this state, the deplorable accident of the Versailles railway happened. M. D—— had his left arm broken in two places, and was under the care of Professor Moreau for two months, during which time neither bougie nor any other dilating means was introduced; the urine passed sufficiently freely. The patient afterwards travelled for six months in Holland and Switzerland. When he returned he came to see me; he had not been once threatened with retention of urine. I examined the urethra; the projection was not effaced, but the passage was more open; it readily admitted an instrument of five millimetres. He then went back to Java, with directions to pass bougies every week to keep the canal so far dilated. The stricture at the curvature had entirely disappeared.

I have reported this case in detail, because it shows clearly the nature and effects of those strictures which are at once *callous* and *turgescent*, formed by the *fibrous* and *erectile* tissues; and because it demonstrates the danger of cauterisation in the spongy region, and the transformation under its influence from the turgescent to the fibrous condition.

ON THE NOXIOUS EFFECTS OF AMMONIACAL VAPOURS DISENGAGED FROM GUANO.

By G. C. WATSON, Esq., M.D.

The escape of ammoniacal gas from the ordinary guano of commerce is notorious enough, and the pungency keen in proportion to its rapid evolution; but the toxicological effects of this irritant gas, as developed from the manure, have not been noticed, so far as I know,[1] in any accredited way. I take the liberty, therefore, of placing on record, for practical purposes, and especially as facts relating to juridical medicine, the following observations, for the accuracy of which I can sufficiently vouch.

The port of Liverpool has lately been notorious for large importations of guano, either from Peru, which is considered the best in the market, or from the little barren island of Ichaboe, on the western shore of Africa, or from other islands along this coast similarly situated as to intertropical climate. The temperate zone, by its frequent or periodic rains, is unfavourable to the slow accumulation of the bird's dung, the deposit being washed away as soon as it falls, which is obviously the reason why the localities where this manure is found are always intertropical. The rain so washes out the more soluble salts of ammonia, soda, &c., that the valuable part of the substance to the agriculturist is removed, and the more earthy residue left is not worth the cost of conveyance.

The accumulation of this peculiar excrement under a burning sun, explains the mode of its concentration, the heat rapidly evaporating all the contained moisture, and promoting the formation of those crystalline deposits in which the virtue of the manure consists. As layer upon layer has thus hardened in the sun, and become successively a *super* and a *sub*-stratum, the more volatile salts of ammonia have been delayed in their escape by the encumbrance of moisture, and fresh layers, so as to form, along with the more fixed salts, such as the oxalates of ammonia, a mass dried and condensed by superincumbent pressure into a solid cake, which on the island of Ichaboe is so hard as to require the use of the pick-axe in order to break it for removal to the ship. At first the ships rejected the dry and crusted bed, and addressed themselves to the task of loading with the moister substance which lay nearer the water; but this error soon corrected itself.

This passing notice will enable those who may happen not to know much about the natural history

[1] I was unaware, when this was written, that a paper had appeared in the *Medical Times* of July 26, from the pen of Dr. Charles Kidd, on the noxious effects of guano. I need scarcely add, that I perfectly agree with his remarks, as well as the remedial agents used, in the case reported himyb.

of the guano soil, to perceive that in the act of digging up and removing hills, composed of beds fifteen or twenty feet deep of these volatile saline accumulations, it cannot be a matter of surprise that the labourers suffer severely from the liberation of irritant gas on disturbing these strata of nature's pliocene geology, her fossil penguin coprolites. The very atmosphere of the island is impregnated with vapours which ordinary nostrils would be inclined to sneeze at, and this, too, even on board the ships lying in the offing, a few miles out, whenever the wind carried the pungent stream in the direction of their anchorage; but when working at the "pits," as the beds of the guano are called, the effect must be something beyond a mere sneezing affair; and in reference to this ultra-sneezing point, I have the authority of Mr. Guthrie (the intelligent mate of a ship which went to Ichaboe and brought back a large cargo),[2] for stating that the effects were very severe upon many of the labourers taken out as stout able men for the purpose; sailors themselves making bad hands at the spade and pick-axe. These labourers suffered very much on first applying to their task; the vapours produced all the shades of irritation of the air-passages and their outlets, from simple lachrymation, coryza, titillation of the fauces, cough, and embarrassed respiration, to regular muco-purulent secretion, from some or all of these lining mucous surfaces; pain, or sense of tightness in the chest, and, in some cases, severe frontal pain, or sense of weight referrible to the region of the frontal sinuses; incessant cough, accompanied with expectoration streaked with bright arterial blood, as well as bleeding from the ears, mouth, or nostrils, from the two last so severe and prolonged as often to cause fainting. This latter mode of suffering from the hartshorn vapour was especially observed on first working at the pits early in the morning, after sleeping either on board, or in at least a more diluted atmosphere of ammonia under tents on shore. Before the island was cleared of its valuable coat of soil, several deaths had occurred, chiefly amongst the labourers, and though, without being able to ascertain with any exactness the causes of death, which, of course, in a tropical climate, are at all times referrible to fevers of one kind or other, or to those sudden and sharp inflammatory attacks of the vital organs, due to vicissitudes of diurnal temperature, hygrometric changes, and, perhaps, we should add, the peculiarly exposed and irregular life of seafaring men, yet it cannot be doubted that several, or some of those silent occupants of the little grave-yard at Ichaboe, had reason to date the secondary or proximate cause of their fatal illness to the noxious fumes of this very remarkable soil.[3]

I think, then, that, in the absence of direct proof, we may fairly assume that the acrid nature of these vapours was sufficient to account for death in some instances, although the mortal per centage amongst the sufferers cannot be now learnt, even approximatively. When we consider the constant daily (to say nothing of nightly) exposure of the air tubes and their approaches to the same sources of irritation, it is not difficult to satisfy our minds in strict accordance with chemical and physiological facts, that the mode by which a fatal issue to an early and slight irritation might be procured, would be due to the exposure of already inflamed surfaces to the repeated action of chemical effluvia, the first effect of which would be to excite the progressive phenomena of irritation and inflammation; and the second would follow up this first by a direct chemical effect operating upon exposed and abraded surfaces, so as to develope the features of that state termed "erosion" locally, with liquefaction of the blood generally.

From these data the following proposition may be derived:—"that, probably, in no case on the records of forensic medicine has there been so great and so continued an amount of mischief from ammoniacal gases as in the present instance."

Lest this should seem an exaggeration of facts, let the number of ships sent to this locality alone be ascertained, and, as I understand from persons present, a number hardly, if at all, short of a "thousand sail" will be found from first to last to have busied their hands in removing the dung of the African sea-fowl to a land of unrivalled plenty—depriving the barren rocks of Ichaboe of their adventitious covering, in order to enrich the famed shores of Old England—the "one talent," because useless where it lay buried, carried to the account and credit of the "ten."

It can be no wonder, then, that days passed in hard labour under a tropical sun should debilitate a frame, perhaps in many instances not free from the taint of disease, and that when we review the kind of compound exposure to which the frame was liable, exposed by day to toil in excessive heat and acrid fumes, by night to the cold winds and heavy dews, either on shore or afloat, to be followed up daily by the first morning shock of bleeding and fainting, can we wonder that under such inauspicious circumstances the nights should be passed (as is known to have been the case) in restlessness and fever; and that under such combined forces the delicate anatomy of the human frame should be injured, and that too often irretrievably? The little "grave-yard" at Ichaboe cannot now be interrogated, as I have said, but if it could, the number of victims England has sacrificed in some sense to her thirst for gain, would make the philanthropist pause ere he assented to an expedition to an inhospitable and disease-bearing coast in search of that substance at so great and precious a cost as the life of one human being, when the same ingredients essentially are within our reach at home; but the far-fetched and dearly earned ever bears the palm in a British market over the accessible home commodity.

How in this instance this is no libel on the mercantile world any more than in other cases may not here be discussed; it belongs to that new and important section of practical science—agricultural chemistry—whose wand, of more than magian power, will open up before our eyes, at home and within our very precincts, resources of fertilising agency, perhaps only typified by the stinking manure of the Guano Islands!

The shores of this "Fortune Isle" are now cleared, and other spots, as Soldanha Bay, &c., have to be ransacked for the second-best commodity; but the noxious effects of the compost are still plentiful. After the load has been dug from the pit, and safely deposited in the hold of the vessel, the ship must be trimmed at first whilst at anchor, or if on her homeward voyage a heavy sea run, or a breeze untrim her balance, the cargo-ballast must be trimmed as often as is needful, and the labourer's occupation must ever and anon be—whilst "his thoughts oft homeward veer"—to descend for a few brief moments to level the pungent and shifted material with his spade, his mouth and nostrils covered securely with a handkerchief; for the vapours in the ship's hold, with all but covered hatches on account of a heavy sea, are *irrespirable:* the pit on shore was a fit preparation for the poisonous pit of the hold; consequently, he can only stay down just as long as he can hold his breath; like a diver, his work is "adown below"—but there is no possible renewal of the air for him, and the guano labourer in the hold, for the moments of plying his spade, is worse than the negro in the close and impure atmosphere of the hold of a slave ship; but the former is a volunteer in the African Manure Fleet!

When the cargo gains the port, it must be placed in bags in order to be carted to the stores, and again the hold is busy with its occupants. But there is an improvement now; the labourer can work with open hatches, and he can breathe the diluted gas for a few seconds, though how he does so is a puzzle to those who know nothing about the guano when told of its unadulterated pungency; but let any one descend into the hold and stand on the guano heap beside the workmen, and his astonishment will know no bounds, for to him the diluted vapour is so excessively pungent, that to breathe a second or third time is impossible. A chemical friend once went down such a place with me, and though fond of a pinch of pungent snuff, and heeding not the fumes of his laboratory, yet the moment he got to the foot of the ladder he turned, without stopping one instant to look around, exclaiming that "he could not stand this!" I lingered a second or two, holding my breath, as it was not the first time I had visited such a scene, but immediately lachrymation and coughing came on, so that I was obliged to re-ascend, and we neither of us feel any wish to repeat the dose.

The history of guano-manure-gathering ends here; surely enough has already been brought forward. It is now divided into lots, sold, and dispersed abroad, still, in the acts of storing and warehousing, it may become a nuisance of no mean order, as the subjoined case will show:—Several months ago in a street of this town (Liverpool), near the centre of the population, some large cellars were let for guano stores, and here the article was stowed away. A short time after I was requested to give a medical certificate of nuisance, complained of in the first floor offices above the cellars, one of which was occupied by an artist as his "studio." On going there to inspect the rooms, the vapour proved to be so strong, that it was impossible to remain, and to run was the only thing for us. The chemical friend previously alluded to, Dr. B., was, at my request, also asked to certify as to the deleterious nature of the ammoniacal vapours in these offices, and we wrote out the certificate in the room, using an effort to stay whilst so doing. Lachrymation was produced to a painful degree; it was truly impossible to remain in the rooms for any length of time, even with windows and doors open; and to prove the deleterious effects of the *gas* when *diluted by as much ventilation* as possible, the occupant of each office suffered severely; one got inflammation of the bronchial tubes, if not of the structure of the lungs, presenting peculiar spasmodic cough and expectoration streaked with blood, hoarseness, pain over each side of the chest, coryza, with headache and sore eyes. The other was attacked by inflammation of the frontal sinuses, hoarseness and cough, but without bloody expectoration; I believe he did not recover the attack for two or three weeks. One was obliged to leave the town for a time, and the other was kept at home for some days under appropriate remedies.

It is a strange fact that, in the present state of our law, the chief magistrate has only jurisdiction over a *public* nuisance; this was pronounced by the competent authorities to be a *private* nuisance, and consequently remediable only by private suit at law.[4] For days matters, then, remained in statu quo, through differences between landlord, tenants, and sub-tenants; and in about a fortnight the guano was all removed, to bless, with its pungent graces, some other favoured spot. There can be little doubt, I think, that such a nuisance ought to be abated by summary process, instead of being left to be dealt with by the tardy hands of private indictment.

A canary-bird soon died from being left in the room day and night. An atmosphere of chlorine was resorted to, which cleansed the rooms.

There is another question on the guano subject which merits some inquiry at the hands of Government, and doubtless would obtrude itself upon their notice, if the whole thing were not a transient commerce. It is the occurrence of scurvy on board the Ichaboe ships on their return home. This was notorious in the port, and, like the other facts, so well known, that it is possible no record of the fact may have found its way to suitable channels of medical science, beyond the current tradition of the hour.

One case was said to have occurred, where all the crew were so diseased as to be unable to work the ship, and fresh hands had to be obtained at some port in the Channel, in order to work the ship to Liverpool. Whether this sea-scurvy was owing to the inferior quality of the provisions, or to short quantity, is not ascertained, as far as I can learn; or whether the remoter effects of the guano could operate so specifically or not, by diminishing the vitality of the blood. Perhaps some share ought to be attributed to the debilitating labours on the

[2] The same party brought me the "Canadian Resin," the analysis, &c., of which was reported to the Liverpool Literary and Philosophical Society, and is printed in their Transactions for 1844 and 1845.

[3] Some fell in quarrels for precedency amongst the crews of the various ships, which were at one time carried to such a height that a war steamer was sent there to keep the peace.

[4] A paragraph noticing the above facts, as a subject of mercantile interest, was put in the *Times* a week or two after.

island, along with limit of fresh provisions, owing to the ships waiting two or three months sometimes at anchorage, for their turn at the landing-stages, the only approach to the island, which the early ships rigged out for their own service, and then bequeathed to their successors on payment of a certain fine, unless, as happened more than once, when the landing-place was carried by a *coup-de-main*. During their stay, in most of the ships water was very scarce; and, in some instances, vessels had to run for water to St. Helena or the nearest port, or to pay dearly for a supply from ships which arrived after them. There were times, as I am informed, when money could not purchase it.

It is painful to suppose, in the absence of any fuller information on the subject, that our fiscal regulations may be at fault in this particular; such is the impression given to me, after all possible inquiry has been made on this head. There is no reason apparent in the nature of the case, why ships should run short when often they had no cargo out, at least to any extent; but, possibly, the Customs did not, or could not, make any extra allowance of provisions for lying off some months at the island, waiting their turn, in addition to the voyage out and home, which would amount to *several months' absence*, so that even the ordinary allowance for the most distant port could hardly meet the requirements of the case, supposing that, by a happy fiction, like those of the law, they were to enter out for "*the longest port*." If mercantile pursuit of gain, and Custom regulations, both tend to press injuriously upon the ignorant sailor or labourer, the "hireling is oppressed in his wages," and a remedy must be sought; or if he get full wages, but forfeit life or health through excess of risk, which could have been mitigated, is it not the worthy object of a paternal Government to economise the life of its subjects? For the law of the land lays down the proposition in the statute-book, that a subject may not make away with his or her life, because such is a loss to the state, consequently, this is "an indictable misdemeanour." These remarks are longer than may appear needful, except in the large and philanthropic sense; but they are offered in the way of duty to the profession, with a full belief in their accuracy, and without wishing to give any offence to parties concerned, beyond what the acting upon conviction of duty in pointing out error or wrong may inseparably entail upon itself; in which case, if any be aggrieved, let it be with the fault itself, and not with the writer who holds himself bound fearlessly to do all he ventures simply as a duty, with all charity and good-will.

P. S.—The preservative effects of guano in mummifying bodies are sufficiently proved by the Ichaboe mummy of a man now going about the country, which had been buried about ninety years ago, and which is briefly noticed in the report before alluded to of the Liverpool Philosophical Society.

Bedford-street North, Liverpool.

PENCILLINGS OF EMINENT MEDICAL MEN.

PHILIP PINEL.

(Concluded from page 450.)

The number and the solid worth of Pinel's writings, the talents of his pupils, and the respect which attached them to his person and doctrines, all assisted in forming, in the very centre of the Parisian school, what was at that time called the "school of Pinel," in contradistinction to the school at La Charité, of which Corvisart was the chief. Neither Corvisart nor Pinel intended this rivalry unworthy of their noble characters. Pinel would not suffer any one to breathe a word against Corvisart in his presence; Corvisart repressed, with his utmost severity, the shade of an insinuation against Pinel. But they were equally the idols of their pupils. There was this difference between them: M. Corvisart's impulse supplied the place of study; M. Pinel's study that of impulse. We see on the one side all that nature was capable of; on the other, all that can be done by art. The talents of both were perhaps equal. On seeing a body, Corvisart *declared* the subject to have died of indigestion. At the sight of a supposed phthisical patient, Pinel *judged* that the disease was in the stomach; both were right, but Corvisart *guessed*, Pinel *concluded*; the one reached the truth by his instinct, the other by induction. Both arrive at the end with the same certainty, and with almost the same promptitude. Corvisart had in his character a *force* which carried him always in the first rank. When, some years after the decennial prize was to be awarded, the same causes produced the same rivalry between them, other works were forgotten to compare the "Traité des Maladies du Cœur," with the "Nosographie Philosophique." Hallé was the judge, and dared not decide, and, perhaps, the whole Academy, formed into a tribunal to judge so delicate a cause, would have manifested the same indecision. The different productions of the mind are, without doubt, of very unequal value; but how are they to be measured? and if the men thus compared are both of superior talents, how is one to be sacrificed to the other? In this case, Corvisart was too generous, Pinel too modest, and both were too just to wish to carry off the prize the one from the other.

We will now point out a few of the minor points on which they differed. Corvisart had little faith in the simplicity of diseases, and, consequently, in the possibility of a good nosological arrangement. Is it possible that what appeared simple to Pinel, seemed complex to Corvisart? Who can now judge and decide between them? In the second place, Corvisart admitted what experience did not permit him, and, in fact, permits no one, to reject. I mean the alterations of the fluids in disease. He was a *humorist*. He believed in the cachexies without disavowing altogether the part taken by the solids, either in the production or the cure of diseases. This doctrine was then one of mingled *humorism and solidism*. Pinel, on the contrary, was a solidist almost without restriction; not that he wished to deny altogether the alteration in the humours, but this alteration, according to him, was always secondary, and subordinate to the disturbance of the solids. He thus formally expressed his opinions at the introductory lecture towards the end of 1805:—"But this disturbance of the solids, whence comes it? from an alteration of vital properties? And this alteration, whence its cause?" This question Pinel leaves undecided. He rejected the cachexies as imaginary, and in his nosography he made a class for general organic lesions, such as scurvy. Is not this to admit under one name what he rejected under another, and thus to fall into a manifest contradiction?

It was in points such as these that Pinel's logic, otherwise so sound, lost in some degree its solidity, and turned him from one object only to draw him towards an equivalent one. He avoided the *name* without avoiding the *thing*. To this fault we must add that of having affected in his works a brusque style, without connection or coherence, and deprived of grace and ease. He wished, after the example of botany and natural history, to make a language for medicine entirely in substantives, without verbs or conjunctions. He flattered himself by this means to obtain the energetic conciseness of aphorisms. But conciseness does not exclude the common ties of words; and for want of these necessary ties, Pinel's sentences, dry and meagre, have sometimes a jostling sound which renders them fatiguing. His interrogatories are also too frequent, and this has taken something from the clearness of his writings. It seems as if Pinel had accustomed himself to think internally, and not in words; and by this means, when he wished to express his thoughts, words were wanting. To express himself with proper freedom on any subject, it was necessary that his heart should be interested in it. Those who consulted him on their diseases, or on those of their friends, quitted his presence touched by the softness, the varied flow, and the harmony of his words; his kindness made him eloquent.

Pinel was a member of the Legion of Honour, member of the Institute, chief physician to the Salpêtrière, and professor at the first school, and afterwards at the Faculty of Medicine of Paris. When this faculty was reformed in 1822, Pinel was made an honorary professor. The august founder of the Academy named him among its honorary members. His Royal Highness the Dauphin of France went to visit the Salpêtrière, and the next day Pinel received the grand order of St. Michael. He was of short stature, lively physiognomy, an impatient temperament, and singularly active constitution. He idolised the talent of Rousseau, and it is related of him that, after going in 1778 with M. Chaptal to see the remains of this great author, he passed five days and nights without sleeping, and that on his return to Paris, far from yielding to fatigue, he gave his lectures as usual. In 1823 he had a first attack of apoplexy. Scarcely was he convalescent, and even still very weak, when he chose again to visit his patients; but he was soon obliged to retire from active life. At length, in spite of the cares of his numerous pupils, who are at present the ornaments of medicine, and who crowded round his death-bed, an attack of apoplexy carried him off on the 25th of October, 1826. If his loss has been felt by science, it has been still more so by his family, or, what is the same thing, by that crowd of unfortunate sick to whom he was the father and the benefactor. At the news of this fatal event, a general cry of grief resounded through the wards of the hospital. Deputations from the Institutes, the Academy, the Faculty attended his remains to the grave. In the midst of this solemn assembly, which was enlarged by the hospital staffs, and persons of all classes, crowds of the sick, and even some suffering from paralysis, were seen to drag themselves to the tomb. What honour to his memory! The *savans*, by their eulogies, rendered honour to his genius; the poor by their grief rendered honour to his kindness!

Pinel was married twice; he left a widow, whose cares had softened the infirmities of his latter years, and two sons, happy in feeling the name they bore to be the most honorable portion of their heritage.

Philip Pinel published "Institutions de Médicine Pratique" (1781), translated from Cullen's English work; "G. Baglivi, opera omnia medica, practica et anatomica, novam editionem mendis innumeris expurgatam, notis illustravit et præfatus est Ph. Pinel" (1788); "Nosographie philosophique, ou méthode de l'analyse appliquée à la médecine" (1798), "Traité médico-philosophique sur l'aliénation mentale" (1801); "La médicine clinique rendue plus précise et plus exacte par l'application de l'analyse, ou recueil et résultat d'observations sur les maladies aiguës, faites à la Salpêtrière" (1802); "Discours inaugural sur la nécessité de rappeler l'enseignement de la médecine aux principes de l'observation" (1806); "Abrégé des transactions philosophiques, dirigé par Gibelin." (1791).

Pinel also inserted papers in various scientific works, as follow:

"Mémoire sur l'application des mathématiques au corps humain, et sur le mécanisme des luxations;" "Mémoire sur le mécanisme des luxations de l'humerus;" "Mémoire sur les vices originaires de conformation des parties génitales, et sur les caractères apparents ou réels des hermaphrodites;" "Mémoire sur le mécanisme des luxations des doux os de l'avant bras, le cubitus et le radius;" "Mémoires sur les moyens de préparer les quadrupèdes et les oiseaux destinés à former des collections d'histoire naturelle."—(*Journal de Physique*, 1787—89.)

"Mémoire sur une nouvelle méthode de classification les quadrupedes, fondée sur les rapports de structure mécanique que présente l'articulation de la mâchoire inférieure."—(*Actes de la Société d'histoire naturel de le Paris*, 1792.)

"Observations sur une espece particuliere de mélancolie qui conduit au suicide;" "Réflexions sur les buanderies, comme objet d'économie domestique et de salubrité;" "Exemples frappants de l'abus de la saignée dans les maladies aiguës de la poitrine;" "Recherches sur l'étiologie ou le mécanisme de la luxation de la mâchoire inférieure."—(*Médécine éclairée par les sciences physiques*, 1791.)

"Mémoire sur la manie périodique ou intermittente;" "Recherches et observations sur le traitement moral des aliénés;" "Nouvelles observations sur la conformation des os de la tête de l'éléphant;" "Observations sur les aliénés et leurs divisions en espèces distinctes;" "Sur les vices originaires de conformations des parties génitales de l'homme et sur le caractere apparent des hermaphrodites;" "Résultats d'observations pour servir de base aux rapports juridiques dans les ca

d'aliénation mentale."—(*Mémoires de la Société médicale d'émulation*, 1798—1817.)

"Résultats d'observations et construction des tables pour servir à déterminer le dégré de probabilité de la guérison des aliénes."—(*Mémoires de l'Institut*, 1807.)

Pinel was editor of the *Gazette de Santé*; he wrote articles in the *Encyclopédie Méthodique* on medical subjects; and in the *Dictionnaire des Sciences Médicales*, both alone and assisted by Bricheteau.

PROGRESS OF FRENCH SCIENCE.

(FROM OUR OWN CORRESPONDENT.)

Paris, September 5, 1845.

Academy of Medicine; Meeting of September 1, 1845; M. E. de Beaumont in the chair. G. B. Airy, Esq., F.R.S., Director of the Greenwich Observatory, was present.

M. Ebelmen on the Production of Hydrophanous Bodies.—At the last meeting, a communication was made by Professor Arago, in M. Ebelmen's name, relative to the deposition of silicious masses from the evaporation of silicic ether in a moist atmosphere; when this substance contains a small quantity of chloride of silicium, evaporation causes the formation of true hydrophanous matter, perfectly opaque when dry, and acquiring transparency when placed in contact with water. The following interesting result is also brought forward by the same chemist:—Having closed a phial of silicic ether with a cork previously used for creosote, he observed that under the influence of a trifling amount of organic matter, a deposit was formed in the ether, similar in composition to the fossil shells of inferior animals in a state of petrifaction. This is the substance called *calcédoine* by French chemists.

Nerves of Serous Membranes.—M. Bourgery read the first part of an interesting anatomical memoir on this subject. When the paper is concluded, we will present an abstract to the readers of the *Medical Times*.

Sir H. Davy's Safety Lamp.—Miners have in general a very great aversion to use this instrument on account of the dimness of the light it conveys, and yet the importance of its adoption is admitted by all, and is rendered still more urgent by recent statistical accounts, wherein it is proved that no less than 7,000 lives are yearly sacrificed in the various mines in Europe, by the negligence of the men, who prefer incurring positive risk, to subjecting themselves to trifling inconvenience. A letter from M. Boussingault relates a recent accident of the nature of those referred to, which occurred at Wissemburg. The men were returning to their work, the foremost miner bearing a common lamp, by which an explosion was immediately produced. The bearer of the light escaped uninjured. The man who followed was only slightly hurt, but the five others were killed on the spot. M. Boussingault immediately instituted a series of experiments on the degree of protection afforded by Sir H. Davy's lamp. He threw sulphuric ether upon it, and the ether did not take fire; he introduced the lamp in an atmosphere of detonating gas, and no explosion took place. M. B. concludes the use of the miner's lamp should be enforced by persons in authority in all mines, and hints at the possibility of lighting the vaults by electric agency, the flame being contained in glass lanterns exhausted of their air. This plan is doubtless open to many objections, some of them even insuperable—the fragility of the lanterns, for instance. The object of M. B.'s researches is, however, so important, that they are deserving of every encouragement, and we can only hope they will meet with the success they merit.

Academy of Medicine; Meeting of September 2, 1845; Dr. Roche, Vice-President, in the chair.

Intestinal Suture.—An elaborate and interesting report was read by Dr. Jobert, on a new plan of intestinal suture proposed by M. Moreau Boutard. The following is a summary of the report:—When an intestinal wound is united, its lips become puffed, and form a sort of mucous *pad* (bourelet), which M. Moreau Boutard removes by excision; he then joins the serous intestinal surface of one lip with the submucous tissue of the other, and maintains them in apposition by a suture. He presented nineteen experiments on dogs, in support of this plan, and submitted to the Academy four anatomical preparations. It is a report on this operation which M. Jobert brings forward. After disapproving of the excision of the mucous *pad*, as being next to impossible to perform in man, and as a dangerous practice, exposing the intestine to gangrene, by the removal of vascular connections; the reporter further considered the proposed operation as a dangerous one, offering great chances of abnormal anus. The reporter, after enumerating the various intestinal sutures proposed by T. and B. Bell, Travers, Sir A. Cooper, Smyth (of Philadelphia), Louis, Lapeytonie, and others, proceeded to remark, that down to the last few years, surgeons were not guided by any fixed principles in the suture of intestines, and that the operation was generally abandoned to the inspiration of the moment. Three methods may be said to have outlived all others, and to unite the various modes of intestinal suture at present in practice:—1, Union of structures of the same nature (*i. e.*, serous surfaces); 2, union of the serous, mucous, and muscular tissues with each other; 3, union of the serous surface with the submucous cellular layer. M. Jobert does not think that one form of suture is applicable to all cases, but that the stitches should vary with the shape and condition of the wound. M. Jobert closes his report by the appreciation of the three following sutures:—1. M. Denan's supports the intestinal walls by a foreign body, and always seeks to obtain the contact of the serous surfaces; this operation has been successful on dogs, but who will not fear producing even a limited gangrene of the intestine in man? 2. M. Gely employs a suture, the object of which is to replace the union by the invagination of the gut, and to ensure the removal of the threads with the fæces. His stitch is very like that used by cobblers; it is called "suture en pique." M. Jobert has carefully examined it, and finds it causes valves to form in the cavity of the intestine, valves which time does not diminish, and which may occasion serious accidents by retention. M. J. would not advise its use, except in wounds of small dimensions. 3. M. Reybard's operation, the endeavour to obtain union by the first intention, by the exact apposition of the lips of the wound, M. Jobert considers impracticable in man, on account of the thinness of the intestinal wall. A new suture, successful in three cases, has been lately proposed by Professor Nunciante, of Naples. The thread forms a spiral, alternately passing from left to right, and from right to left, leaving its ends in the angles of the wounds, each in a different lip, so that traction on the threads must produce inversion and apposition of the serous surfaces.

Intermittent Fever and Tubercular Consumption.—It has been of late frequently asserted that these two maladies are not met in the same localities, and a recent memoir read to the Academy, goes so far as to deny the possibility of finding in marshy districts any proportion of tubercular patients, to be compared to the numbers who are victims to consumption in other provinces. This startling assertion was made with such confidence, that the Academy requested the physicians practising in countries where intermittent fevers are endemic, to report the result of their experience and researches on this important subject. Dr. A. Lefevre, physician to the naval hospital at Rochefort, a city where ague is observed in its severest forms all the year round, forwards to the Academy statistics on the point under discussion. Out of 30 deaths in his own practice, 10 were undoubted cases of pulmonary consumption. The case-book of the hospital makes mention of 615 dissections, where tubercles were detected 105 times in the lungs, and 27 times in other viscera, forming altogether an amount of 142 cases of tubercular disease out of 645 deaths; *i. e.*, rather more than one-fifth, a result quite contradictory to the alleged antagonism of phthisis and ague.

HOPITAL ST. LOUIS—M. JOBERT.

Paralysis of the Serratus Magnus.—George D——, ætat. 23, a locksmith, entered the hospital on July 1, 1845. This man, of an athletic constitution, has not been at any time affected with syphilis, neither has he ever been submitted to the deleterious influence of preparations of lead. Accustomed to employ a hammer weighing six pounds, he exchanged it seven weeks before his admission for an instrument weighing eighteen pounds, and, two days after, experienced sudden loss of power of the right arm, and great difficulty in the elevation of the limb. The shoulder became painful, although the pain was not so intense as to oblige him to discontinue his labour. A fortnight before he entered the hospital his companions noticed a marked swelling of the right shoulder, and attributed the deformity to dislocation of the arm. On examination, the head and body being erect, and both arms hanging down, the right scapula was found to be raised from the thorax, the right shoulder higher than the left by fifteen lines, and the inferior angle of the scapula of the affected side eight lines nearer to the vertebral column than the inferior angle of the bone on the healthy side. The deformity was considerably increased on the arms being carried horizontally forwards. The inferior angle of the right scapula was two inches and nine lines nearer to the spinous processes of the dorsal vertebræ, than on the left side; for the superior posterior angle the difference was of six lines only. *Pain* was experienced in three distinct regions; at the anterior insertions of the serratus magnus, at the lower angle of the scapula, and towards the internal edge of the acromion process. The voluntary *movements* of the arm were impaired. The strongest efforts of the patient do not succeed in raising the limb to an angle of more than 45 deg. with the thorax; but *the scapula being firmly pressed by an assistant against the ribs*, and *maintained in its position*, the movements of the arm were almost completely restored, and the patient could at will raise the limb or carry it forward. The general condition of the patient offers no detail worth noting. The diagnosis of this singular affection chiefly rests upon the peculiar deformity of the scapular region, and upon the restoration of voluntary movement when the bone is fixed. The treatment hitherto pursued has not yet been productive of any marked beneficial results. Shower and vapour baths, stimulating frictions, blisters, moxas, and cupping, have all been resorted to without success. M. Jobert intends applying a stronger revulsion with the actual cautery. We shall report the results of cauterisation in this interesting case.

HOPITAL DES ENFANS.—M. GUERSANT.

Foreign Body in the Trachea; Operation.—A little girl, aged four years and a-half, was brought to the hospital on the 12th of August; she had, in play, swallowed a bean, which had entered the larynx, and which, notwithstanding the exhibition of several emetics, had not been expelled. The child was troubled with violent fits of coughing, followed by periods of calm; the face was a little injected; the chest yielded a natural sound on percussion, and slight mucous and sibilous râles were distinct on both sides of the thorax, both in front and in the back. The foreign body was distinctly felt moving up and down in the trachea, particularly during the cough. The diagnosis being fully established by the physical signs, as well as the history of the case, tracheotomy was decided on. The operation was rapidly performed, and was attended with an unimportant hemorrhage. We noticed the incision of the trachea not being quite large enough to permit the extraction of the bean—it was enlarged, and the foreign body was expelled by a strong effort of expiration. The wound united rapidly by granulation, and ten days after the operation the child was sent home cured.

LA CHARITE.—PROFESSOR VELPEAU.

Fibrous Tumours of the Uterus; Clinical Lecture.—Fibrous bodies occurring in the walls of the womb, form one of the most commonly observed diseases of that viscus, in the parietes of which they frequently grow without betraying, at least for a long time, their presence by any symptom. These tumours lie encircled by the muscular structure of the viscus, with which they are never continuous, and can generally be easily enucleated; they occasionally attain an immense size, and some have been found to weigh no less than sixty pounds; it is a common occurrence to find them equal in size to the head of an adult. Their structure is not vascular, and they are never the seat of pain. During the first years of their existence these fibrous nuclei are seldom detected, on account of the impossibility of the exploration of the walls of

the womb, and of the vague nature of functional disorders produced in the organs of generation. The symptoms they occasion are chiefly—frequent hemorrhage; a sense of weight towards the anus, attended with obstinate constipation; pain in the inguinal regions; exploration per vaginam will prevent confusion with any disease whatever of the os tincæ, *i. e.*, cancer, granulations, &c., and the absence of nervous disorder, a distinguishing symptom of the deviations of the uterus, will also assist the diagnosis. When a tumour situated in the pelvis in front of the womb, and adhering to it, has acquired a considerable size, it becomes often a matter of difficulty to ascertain if the complaint had its origin in a fibrous nucleus of the nature of those we are describing, or if it is the result of an ovarian disease. The recollections of the patient must here be brought in to facilitate the investigation. Ovarian tumours invariably have their origin in the lateral and inferior abdominal regions, from which they have gradually descended into the pelvis; the uterine tumour, on the contrary, arises from the centre of the hypogastrium; a valuable diagnostic sign. Intestinal or peritoneal tumours cannot be confounded with those under consideration: 1st, because their appearance must have been accompanied or preceded by morbid changes in the digestive functions, the recollection of which will lead to a correct appreciation of the nature of the case; 2nd, because intestinal or peritoneal tumours do not give rise to uterine hemorrhage, and whitish discharges so commonly observed as consequences of the existence of fibrous bodies in the uterine structure. Such are the leading characters of the first period of the existence of these tumours of the womb, the diagnosis of which is far more important in their incipient state than at a further stage of their existence.

Preservation of the Intelligence in a Case of Wound of the Brain.—M. P., ætat. 44, was the last of an unfortunate family singularly addicted to suicide; the father, a brother, and two sisters, although in good circumstances, and without any known cause of sorrow, had all committed suicide. On March 8th, 1845, M. P. endeavoured to put an end to his life by firing, at the same time, two pocket-pistols, one directed to each temple. One of the shots singed the skin of the forehead without causing any material injury; but the right bullet took a more fatal course, having perforated the temporal bone, and penetrated into the substance of the brain. The unfortunate man did not, it seems, lose consciousness, for, on being brought home in a carriage, he told his friends to pay the driver two francs and a half, the price agreed upon when he was placed in the coach. He recognised his friends, and his speech remained free and unimpaired. Dr. Trélat, on being called to the patient, found the left arm deprived of sensation and motion, and the left leg quite insensible, but still capable of some voluntary motion. On the 17th of March he expired; but up to the 15th he understood all that was said about him, and answered every question. Sight, taste, hearing, and olfaction were all preserved. The post-mortem examination shewed the ball had merely perforated the skull, forming a neat round hole in the temporal bone, without any stellated fracture or splitting—penetrated in to the fissure of Sylvius, passing between the middle artery of the dura mater and its branches, without injuring any of them,—traversed diagonally the right lateral ventricle, and lodged itself under the membranes, close to the falx cerebri, the resistance of which had arrested its further progress. The cerebral membranes were found inflamed, and the substance of the brain firm and healthy, free from any injection, and even from that appearance called "piquet."

DAN. M'CARTHY, D.M.P.
President of the Parisian Medical Society, late Interne of the Hospitals of Paris.

We regret to hear that Mr. Thomas Wakley, M.P., has had an attack of apoplexy, accompanied by paralysis, during his sojourn in the Isle of Skye. His duties as coroner are performed by Mr. Mills, a gentleman not belonging to the medical profession, but who has acted for Mr. W. as clerk and reporter for the press for a considerable time.

PROGRESS OF GERMAN MEDICAL SCIENCE.

By SIGISMUND SUTRO, M.D.

Cases of Poisoning—Poisoning by Sugar of Lead.—A girl, ætat. 24, took half an ounce of sugar of lead by mistake for Glauber's salt. Violent burning of the stomach, sickness, and vomiting was immediately produced. A quarter of an hour after the author found her with increased redness of the face, violent pulsation of the carotids, the ephithelium of the mouth white, the epigastric region very sensitive, skin dry, pulse accelerated, small, and weak. An emetic of ipecacuanha was ordered, and vomiting kept up by abundant draughts of milk. A violent diarrhœa, with slight colic, supervened. With vegetable diet the patient recovered in a few days.

Poisoning with Vinegar.—Though Christison denies the poisonous property of acetic acid, the author considers the following case as a proof of this action. A man, ætat. 36, recovering from pleuropneumonia, took, instead of a teaspoonful of aqua laurocerasi, the aromatic vinegar only destined for smelling. He jumped out of the bed instantly, and lay writhing in the most excruciating pain on the ground; he also drank a large quantity of water. When the author arrived, he found the epithelium of the mouth white, violent pain in the chest and stomach, sickness, profuse perspiration. Pulse very accelerated, small, and contracted. Milk was given with carbonate of magnesia, and an emulsion. After frequent vomiting and diarrhœa the pains diminished, and the patient recovered.

Poisoning by Digitalis Purpurea.—A man, ætat. 24, was treated for hypertrophy of the heart and disease of the mitral valve, with fox-glove, which, after thirty-two grains had been taken in the form of powder, and three drachms in the form of infusion, occasioned slight symptoms of intoxication, easily removed by means of an oily emulsion. The same patient was again obliged to take fox-glove three months afterwards, when, after the use of one drachm of the infusion, a complete poisoning ensued, in the first stage of which, increase of the urinary secretion was the most prominent symptom. The second stage was short, and the third was developed very rapidly. The patient neither complained of dryness of the mouth, sickness, nor digestive disturbance, and though the pulse was scarcely diminished in frequency, he was in a tetanic and unconscious state soon after he first felt any affection of the head. An accumulation of fox-glove in the body must have occurred (as with mercurial preparations), by which means the rapid development of the third degree took place.

Poisoning by the Berries of Belladonna.—Two girls, of eight and five years of age, ate some belladonna berries; four hours afterwards they were stupefied, unconscious, and struggled with their hands and feet. The pupils were much dilated, the look staring, the power of speech and sensibility were lost. An emetic was administered with great difficulty, which caused several pieces of the berries to be discharged. The author then ordered a teaspoonful of castor-oil, with clysters. Sensibility returned by degrees; speech was perfect after twenty-four hours, and the hearing became regular much before vision.—*Dr. Mellon, of Treudenthal, in Prag. Viertcljahrscrift.*

Poisoning by Putrid Herrings.—P. Frank has already noticed the injurious effects of putrid herrings, the brine obtaining a caustic acrimony after a lengthened period. A healthy woman, ætat. 30, dined off a few pieces of herring with a good appetite, although they had a putrid smell and mawkish taste. Soon afterwards symptoms of intoxication appeared; weight at the stomach; violent thirst; feeling of cold and dejection; anorexia and vertigo were added towards the evening, so that the slightest movement caused her to fall to the ground. This feeling of dejection gradually passed into insensibility; cold perspiration ensued on the face; the pupils became dilated, and the pulse imperceptible. When the patient was brought into the fresh air, she vomited a great quantity of an almost colourless liquid, mixed with mucus and chyme, whereupon sensibility returned. Now the second stage of the poisoning begun; very insupportable excruciating colic appearing in paroxysms; great sensitiveness over the abdomen. The intermissions were very short. During the paroxysms the muscles of the face were drawn, the lips contracted, and teeth spasmodically closed; nausea; pulse weak and thready, 100 per minute; the whole body covered with cold perspiration. The patient obstinately refused to take anything, even a drop of water. After the paroxysms had lasted half an hour, the pains gradually diminished. A warm perspiration appeared all over the body; the pulse improved; sleep ensued; and the patient took afterwards a powder of magister. bismuth. c. ext. hyoscyam. The next day sickness, and a slight sense of weight at the stomach were still present, but soon disappeared. Two other persons who had likewise partaken of these herrings (but, probably, less putrified portions), were inconvenienced by a sense of weight at the stomach, lasting for several hours.—*Dr. Tayrer, ibidem.*

Some Observations on the Epidemic of Intermittent Fever, which raged in the Summer of 1842 at the Manufactories of Zarewa and Wasnescinok, near Moskwa.—This epidemic was so considerable that the author had to treat about two thousand patients in five months. In three cases complete aphonia appeared with the first paroxysm; the tongue was moveable and consciousness undisturbed. The skin was very sensitive, and the ileo-cœcal region presented a similar noise to that heard in abdominal typhus. After a mustard poultice had been applied this region, one patient began to stammer. At the end of the paroxysm the power of speech gradually returned, but irritability and excitable temper generally took the place of the paroxysm. In the following attacks—consciousness was slightly affected, the intermissions became shorter, murmuring delirium was present, and two patients died at the climax of the fourth paroxysm. The different pains of the head, throat, testicles, &c., accompanying this epidemic, frequently required local abstraction of blood. Many cases resembled typhus abdominalis at first. Pain of the thoracic vertebræ was rarely perceived, and had no influence on the treatment. Swelling of the liver and spleen was equally rare and slight; but pain at the pit of the stomach was almost constant. Towards the end of July and August a papular eruption appeared frequently in and about the mouth, with the first paroxysms, or two or four days after the removal of the fever, with great heat and sensibility of the mouth, and previous swelling of the lips. This eruption, which generally caused great relief, either passed off quickly, or returned several times, and then remained from four to six days. An infant and his mother were both simultaneously affected with a quotidian intermittent, but, after the mother had taken two doses of quinine, both were cured. In another case, however, the child could not be cured without itself taking quinine. The convalescence was generally accompanied by weakness and heaviness of the head, which were removed by means of local sanguineous depletions, valerian, and ether. The sulphate of quinine acted better, at the dose of two grains every two hours, than at four grains every four hours. Immediately before or after paroxysms its effects were uncertain, even in large doses; in pills it was less efficacious. Prussiate of iron, from two to four grains every two hours, only removed one series of symptoms, and caused the other to be more prominent. The *chinoidine* did not at all answer the expectations entertained of its efficacy. *Indigo*, five to ten grains every two hours, exerted a visible influence on the fever (from forty to eighty grains were taken altogether). The solutio arsenicalis Heimii was only four times inefficacious in fifty-four cases; half a drachm (eight to fifteen drops three to four times a-day) was generally sufficient, but relapses were not uncommon. No injurious consequences were observed from this remedy.—*Dr. Von Guttceit in Medicine Zeitung Russlands.*

Hermippus.—The following observation shows the injurious effects of old people causing children and grand-children to sleep in the same bed with them. The wife of a peasant, upwards of seventy years of age, had shared her husband's bed for half a century, when she became a widow. Afraid of sleeping by herself, she desired her youngest son, ætat. 27, strong and healthy, to sleep with her. Three months after, the young man sought the author's advice, because he perceived a feeling of

bodily weakness increase every day. His sallow appearance confirmed his statement; but no peculiar disorder could be discovered, till it was found out that since his father's death he slept in the same bed with his aged mother, who had increased in health and spirits perceptibly. The problem was now solved. The patient got a simple tonic; was advised to adhere to a substantial diet; to take half a dozen salt baths, and to sleep henceforth by himself. This soon had the desired effect; he became as healthy and blooming as he ever had been. The revival of the mother did not continue; she died a year afterwards.—*Dr. Cramer, of Aschersleben, in Casper's Wochenschrift.*

PROGRESS OF IRISH MEDICAL SCIENCE.

(FROM OUR OWN CORRESPONDENT.)

Dublin, Sept. 6.

Excision of the Lower Maxilla.—This operation was performed on Monday last at the Meath Hospital by Mr. Rynd, for the removal of a large osteo-sarcomatous tumour, occupying the left side of the face, and exhibited, in the method pursued in its performance, one or two peculiarities that may not be uninteresting to the profession. The subject of the operation, a female, aged twenty-four, came from the Isle of Man, and was admitted to the hospital about a fortnight since. The tumour, now of eight years' standing, had commenced as a very small prominence, having during this period gradually obtained its present bulk; the comparative measurements of the diseased and healthy sides being as follow:

From the zygoma to the symphysis menti, over the most prominent part of the tumour, eight inches and a half, the corresponding measurement of the sound side being six inches; from the angle of the jaw to that of the mouth, across the tumour, six inches and three-quarters, corresponding measurement of the healthy side three inches and one-eighth; circumference of the tumour round its base sixteen inches. Its growth had been unattended by any considerable pain or constitutional disturbance, but the patient sought for its removal from the impediment to deglutition and respiration produced by its pressure on the neighbouring organs. Fits of most distressing dyspnœa had latterly occurred during the night. An issue had been made in the fundus of the tumour some time ago by a medical man—for what purpose it cannot well be conceived—which, however, healed soon after, the discharge having been very trifling, and accompanied, according to her own account, with an escape of some fragments of bone, but the subsequent examination of the maxilla detected no appearance of exfoliation. The first incision was made by Mr. Rynd over the symphysis, in preference to the more usual method of commencing at the angle of the mouth, and instead of including the tumour in two semicircular incisions, as suggested by some of the gentlemen present, for the purpose of avoiding a redundancy of integument. Mr. Rynd, believing that considerable shrinking of the soft parts would take place, rejected this precaution, and cut, first, in a vertical direction downwards from over the prominence of the joint for a short distance, then with a semicircular sweep, to meet the angle of the flap made by the perpendicular incision at the symphysis. The disease having been found now to have involved a considerable portion of the bone at the right of the symphysis, the bone was sawn across at this part, and an incision having next been made to separate the base of the tumour at its connection in the neck, the diseased mass was dissected out. It now remained only to finish the operation at the joint, and, in order to effect this without risk of wounding the internal maxillary artery, it occurred to Mr. Rynd, a few days before the operation, to have an instrument constructed, the use of which might be expected to guard him effectually from the occurrence of this accident. The instrument closely resembles the ordinary dressing spatula, being somewhat thicker, blunt at the edges, but with its rounded extremity made sharp enough for cutting. This Mr. Rynd passed between the bone, the internal pterygoid, the internal maxillary artery, and the other structures on its inner side, loosening their connection with the ramus of the jaw, and then cut into the joint from its anterior aspect, and so completed the operation. The edges of the wound, brought in contact by means of the interrupted sutures, have almost completely united by the first intention, and the patient's progress has been in every respect completely satisfactory.

A longitudinal section of the tumour, which weighed about a pound and a half, exhibited the diseased mass of a reddish-white homogeneous appearance, somewhat more consistent than fat, replacing the central structure of the bone, and surrounded by its cortical substance, reduced to a mere shell. A cavity of smaller size, at the base of the maxilla, contained some ounces of a dark-coloured grumous fluid.

Effects of large Doses of Ether in cases of Enlarged Spleen.—In an account of some cases of ague, treated by Dr. Corrigan at the Whitworth Hospital, and recorded in the *Hospital Gazette*, he alludes to the statement of Piorry in reference to the action of quinine, of which a single dose had the effect of reducing almost instantaneously the enlargement of the spleen which so generally accompanies ague; and then cites the following case, illustrative of similar effects produced by a large dose of ether given by himself:—

Henry Magee, a sailor, ætat. 31, who had been exposed to a great deal of wet in various ways, had, while at work one day about two months previous to his admission, suddenly felt a general lassitude, with dull boring pains in his loins. After being two or three hours in this state, shivering supervened, which lasted for the two succeeding hours. Since that period, he has had shivering fits almost every twenty-four hours, being pretty well during the intermissions. About a month before coming to the hospital, his abdomen became enlarged without previous pain or tenderness. On admission, December 2, 1844, he had shiverings almost every night, preceded by a feeling of creeping over his skin, a sense of lassitude and depression, and an inclination to stretch himself. The duration of the rigors was very irregular, sometimes continuing a quarter of an hour, at other times two or three hours; usually followed by sleep, during which there was copious perspiration. The abdomen was swollen to a considerable size, with a distinct feeling of fluctuation; no tenderness in the liver or spleen; whites of the eyes not discoloured; tongue clean; urine considerable in amount, and high-coloured. Ordered, on the 4th, a senna mixture, and the day after pills with half a grain of aloes and half a grain of calomel three times a-day.

9.—Abdomen thirty-five inches, with a good deal of tympanitis over it; spleen much increased in size, encroaching on the thorax. To take ten grains of quinine at night. At the morning visit at eight o'clock, Dr. Corrigan found that the usual rigor had been absent the night before, but had come on at this moment, and on examination he was enabled to trace out with Bennet's pleximeter the area occupied by the spleen, the information afforded by percussion being so distinct, that there was no difficulty or danger of mistake in marking the boundaries. The margin of the spleen having been several times traced out in this way, its area was thus marked on this surface, and was found to occupy a space measuring six inches in length and seven and a half inches in breadth. The rigor being still on him, he was given two drachms of ether with twenty drops of tinct. opii. Five minutes after the rigor had entirely disappeared, the pulse had come down from 120 to 96, skin got warm, and the spleen only measured six inches and three quarters by four inches and a half. The subsequent treatment consisted in the administration of a few ten-grain doses of quinine at bed time; no rigor took place from the time the dose of ether was given, and the fluid in the abdomen disappeared under the use of a solution of iodide of iron, taken three times a-day. The man was discharged on the 30th of December.

The following facts are, Dr. Corrigan observes, established by the foregoing case:—1. That the spleen can suddenly alter its volume; 2. That other agents as well as quinine can effect this sudden alteration of size; 3. A confirmation of an old observation, that a cure of the disease may be effected by other remedies as well as quinine. Here, he observes, the ether acted even better than the quinine, large doses of which failed to cut short the disease, having merely prolonged the interval and made the supervention of the attack later than usual; but the two drachms of ether with opium at once cut short the cold fit, and the attack never returned.

To a woman who laboured under tertian ague, Dr. Corrigan gave, in the intervals of the fits, ten-grain doses of quinine, under which she recovered. A singular result in this case, he observes, followed the administration of the first dose. In two minutes after there was a reduction in the size of the spleen, similar to the former case, but in an hour or two the organ regained its former bulk; in the afternoon of the same day, however, it had again diminished, and the patient gradually recovered.

M. Kelly, ætat. 32, a sailor, had been attacked with ague several times in the course of nine months previous to his admission on the 3rd of February, 1845, to the Whitworth Hospital.

4.—Had a fit of ague which lasted half an hour; during the fit there was considerable tenderness over the region of the spleen, and percussion showed it to be considerably enlarged. Skin cool and of a jaundiced hue; eyes also yellow. Spleen enlarged, occupying the space from the last rib to the crest of the ilium; tongue rough and furred in the centre; appetite bad; bowels regular; urine copious and high-coloured; sleeps badly at night; epigastrium tender on pressure.

A dose of ether was given to this man on the day after his admission in the cold stages, by a pupil who had seen its efficacy in the former case. The next day there was no fit, but the day after the attacks returned and continued. A pill of Pil. hydrarg. gr. ij, Calomel gr. j, Ext. taraxici gr. ij, Opii gr. $\frac{1}{4}$, was given three times a-day until the gums were touched, and under this treatment, directed against the local subacute inflammation of the liver, the cold fits shortened from about two hours' duration to twenty minutes. By the use of the ordinary treatment of quinine the spleen now considerably decreased in size, and the man was discharged on the 13th of April.

Dr. Corrigan observes, in reference to chronic enlargement of the spleen, independent of ague, that he has seen it occupy nearly the whole of the left side of the abdomen, remaining so for years without causing dropsy. He believes that considerable enlargement, where there is also induration, cannot be removed, having tried mercury, iodine, and quinine with no benefit, and has known counter irritation to be equally inefficacious in the hands of others. The actual cautery, he observes, is a remedy in constant use in India. He is of opinion that, in cases of this kind, attention to the general health is better than trying to act on the local disease; and that if the constitution be not tampered with, there will probably be little injurious effect for many years; but, as in all chronic cases, that circumstances may arise requiring interference. For the relief of the oppressed breathing, difficulty of lying down at night, and inability to walk much, which most persons of large spleen complain of, Dr. Corrigan recommends the use of small bleedings, to the amount of four ounces repeated two or three times, at intervals of two or three days. There seems in these cases, he observes, a great disposition to an accumulation of venous blood, as evidenced by the enlargement of the superficial veins over the body. The smallness of the pulse and coolness of the skin must not prevent the employment of the lancet; at the same time that large bleedings, which would depress the strength, must not be ventured on. The other means to be used to assist the bleedings must depend on the indications to be fulfilled.

M. Müller, of Berlin, has been appointed a Corresponding Member of the Académie des Sciences, Paris, in the room of M. Provencal, of Montpellier, deceased. The unsuccessful candidates were MM. Carus, of Dresden; Baer, of St Petersburg; Rathke of Küningsberg; Purkinje, Breslau; Valentin, of Berne; Della Chiaje, of Naples; Nordmann, of Odessa; Eschricht, of Copenhagen; and Newport, of London.

PROGRESS OF ENGLISH, ITALIAN, AND AMERICAN MEDICAL SCIENCE.

[The following are the only articles of interest to the profession in three numbers of the *Medical Gazette*.]

ALBUMINURIA.—Dr. C. J. B. Williams details, in the course of a clinical lecture, the principal features of several cases of albuminuria, which have terminated fatally under his care. The cases are five in number; three of the patients died in the course of a few hours after admission. One of these three died of pneumonia, another of delirium tremens, and the third of apoplexy. Of the other two, one died of pneumonia supervening on phthisis, together with albuminuria, and in the fifth there was very extensive organic disease of the heart complicating the albuminuria. In the cases of pneumonia, the inflammatory action affected both lungs. In the first of these, the patient was a young man of very intemperate habits, who, having been deprived of his accustomed stimulus, was seized with a kind of delirium or maniacal affection, in consequence of which, according to his own report, he spent several days running or walking about, taking refuge at night in some out-house without sufficient covering, and with very little nourishment. When admitted, as he presented evidences of double pneumonia, he was bled to twelve ounces, which produced faintness; some reaction took place, and he became delirious, dying the same evening in a state of great exhaustion. On examination of the body, nearly the whole of the right lung was found to be inflamed, in a state rapidly advancing towards hepatisation, and the left lung was affected considerably in the same way. There were several old tuberculous lesions at the upper part of both lungs, and at the apex of the left a cavity of the size of a hazel-nut. There were hemorrhagic spots in several parts of the lungs, showing not only inflammatory engorgement, but extensive extravasation of the blood from the vessels. The kidneys were found diseased, being affected with one of the forms of granular degeneration. The urine which was found in the bladder was ascertained to be albuminous. The post-mortem examination in the case of delirium tremens showed some congestion of the cerebrum, considerable effusion throughout the substance of that organ, with general softening and atrophy. The sensibility of the patient during life was diminished, but there was not any paralysis of motion. The man's kidneys were in the state of granular degeneration. It is also stated that there was a little urine in the *blood*—enough to exhibit the appearance of albumen. [This must be a careless misprint of blood for bladder.] The case of apoplexy was attended with complete insensibility, with more loss of power on the left side than on the right. On opening the skull there was found hemorrhage to an enormous amount, breaking, and forming a very large clot in the substance of the brain, over the whole extent of the right ventricle, and reaching into and quite filling both lateral ventricles; the septum lucidum was completely broken down, and the large clot communicated through the fourth ventricle even to the base of the brain and cerebellum, so that the whole of the central portion of the brain seemed to be occupied by this enormous clot of blood, which was so much matter added to the encephalon: hence the brain seemed too large for the skull, and projected a great deal when the cranium was removed. There was a great deal of blood also in the vessels of the dura mater. The blood-vessels of the brain generally were remarkably thin. The left kidney was very small and atrophied, and weighed only two ounces. The capsule was strongly adherent to the texture, and on being torn off drew many grains of cortical texture with it, interspersed with larger masses of opaque deposit. There was much fat in the pelvis and calices of the kidney, and its cortical substance was very much reduced. The right kidney was larger than usual, weighing seven ounces six drachms. Its capsule did not adhere; but the organ was much congested and coarse in texture, particularly at its lower part, and was mottled with a whitish deposit of soft consistence. The urine in the bladder was albuminous. Dr. Williams is of opinion that in the majority of cases of thundering apoplexy, where a large quantity of blood is effused on the brain, the affection is connected with granular degeneration of the kidneys. The next case is one of pneumonia complicating phthisis and albuminuria. On examining the body after death, there were adhesions at the apex of the left lung, and in the same part were some large clusters of grey tough consolidations; and some small masses of the same kind near the root of the lung. The lower half of this lung was in an engorged and softened state, between engorgement and hepatisation; almost sinking in water. At the apex of the right lung was old consolidation with puckering, and something like the remains of a cavity. A little yellow tuberculous matter could be detected there; but the chief mass was composed of a kind of dwindled grey tubercle, as if partially absorbed. The two lower thirds of the lung were in a state of soft hepatisation, when squeezed exuding a red jelly-like matter, and sinking in water. In the vicinity of the consolidations at the apex of the lungs, portions of the tissue were emphysematous. There were also some opaque patches on the outside of the heart; no other disease. Weight eight and a half ounces. Patches of opaque contractile deposit were found on both surfaces of the liver, and some appearance of interstitial deposit. Weight two pounds twelve ounces. The kidneys were rough and granular on surface; the removal of the capsule drew up many grains; texture coarse, and of a dirty brick colour. Weight of each kidney about five ounces. They were larger than usual, but not softer. The last case was one of morbus cordis, the complication of which with albuminuria caused Dr. Williams to give an unfavourable prognosis. He observes that all cases of morbus cordis, to the extent in which it occurred in this patient, are dangerous, but not so much so as is commonly supposed. Morbus cordis, in by far the greater number of instances, becomes complicated with other affections; and, as a general rule, singly it does not destroy the patient, though it may do so in extreme cases. It may, as a chronic disease, attain an enormous amount without destroying life, and, indeed, the tendency to produce that result is usually proportioned to the extent to which it interferes with the function and structure of other organs, more particularly with the lungs, the liver, and the kidneys, and the latter most of all. Now this fact is the more important, because it shows that, by removing or preventing these complications, we may avert the fatal termination for a considerable time. The ultimate result of heart-disease, where it increases very much, is to induce albuminuria. At first the albuminuria is a mere temporary or functional state, and it may be said to be induced by a great amount of congestion during the severe embarrassment of the circulation, caused by a transient aggravation of the heart-disease, and this may be carried off under proper treatment. It is where the urine becomes permanently and increasingly albuminous, and where, with the presence of albumen, there is a deficiency of the natural constituents of the urine, so that the excretory function of the gland is reduced, that the approach of the fatal termination of the heart-disease is announced. On the post-mortem examination of this case, the pericardium was very firmly adherent to the heart at every part, and to a large surface of the front walls of the chest. The lungs were pushed aside by the enlarged heart. The liver descended very nearly to the umbilicus. The right lung presented some opaque false membrane on the lower and middle lobes. It was moderately congested, but crepitant throughout, and felt of firmer texture than usual (hypertrophy). A well-defined apoplectic clot at the lateral portion of the lower lobe. Weight thirteen ounces and a half. Left lung small, weighing nine ounces and three-quarters. Lower lobe only moderately congested. An apoplectic clot in the lower part, firm, and very dark in colour, mottled with patches of paler opaque matter. The aortic valves were found to resist the passage of a strong current of water; they were small, but the calibre of the aorta also was small; some small vegetations attached to the corpora arantii, and adjoining free margin of the valves. Both laminæ of mitral valve considerably thickened and shortened, especially the posterior lamina, which was puckered into a mere ridge on the auriculo-ventricular ring. The tendinous cords were also shortened, and some of them were adherent. The valves on the right side were healthy. The heart was itself very much enlarged, weighing sixteen ounces and a half. The right kidney was mottled, but not in a high degree. The capsule raised granules only in parts. Cortical substance paler than usual. Weight four ounces and three-quarters. The left kidney was remarkably firm in texture, and the cortical substance was paler than that of the right. Weight four ounces and three-quarters. Both kidneys exhibited the appearance of cacoplastic deposit, and also a considerable amount of congestion. The liver also was much congested; it was of a dark red colour; and on cutting into it the branches of the hepatic vein were so large that many of them admitted the tip of the finger, and were full of blood. There was a considerable amount of pale deposit in the liver, mottling its structure, and this was observed to be accumulated especially around the portal veins. Some parts of the pale substance were stained with bile, and these masses were interspersed with portions of the ordinary texture of the liver. This organ weighed two pounds two ounces and a half, and when closely examined, presented numberless orange-coloured points, smaller than the acini, but still resembling them in form. Between and around these the tissue was of a fawn colour, and less opaque. Under the microscope the fawn-coloured deposit was found to be composed of numerous nucleated cells. The smaller central points contained much fewer cells, and more filamentous tissue. Dr. Williams next proceeds to account for the prevalence of albuminuria at the time these cases were admitted, from the changes in the weather. Changes of temperature, sudden transitions from cold to warm, from warm to cold, operate mainly by affecting the general circulation, by causing a great internal congestion, driving the blood from the surface, and thus in an undue degree taxing weak organs. There are a number of facts which bear on this point, in connection with albuminuria as a temporary disorder, or a permanent affection arising from congestion of the kidneys. In a subsequent lecture, Dr. Williams treats of cases of this complaint which did not prove fatal, even when accompanied by structural disease. The first case is that of a man, labouring under general dropsy and albuminuria for the second time, he having been cured five years previously of a similar attack. When first admitted, there was general dropsy and anasarca, and the urine was highly albuminous. He remained in the hospital three months, and when discharged he was free from dropsy, the strength and flesh in a great degree restored, and the urine had lost its albuminous impregnation. It was, however, of a lower specific gravity than usual. He remained well for two years, when he had a slight attack, of which he was soon cured. The second attack was, apparently, as severe as the first, and while in the hospital the man had an attack of sub-acute pleuritis. The dropsy was very obstinate, and long resisted the treatment by hydragogue purgatives, blisters to the loins, and diuretics, but at last yielded. The man was ultimately dismissed relieved He has, however, again been admitted into the hospital with general dropsy and albuminuria, and there can be but little doubt that the third attack will terminate fatally. The next case is that of a man, who was admitted with pneumonia, after drinking to excess. Exposure to cold, after the kidneys have been exhausted by the excitement of alcoholic drinks, is, Dr. Williams says, peculiarly trying to the function of the kidney. The man's urine was scanty and turbid, specific gravity 1·017, and it contained a great deal of albumen. The daily progress of the case showed a gradual increase of the specific gravity, and a corresponding decrease of the albumen in the urine. The man recovered perfectly. This appears to have been a case of quite temporary albuminuria, and to have occurred from the same cause as that which produced the inflammation in the chest, and such a cause as is known frequently to produce acute albuminuria. The next case was a slight attack of albuminuria occurring in an hysterical subject, after exposure to cold, and was soon cured by purgatives and a blister to the loins. In the next case, one of nephralgia with hæmaturia, combined with albuminuria, Dr. Williams suspected the

presence of a calculus in the kidney, or of some permanent structural disease, tending to the obstruction of the circulation through the kidney. The treatment adopted was calculated to remove congestion of the kidneys, and medicines which diminish the lithic deposit were also given. The urine continued albuminous when the man was dismissed, although he was in apparent health. The next case is one of acute dropsy with albuminuria, and was treated by cupping on the loins, diuretics, and hydragogue purgatives; and when convalescent, quinine with nitric acid was administered. The man was dismissed cured, but Dr. Williams thinks that there has been laid the foundation of a disease which may ultimately prove fatal sooner or later—sooner if he neglects precaution; sooner if he goes on in his habitual intoxication; sooner if his circumstances expose him to sudden transitions of temperature, or any other cause tending to an internal determination of blood, or continued congestion; sooner if his nutritive function should become impaired, so that there should be a tendency to increase the degenerative disease:—but later if these different causes are avoided, if he adopts regular diet, careful management, warm clothing, and other means of securing the proper regulation of the circulation, and a sufficient freedom in the functions of excretion. Next follows a case of valvular disease of the heart, with symptoms of low endocarditis and albuminuria, the patient suffering several relapses while in the hospital, but being ultimately dismissed, relieved as to the heart-disease, and apparently cured of the albuinuria. There was then scarcely any albumen in the urine, and the specific gravity was about natural. In the next case, the disease was complicated with a small amount of pulmonary affection, and a diseased condition of the uterus also complicated the case. The patient is still under treatment, and has already manifested some degree of improvement. The last case is that of a ricketty patient, labouring under albuminuria, consequent on the dropsy following scarlatina, and complicated by sub-acute pulmonic inflammation, with effusion into the chest, and enlargement of the spleen and kidneys. She was treated by blistering between the shoulders, the exhibition of squills, digitalis, and iodide of potassium internally, moderate purgation, and, afterwards, mild tonics. The pain which existed in the right loin was removed by cupping, and the patient was ultimately discharged without any apparent ailment.

Emphysema.—Mr. B. Phillips narrates a case of emphysema from fracture of the sixth and seventh ribs near the angles, in which air was effused in the neighbouring cellular tissue, the cavity of the chest not being implicated. He accounts for this by the presumed existence of old adhesions at the part, as, he says, under those circumstances, the air can more easily find its way into the cellular tissue, than through the false membrane into the cavity of the pleura.

Fracture of the Humerus.—Mr. B. Phillips describes a case of fracture of the humerus occurring from muscular action in a man who had long been labouring under rheumatic inflammation of the bone, by which it had been rendered fragile. Iodide of potassium and the compound decoction of sarsaparilla were exhibited internally, and, under their use, callus was formed, and the bone united. Mr. Phillips remarks, that it will be interesting to observe whether, if there be any return of rheumatism, the callus will give way.

Strangulated Hernia in the Inguinal Canal.—A man was admitted into the Westminster Hospital with symptoms of strangulated hernia. He had been ruptured six or seven years previously, but had not worn a truss for several months. There was a fulness of the upper part of the canal, and a distinct protrusion could be felt against the finger when the man coughed. Mr. Phillips operated the day after his admission. The incision extended from a little above the inner ring to a little below the external ring, and certainly at that time there was nothing to make it probable that there was much intestine in the canal. When the incision had passed through the aponeurosis of the external abdominal muscle, a tumour of the size of a hen's egg became at once apparent. The sac was found perfectly flaccid, and could be drawn down much below the gut; there was no fluid in it, but when the inner ring was enlarged, three or four ounces of fluid escaped from the abdomen. The intestine was dark in colour, a good deal congested, but had not lost its polish. Some symptoms of peritonitis followed, which were appropriately treated, and the man recovered.

Causes of Sudden Death.—An anonymous correspondent gives the following as the causes of sudden death:—In the head—rupture of the basilar artery; rupture of one of the other large arterial branches in the vicinity of the respiratory tract; apoplexy occurring in the pons varolii; sudden effusion of blood or pus into the lateral ventricles; general venous congestion of the brain and its membranes, especially in coincidence with cardiac and pulmonary obstructions. In the thorax:—right side of the heart—Rupture of the right cavities or pulmonary artery; inefficiency by rupture or ulceration of the pulmonary valves; sudden influx of blood to the right ventricle, or the occurrence of additional pulmonary obstruction, in any case where that cavity has become weakened from any cause: Left side of the heart—Rupture of the left auricle, instantaneous death; rupture of the left ventricle, generally in connection with fatty degeneration or thinning of the heart, or obstruction of its nutrient vessels: death is usually, but (from the cause mentioned in speaking of rupture of the right ventricle) not always instantaneous; rupture of the coronary arteries—immediate death. The coronary arteries have been found greatly obstructed or obliterated in cases of sudden death. Persons in whom the left ventricle is, from any cause, much weakened or dilated, especially where the aortic valves are inefficient, are liable to die suddenly, or to be seized with symptoms of thoracic oppression, which prove fatal in a few hours. Sudden rupture of the cords of the mitral valves may cause death within an hour in a diseased heart, but does not appear to be suddenly fatal when occurring in a healthy one Sudden death from rupture of the vena azygos is rare, but cases have been recorded by Morgagni and Dr. J. Flügel. Transverse rupture of all the coats of the aorta, or of an aneurism within the pericardium, is instantaneously fatal. Respiratory apparatus—Dr. Francis gives a case of purulent infiltration and œdema of the glottis, in which death took place within five minutes. Profuse arterial hemorrhage from the lungs may cause death, either by suffocation or by collapse. The bursting of an aneurism into the trachea, bronchus, or substance of the lungs, is generally fatal at the first or second gush. The sudden occurrence of a communication between an aneurism of the aorta and the pulmonary artery, auricles, superior cava, or other part of the cardiac apparatus, is liable to cause immediate collapse and distress, and death within a few hours; but sometimes dissolution occurs at a later period, and probably never instantaneously. Rupture of an aneurism into the pleura is followed by instant death. In the abdomen—In rupture or ulceration of the splenic or coronary artery into the stomach, sudden death from hæmatemesis may occur; but the time of death has varied in several cases, according to the size of the aperture and amount of the hemorrhage. Rupture of an aneurism of the abdominal aorta or other large vessel, into the peritoneal cavity, is followed by death within five minutes. Extravasation of feculent matter, bile, or other irritant, into the peritoneum, may produce death from collapse in from three to seven hours, or from inflammation in from eight hours to three days; but extravasations of this kind are not invariably fatal.

The Frequency of Cancer in the Two Sexes.—Mr. T. Wilkinson King says, of all females who die about forty-four years of age, nearly one-half have cancer; of males, one-eighth. Cancers, he says, increase in frequency from youth up to the forty-fourth year, and then decrease; but in males above sixty-five, one-fifth of all who die are cancerous.

Lead Palsy.—Mr. Pearl narrates several cases illustrative of the toxic effects of lead on the system. Its ingestion was owing to the use of water containing a certain proportion of carbonic acid which had passed through lead pipes, by which means it became charged with carbonate of lead.

Dislocation of the Sternal Extremity of the Clavicle backwards.—Mr. Brown had a case of this rare accident, which occurred from a fall in wrestling. The man had been thrown to, or rather *upon*, the left shoulder, so that this was forced forwards. The great force of the fall was assisted by the weight of the other wrestler coming down upon him. Instead of the clavicle giving way in its outer curvature, the sternal end of the bone was completely driven backwards. There was much pain, with some embarrassment of breathing. The limb was put up with the wedged-shaped pad in the axilla; the elbow, in order to be made to act as the lever, being fastened to the side by means of a roller passing alternately round the body, and over the right shoulder. Thus the elbow was supported, and the fore-arm fixed upon the breast, whereby the shoulder was kept back, in addition to the primary object being obtained, of confining the elbow to the side, and so making the pad effective as the fulcrum. The result of the case is not stated.

Discolouration of the Nails from the Internal Use of Nitrate of Silver.—From an experiment made by Dr. Madden, it would seem that this discolouration is not in the nail itself, but in the matrix beneath.

Perforation of the Cœcum.—A case of this kind is narrated from the practice of Mr. Cooper. The patient was a man sixty-four years of age, who had been ruptured for five or six years previously. He was admitted into the hospital with sickness, tympanitis, and constipation, accompanied by considerable restlessness. Scirrhous obstruction of the rectum was discovered by means of the flexible tube about five inches from the anus. The man, two days after his admission, was suddenly seized with violent pain in the abdomen, with great prostration, and he died early the next morning. Sectio cadaveris twenty-nine hours after death. The abdomen was enormously distended, but the external appearance of the rest of the body was that of a healthy man. Whilst opening the abdomen a quantity of very fetid gas escaped, and the parietes collapsed. Fæces were found spread over the surface of the peritoneum. A small portion of the small intestines were glued together by recently deposited lymph, and they were minutely injected. The large intestines were enormously distended, and their coats thin. In the cœcum there was found a perforation about the size of a shilling, and its peritoneal surface was congested and of a dark colour. Upon laying it open there was exposed a large oblong whitish slough, at one end of which was situated the perforation. The ileo-cœcal valve was healthy; nor was there any source of interruption to the passage of the contents of the small intestines through it. Upon removing and laying open the rectum, it was found contracted at its upper part for about two inches, with the coats thickened and indurated, and its mucous surface ulcerating and sloughy at that part. About three inches from the margin of the anus were one or two transverse folds of mucous membrane. The brain and thoracic viscera were not examined. There can be no doubt that the cœcum had been the contents of the inguinal hernia, and its nutrition deteriorated by its protrusion.

Rupture of the Bladder.—Mr. Spencer Wells describes two cases of rupture of the bladder, which terminated fatally. The first was a carpenter's mate, thirty years of age, who, while in a state of intoxication, fell out of his hammock, striking, as he supposed, against a stool. He complained soon after of severe pain above the pubes, considerable distention above the pubes and umbilicus, with great desire to void his urine, but inability to do so. The pulse was quick, small, and intermittent; skin cold; great pain and extreme tenderness on pressure above the pubes. A small quantity of urine was drawn off by the catheter, with partial relief; a hip-bath and a full opiate were afterwards employed. The symptoms increased in severity during the night; six ounces of nearly pure blood were drawn off the following morning by the catheter. A few hours afterwards he was admitted into the Malta hospital. The countenance was then very anxious and contracted, the surface cold, and covered by a clammy perspiration. There was also circumscribed distension, about the size of a cricket-ball, between the pubes and umbilicus, and such excessive tenderness that he shrunk from the slightest touch in that situation. A catheter was passed, when between nine and ten ounces of nearly pure blood flowed.

On examination of the bladder by the rectum it gave the sensation of a hard solid body pressing towards the concavity of the sacrum. On rotating the catheter, so as to cause motion of its beak, a sensation was felt as if it were pressing against some elastic substance. He was at this time troubled very much with vomiting. Opiates, leeching, and turpentine enemata were had recourse to, but peritonitis set in soon after, and the man died a hundred and twenty-two hours after the accident. The body was examined twelve hours after death. On dividing the parietes of the abdomen, the whole of the tissues beneath the superficial fascia were found of a reddish-black colour, softened, gangrenous, and exuding copiously, on pressure of the knife, a bloody serum, having a urinous odour. A catheter was passed through the urethra into the bladder, when its point immediately became visible in a large cavity, which was bounded superiorly by the reflections of the peritoneum from the anterior surface of the rectum, and the posterior and superior surfaces of the bladder. The peritoneum being pushed upwards had left a large cavity, filled with urine and coagulated blood; at the bottom of which was the bladder, quite contracted, with a rent in its anterior surface about an inch and a half in length. The edges of this opening were red, hard, and rounded. The whole of the cellular tissue surrounding the bladder, the muscles around the pelvic cavity, and the superficial abdominal muscles, were all softened and gangrenous, and permeated by a urinous fluid. The peritoneum exhibited the usual marks of intense inflammation, but was perfectly entire. Very little serum was effused into its cavity, but the intestines were adherent to each other by the recent effusion of coagulable lymph. The kidneys presented no sign of disease. No mark of any blow could be discovered upon the integuments of the abdomen. The second case, which was caused by a fall across the loins on a chain cable, presented symptoms of cystitis, with hemorrhage into the bladder, supposed to originate in the kidneys. Peritonitis set in soon after, and the case terminated fatally in a hundred and ninety-five hours after the fall. On examination of the body after death, the thoracic viscera were found to be healthy, also the liver, spleen, and stomach, and the intestines, except their peritoneal coat. The right kidney presented no signs of inflammatory action, but appeared to have been the seat of hemorrhage, as several small coagula projected from the calices and infundibula. The same state was observed in the left kidney, but in a less degree. The whole of the moveable intestines were displaced from the lower part of the abdomen, and pushed upwards to a level with the umbilicus. They were here united together, and to the walls of the abdomen, by lymph recently effused upon the surface of the peritoneum. The cavity formed by these peritoneal adhesions, and by the reflections of the membrane over the pelvic viscera, was distended by a clear bloody serum, not urinous in its odour. This fluid was removed by a sponge, when the bladder appeared much enlarged, and its postero-inferior surface was dark-coloured and gangrenous in appearance, the peritoneum being implicated in the gangrene. On injecting the bladder *in situ* through a catheter passed by the urethra, the fluid exuded through this dark gangrenous portion into the peritoneal cavity. The whole of the cellular tissue surrounding the bladder, and connecting it with the walls of the pelvis, was exceedingly thickened by urinary infiltration, and the results of inflammatory action. It had a fetid ammoniacal odour, and was dark brown in colour. The mucous membrane was excessively inflamed, raised into highly vascular rugæ, and a perforation upwards of an inch in length was found on the anterior surface, a little to the right side, and just below the reflection of the peritoneum. Its edges were red, hard, and turgid. The muscular coat was very distinct, and of a light slate colour. In this case the operation of opening the bladder was proposed, but rejected on account of the peritoneal complication. With regard to the diagnosis of similar cases, if immediately after any accident likely to injure the bladder, severe pain follows in the hypogastric region, with passage of blood or bloody urine by the catheter; if more than a very small quantity of blood is never voided at one time, nor drawn off by the catheter; if a peculiar sensation of pressure against the point of the catheter be felt, and if these symptoms be unaccompanied by the severe prostration of strength and depression of pulse, which always follow peritoneal perforation, rupture of the bladder external to the peritoneum may fairly be inferred, and the treatment founded on the inference. The most rational treatment would appear to be to make a free opening through the perineum and deep pelvic fascia, in order to allow a free exit to the urine infiltrated through the pelvic cellular tissue, and, if necessary, a counter opening above the pubes. The case would then be no worse than one of wound of the bladder with extravasation, and by keeping an elastic catheter constantly in the bladder, further infiltration might be to a great degree avoided. Under this treatment, with opium, and the necessary means for combating peritonitis, if it arise, Mr. Wells would not consider the case by any means so hopeless as one in which the peritoneal cavity was opened.

Lithotomy.—Two cases of lithotomy are reported from the practice of Mr. Key, in which considerable difficulty was experienced in seizing the stone, from its position at the fundus of the bladder, and which was only overcome by pressure made externally over the fundus, when the calculus dropped between the blades of the forceps. Mr. Key in some clinical remarks on these cases, observed that a calculus usually lies free in the bladder as long as the mucous coat of the organ preserves its healthy condition. The oxalate, urate, and even the phosphatic stones, are found in the base of the bladder until the surface of the membrane becomes villous from inflammation, and its secretion becomes alkaline and viscous. The bladder, inflamed and irritated by the stone, contracts upon it with more force, and secretes an abundance of alkaline mucus, the phosphatic salts of which crystallize on the surface of the stone, and make it adhere often with considerable tenacity to the surface of the organ. This fixed state of a calculus is not only an evil in itself, adding much to the difficulty of an operation, but is met with in patients whose bladders have suffered much from irritation of the stone, and who are generally least able to bear up against the effects of a difficult and protracted operation. The part of the bladder usually occupied by a calculus under these circumstances is the fundus, which retains the stone with tenacity, while the lower part of the organ receives the urine as it passes from the ureters; in sounding such a bladder, the calculus is felt either on the concave surface of the instrument, or by withdrawing it towards the pubes—a circumstance that always portends some difficulty in seizing it after the bladder is opened. It has happened more than once that a patient has been removed from the operating table with the stone remaining in the bladder, after long and continued efforts made in vain to seize it; and the failure has arisen, not from the extraordinary size of the calculus, but from its peculiar position. The forceps, at first, though opened to their full extent, obtain but a very slight hold of the stone; the extremity of it only is seized, and it soon escapes from the grasp of the operator. Repeated attempts are made to gain a firmer hold of it, and at each attempt the stone is pushed further from the opening, until the forceps are obliged to be buried nearly to the handles before the stone can be felt. It is in the retreat of the stone before the forceps that the difficulty of seizing it lies. The stone, instead of retreating in a direct line from the opening into the bladder, ascends behind the pubes, where the forceps cannot without assistance, reach it, much less grasp it. The handle of the forceps, though depressed as much as the wound will allow, cannot carry the blades high enough to reach the stone, and it requires very firm pressure on the lower part of the abdomen to depress the stone sufficiently to enable the forceps to seize it.

Abdominal Presentation.—Dr. Reid mentions a case of presentation of the abdomen (a very rare occurrence), in which the insertion of the funis in the abdomen was distinctly ascertained at a short distance from the os uteri. It was converted into a footling case without much difficulty.

Spontaneous Double Expulsion.—Dr. Reid mentions a case of twins, in which the second child was expelled double. Both children were living three weeks afterwards.

NOTICES TO CORRESPONDENTS.

A Handsome Portfolio *for holding the* "Medical Times"—*very desirable to those who would keep the numbers clean for binding, and easy of reference—may be had, by order of any Bookseller, or at the Office, price 5s. An allowance is made to the trade.*

☞ ☞.—*Several subscribers, in arrears, are requested to forward immediately the amount of their accounts, in order that their names may not be placed in our list of defaulters.*

☞ Defaulters.—*We regret to announce that Mr. J. Selkirk, of Sanchie, by Alloa, North Britain; and Mr. F. Clarke, late of Ballyconnell, Ireland, can receive from us no more Nos. of the Medical Times.* We cannot afford *to send journals on their system of non-payment. We understand that Mr. F. Clarke has recently quitted Ireland for America, where we hope this notice may meet his eye.*

J. G. F., Brentford.—*A new arrangement of the elementary bodies takes place. Acid properties are obliterated, but as probably a resinous body is formed, it would not be in accordance with chemical nomenclature to call it a sulphate of turpentine.*

Galen *sends us the following queries:—In what number of your paper will I find the following recipes:—" Le Rob de Laffecteur" (sudorific), " Acidulated Kali" (febrifuge). Would you be kind enough to search Cooley's last Cyclopædia of Practical Recipes, for the ingredients or recipe of Green's Medicated Soap (patent medicine)?—We presume our correspondent supposes time hangs heavily on our hands, and is accordingly willing to afford us a little amusing employment. We are compelled to undeceive him, and regret to say we have* not *time to attend to his request.*

E. B., Crewkerne.—*We must beg to refer our correspondent to the "Students' Number of the Medical Times," which will be published on the 26th of September, and will contain all the requisite information.*

Anglo-Irishman, *who sends us half-a-guinea as a donation to the Subscription Fund, but who will* not *subscribe to a prize endowment, is informed that we are unable to alter our intention respecting the allocation of subscriptions received. Unless we hear from him to the contrary, we shall place the sum to our correspondent's credit, in advance for the ensuing year. We cannot but be gratified at the kind feeling displayed by Anglo-Irishman in his highly flattering letter.*

E. K.—*We should say that, under present circumstances, it is not* practically *necessary.*

We must refer Old Man *to the "Medical Guide and Almanac, for* 1845."

A Constant Subscriber.—*Both the gentlemen named are examiners in medicine to the University of London.*

A Student, Shaftesbury.—*The Winter Session at Guy's and Bartholomew's Hospitals commences on Wednesday, October* 1.

J. H. G. W., Hoxton.—*We recommend our correspondent to break himself of his bad habit with all convenient speed. We have no doubt that, the excitement being removed, the effect will soon disappear. J. H. G. W. cannot persist in his present habits without serious injury to his health.*

We regret that Dr. Orpen *should not have received the numbers he sent for. They were posted in London safely, and the blame must be laid with the post-office. They were again sent on the 9th instant.*

Gentlemen connected with medical schools are particularly requested to forward immediately their prospectuses to the Medical Times Office, in order that they may appear in our Students' Number, *of 26th instant.*

On the 21st of June, 1845, we received a letter, signed James D. Protheroe, Surgeon, Medhurst. We gave a short abstract of part of the contents of his letter; but on writing to the address given, find our letter returned through the Dead-Letter Office. Can Mr. Protheroe, or some correspondent in Medhurst, throw any light on this subject for us?

Alpha.—*The session of the University of Edinburgh commences in November.*

Other correspondents next week.

The MEDICAL TIMES is the only Medical Journal published at its own Office, and which is free from the control of all Booksellers and Publishers. Gentlemen may procure it by an order on any Newsman or Bookseller, or it will be sent direct from the Office of the Medical Times to Annual Subscribers sending One Guinea IN ADVANCE, which will free them for twelve months. Half-Yearly Subscription, 13s.; Quarterly, 6s. 6d. The Pharmaceutical Number is published once a month, as an extra number; the subscription is 6s. per annum. No number of the Medical Times can be forwarded, except to gentlemen paying in advance.

THE MEDICAL TIMES.

SATURDAY, SEPTEMBER 13TH, 1845.

Orandum est, ut sit mens sana in corpore sano.—JUVENAL.

IN a country whose pre-eminent greatness depends so much on that industry which *creates* for commerce its due *pabulum*, viz.:—exchangeable materials -the diseases to which artizans are subject acquire an especial interest. While ruminating or studying in a luxurious ease, unknown even to a Sardanapalus or a Darius, there is the pleasurable sorrow of a contrast, mingled with the ennobling solace of a duty, in reflecting on the morbid results of that ill-appreciated activity which contributes so much to, and shares so little, in the happiness of civilised society. There can be no more pleasing office in the brotherhood of man, than that of mutually aiding to soften the primal curse of our race, labour, into a blessing; and if, by some stern necessity of the active, and perhaps not too perfectly managed, times we live in, a great portion of our skilled labourers must be subjected not only to toils protracted and burdensome, but to toils constantly assaulting, by morbid agencies, the very organism itself; if—odd paradox!—human beings catering to our enjoyments must be compelled by the progress of society to sacrifice, slowly but surely, one portion of their lives to win subsistence for the rest—then, we say, it is especially becoming in us, who profit by their self-nocent industry, to endeavour to return in some other kind our obligations, so as to make our luxuries come to us as costless as possible to our brethren, and benevolently meeting the woes of toil-worn necessity by the good offices of wealthy ease, adjust to some fairer proportions Nature's disordered balance of happiness.

In the vast process of social amelioration—for vast it is considered as a need on one side and a *duty on the other*—the Medical Profession forms the great active engine. Under all circumstances, our aid in mitigating the evil is called into unceasing play; and were social remedies and evils in anything like due proportion, were there any organisation to call out and adopt latent supplies to meet obvious and palpable wants, our share in the work of benevolence would be greater, our place in the station of honour higher. But as it is, we soothe many an hour's agony to wretches who, without our solace, would know none. The word of kindness, too rarely heard from the luckier of their kin, they have from us always—the prompt relief from pressing penury often—the medicament of health not unfrequently. Without a witness, we stoop to them; in the dark, our purses open to them; almost unconsciously we live to save them. Daily, in thousands and tens of thousands of cases, does our Profession act to injured, wounded, and ill-used Society the good Samaritan. Our actual exertions by the bed-side of the sufferer would, however, be the least of our services if there were those in high power who would seek in our experience, lessons "to teach the wretched how to rise." Much do we to *cure*, infinitely more with watchful governance and national aid could we do to *prevent* human misery. Seeing sufferings, it is as much our place to trace as to remedy them; and when, by our labours, the causes are detected, it would be well indeed if there were those in power whose especial office it would be to see to their mitigation. In any case there is much of utility in laying bare the mysteries of diseases lurking unseen by Government among some of the most useful and profitable of our fellow subjects; and, bringing in our humble contribution, we propose in this, and two or three succeeding articles, to touch on the diseases to which the workmen in lead mines are more especially subject.

These labourers are exposed to a multitude of agencies—some inseparable from the nature of their occupation, others arising from, or at least aggravated by, their ignorance—which deteriorate the system and *predispose* to disease, as well as to numerous agencies, which act as direct *excitants* on organs weakened by previous mismanagement.

It is, perhaps, unknown to many of our readers, that miners are peculiarly prone to intermarriage, and also to very early marriage. A very intelligent correspondent, Mr. William Armstrong, who has lately addressed a communication to us on the subject, and to whom we owe most of the facts on which these articles are based, accounts for this by stating, that as lead mines are always found in mountainous districts, and the miners live generally in the valleys, the people of one vale, or district, are often at a considerable distance from any other. This isolated state of communities is believed a cause of frequent intermarriages. Certain it is that intermarriages, are frequent and that is is a fertile source of degenerate offspring. But not content with this, the miner, with the true improvidence of ignorance, adds another source of evil—that of *early* marriage—marriage at a period when the whole *vis* of the constitution is requisite for the consolidation of the frame. How can we, from such parents, expect strong and healthy children? Not only do the parents suffer in their own persons for their imprudence, but they bequeath suffering as an inheritance to their unfortunate offspring. Add to this, the father's confinement in a close atmosphere, where the sun's rays never penetrate—his bodily labour and insufficient diet, of which we shall speak presently—and what result are we to expect? That infants are weak and puny—that they suffer from strumous diseases as children, and that as adults they fall victims, on slight exciting causes, to the scourge of our nation—tubercular phthisis.

Here, then, we have a being brought into the world to undergo a daily toil in an unhealthy situation, the atmosphere impregnated with particles of an irritating nature, with an hereditary constitution of the kind least fitted to withstand disease. But the first eighteen years of this individual's life are exempt from the exciting causes to which he is afterwards exposed. During this period he is engaged, at least in the case of the London Lead Mining Company's labourers, in washing the ores at the mouth of the pit, an occupation of a comparatively healthful and invigorating nature. From this short respite much is gained. At the period of his first descending into the deleterious atmosphere of the mine, growth is in some degree complete, at all events in the majority of instances; and if the bones are not firmly consolidated, and the limbs have not attained their full vigour, it must be evident that considerable progress towards this point has been made. The youth, also, by his employment in the open air, has had the full benefit of the sun's influence during a period when it is most necessary, and his system has obtained, during its greatest need, a due supply of healthy blood. Some benefit is to be expected from this mode of early life; and we find accordingly, by reference to Dr. Holland's tables, that whilst the greatest mortality among a class of men (the Sheffield grinders) exposed from boyhood to the same causes in an aggravated degree, which affect the miner at a later period, occurs between the ages of twenty and thirty, in the miner the greatest number of deaths occurs between thirty and forty-five.

Arrived at the age of eighteen, the labourer descends into the mine, and now he is subjected to several influences of importance predisposing to disease, to which he has not been previously so much exposed. The first of these for our consideration is *want of cleanliness*. The miners, partly from apathy, and partly from ignorance, never practise ablution. Working, as they do, in an atmosphere loaded with particles of fine dust, unless frequent baths be obtained, the surface not only of the exposed parts, but of the whole body, soon becomes covered with a kind of crust, in many cases so thick that the cutaneous texture is not visible in any situation. The miners believe that this crust renders them less liable to cold and to the injurious influences by which they are surrounded, and in consequence, instead of practising rigid cleanliness, rather preserve the crust. The result of this is naturally to throw the mass, which ought to be excreted by cutaneous transpiration, on the only other channel open to receive it, and thus to impose on the lungs, already badly able to perform their own functions, the extra duty of providing for the deficient cutaneous action.

We now proceed shortly to consider another predisposing cause of disease—deficiency of diet—as it affects miners. Our correspondent before alluded to—an observant and acute practitioner residing in the very centre of the lead-mining districts, whose opportunities of observation are unquestionable—states, that after a young man has entered the mine, one of the first things that demands attention is his "crowdie" diet. It is a matter of astonishment to all who know the miners' habits, how any man can, on such insufficient food, perform the daily arduous toil that he is exposed to. The small quantity of animal food consumed is indeed incredible. "Many of the miners," says our correspondent, "reside at a considerable distance from their place of labour, and consequently leave their homes on Monday, carrying their week's provisions, consisting of a small piece of bacon, some potatoes, brown bread, milk, tea, and coffee, and a little oatmeal, in a wallet; they remain at the mine during their period of labour, and sleep in a 'shop' built for them. Their diet consists chiefly of tea or coffee, and bread, with the exception of the morning meal, composed of 'crowdie' or oatmeal, on which boiling water has been poured."

The point that strikes us most forcibly here is the almost entire absence of animal food; for surely the small portion of bacon does not deserve to be ranked as a meal of flesh. We are fully aware that the quantities of meat consumed in the substantial fare of the middle classes are more than superfluous—positively injurious; but there are many and vast steps between the two extremes of

the daily bill of fare. The necessity of animal food in our climate is now well recognised, and more especially is it needful when called for by bodily labour. The miner's diet, even if continued daily for a lengthened period, in a person unexposed to exertion, must tend to weaken the constitution; much more, then, must it be hurtful to men who, in addition to extreme fatigue, are surrounded by so many deleterious agencies. The miners are accordingly subject to habitual constipation, dyspepsia, and a constant and distressing flatulence—causes sufficient to debilitate an iron frame: what effect must they then produce on one already predisposed to disease by nature? In another article on this subject we propose to consider the more immediate or exciting causes of disease to which miners are exposed, and subsequently to make a few remarks on the diseases as they actually occur, with the hygienic means most suitable to their prevention.

Divide et impera.

The "odium medicum" reigns nowhere so strongly, or so enduringly, as in Carlisle. All that is hateful, all that is evil, all that is unfortunate in medical dissensions, grows there in prolific rankness.

> Fy on't! O fy! 'tis an unweeded garden
> That grows to seed!

The Cumberland Infirmary, and the system of its medical appointments, have been, we believe, the "fons et origo" of this enormous evil. Some strong, and, we can hardly doubt, *reasonable* objections were felt against the manner in which it was arranged that the surgeons and physicians of that institution should be chosen. The principal medical men confederated to secure a system more satisfactory. The governors of the Infirmary became, however, as unyielding as the medical union showed themselves determined, and, for a time, it was in doubt whether the Infirmary would be able to muster a medical staff. The refractory governors, however, held the strong ground; the well-known dissensions of the medical profession were in their favour, and they had little difficulty in manning their hospital with a physician out of the ranks of the residents, Dr. Barnes, and with a surgeon, Mr. Page, from some distant locality. As might be expected, the defeat did not soothe the hostility, nor disconcert the union of the medical men leagued against the governors' system; the combination for mutual protection, defeated through treason in its own ranks, now showed some of the characteristics of an internecine feud, and the ill-feeling against Dr. Barnes and Mr. Page got vent in ways we need not now describe, but an illustrative instance of which was shown in the inquest on an old man, whose death was attributed to the ill-treatment he had received in the Infirmary.

Within the last few weeks Dr. Barnes, whose skill was in this unfortunate case brought in question, announced his intention to resign his appointment; about which time, or a little before, Dr. Goodfellow, a London physician, was found canvassing Carlisle for the successorship. He was speedily followed by two other candidates, residents of the town—Drs. Atkinson and Taineswood, who were in some slight degree, it would appear, identified with the previous insurrectionary movement, but who, on the present occasion, felt it not improper to put in the offer of their adhesion to the "existing order of things." The medical junto, if deserted, were not disheartened, and feeling that the drama of the hour would be a sad, mutilated performance, if they—the true *dramatis personæ*—were omitted in it, came, late it is true, on the boards with the following manifesto—at once the prologue, play, and epilogue of their performance:—

"September, 2nd, 1845.

"We, the undersigned, are still ready to give our professional services, as physicians and surgeons respectively, to the Cumberland Infirmary, on the condition that a fixed number of physicians and surgeons be taken in rotation, for six or twelve months each, as the Governors may determine; that in cases of difficulty the whole medical staff may be called in if necessary; that in case of absence, any other of the staff shall act; and that there be no paid medical officer except the House Surgeon.

(Signed) "Richard Jones, M.D.
"Joseph Cartmell, M.D.
"John Hodson, Surgeon.
"Francis W. Kerr, Surgeon.
"Thomas Elliot, Surgeon.
"John Mortimer, Surgeon.
"Peter Linton, Surgeon.
"Edward Bowman, Surgeon."

By the day of election it was very visible that Dr. Goodfellow was to have everything his own way. The chairman of the charity, the Bishop of Carlisle, brought more proxies in his pocket than sufficed to carry the election; and though against so formidable an antagonist, Dr. Tinneswood had the advantage of Dr. Atkinson's resignation and warmest support, he was defeated by a majority of fifty-four out of one hundred and fifty-two votes.

One circumstance of the election is worthy record: Dr. Barnes's resignation was coincident with Dr. Goodfellow's appearance as a candidate; it was understood that there was a very intimate relationship between the two circumstances—yet Dr. Barnes was the sturdiest opponent Dr. Goodfellow met with on the day of election! How was this? Dr. Barnes protested it was because he had discovered that Dr. Goodfellow was not allowed private practice while a resident medical officer to the Fever Hospital; and that the post itself was not as honourable as it should be. On examination, however, it appeared that Dr. G. was allowed private medical practice; and had practised during twelve years; and that Dr. Barnes had been frequently, but unsuccessfully, in treaty with him for a partnership in practice, and this while the canvass for the Carlisle appointment was going on!

And now for a word on the medical ethics of the Carlisle medico-civil war. As between the candidates, Drs. Goodfellow and Tinneswood, no single topic offers itself for the medical censor. Both are respectable and accomplished physicians; the one enjoying a fair provincial, the other a fair metropolitan repute, and, as far as the Profession is concerned, it is of no earthly moment whether *one* was non-resident, or both, or neither. The Carlisle Governors with their bustling bishop (whose conduct on this occasion proved him the sort of person one would have as a friend), in showing us that Carlisle physicians—deservedly or undeservedly—have no honour in their own country, and by brightening *our* escutcheon and tarnishing *their* own, acted—as they can prove *perhaps*—on good and sufficient grounds. At all events, it is not a matter on which we or the Profession have anything to do, except the ground on examination, should turn out to be that illicit kind of private, personal influence, which makes good scientific appointments to our public offices a mere matter of chance or personal caprice.

Between the two candidates and the Carlisle Medical men—between the supplicants for the Infirmary appointments and the Profession—there is another, and far more serious question opened that deserves our best consideration. The Medical Profession is the depository of its own honour, the conservator of its own privileges, and has the right, as far as justice sanctions, and the law of society allows, to determine under what conditions, in what manner, and to what extent, it will extend its services to the public. It is of the first consequence to society, as well as to ourselves, that we should prescribe and enforce on ourselves, as an aggregate public body, a career of honourable and worthy action. If we, or any profession, abandon the high duty of self-government, and indulge in all the lawlessness the strict letter of the law will concede us, we should be an anarchical faction in the commonwealth, degraded by trade conflicts into vulgarity and demoralisation, and sink, from a corps of gentlemen honourably serving our fellow-citizens (the noblest institution a civilised country can offer), into an irregular band of venal pettifoggers, extracting a miserable existence from the aggravation of social sufferings. We must, then, be privileged, as a general rule, to lay down our own code of internal government to our own body; and to fix the loss of such privileges as lie at our mutual disposal for the penalty of breaking our regulations. We are a voluntary incorporation for mutual good fellowship. A dissentient, to serve a private interest, is free to infringe the regulations made by us for the common weal, if he please; but if he do, so are we free to exclude him from the benefits and comforts of our mutual brotherhood. He is a person willing to participate of the advantages the individual sacrifices of the other members may bring to the whole body; yet ready not only *not* to yield a return, but to compromise its interests for a selfish end the moment the opportunity offers. In proportion as the general system is useful to society and honourable to the Profession, in that proportion stands disgraced and dishonoured the dissentient who places it in jeopardy for a small private interest.

With these views, therefore, we can have no hesitation in saying that the medical men of Carlisle who, uniting for a good professional object, refused to acquiesce in those regulations, laid down for them by laymen, which they believed incompatible with the interests of their science and the maintenance of good professional feeling, deserved well of their order, and should have been supported by the whole muster-roll of their brethren. It has been said of Irishmen—"Find me one, and I will find you another ready to cut his throat." If the same could not be said of medical men, Carlisle governors and Poor Law Commissioners would never have had to boast of their triumphs over the "doctors!" We must return to this subject.

Apothecaries' Hall.—Gentlemen admitted Licentiates on the 4th of September, 1845:—John Eardley, Thomas John Kent.

By a recent garrison order, the practice of Mesmerism as a remedial agent has been forbidden to the medical officers of the troops stationed at Gibraltar.

University of London.—M. B., First Examination, 1845, for Honour.—*Anatomy and Physiology:* William H. Ransom, University College (exhibition and gold medal); Thomas H. Huxley, Charing-cross Hospital (gold medal); William Brinton, King's College; John Reid, King's College; Walter Johnson, Guy's Hospital. *Chemistry:* William H. Ransom, University College (exhibition and gold medal); Cornelius W. Randell, University College (gold medal); Walter Johnson, Guy's Hospital; John Reid, King's College; William Brinton, King's College; Thomas H. Huxley, Charing-cross Hospital; John Climenson Day, London Hospital. *Materia Medica and Pharmaceutical Chemistry:* William Brinton, King's College (exhibition and gold medal); Walter Johnson, Guy's Hospital (gold medal); John Climenson Day, London Hospital; William H. Ransom, University College; John Reid, King's College.

THE UNIVERSITY OF EDINBURGH AS A MEDICAL SCHOOL IN 1845.

By Robert Lewins, M.D. &c.

(Continued from page 417.)

In the discharge of my duty as the humble, but devoted, champion of the fair fame of my *Alma Mater*, grievously aspersed by O. P. Q., the proceedings connected with the election of the present professor of midwifery in the University of Edinburgh, and a consideration of his merits, must now occupy our attention.

On the resignation of Dr. Hamilton, a short time before his death, several individuals started as candidates for the vacant chair, amongst whom were Dr. Lee, of London; Dr. Thatcher, and Dr. Campbell, who had long reputably taught midwifery at Edinburgh; Dr. Evory Kennedy, a physician in the prime of life, who had been four years assistant, and six years master, of the Dublin Lying-in Hospital, and who had been for a considerable time a lecturer on midwifery in the Irish metropolis; and Dr. Simpson, on whose head twenty-eight summers' suns had only shone, who had at the period referred to just finished his third course as an Edinburgh "extra-academical" lecturer on midwifery and on the diseases of women and children. Several minor obstetrical stars besides were candidates, the effulgence of whose rays may not, as yet, have penetrated the recesses of 49, Essex-street, nor reached any other source from whence issues light to illume the darkness of the medical horizon.

It soon became evident that the grand contest for the Edinburgh midwifery chair would be between Drs. Kennedy and Simpson, accordingly all the other aspirants retired from the field. Until the very last minute on the day of election, when it was ascertained that the junior candidate had carried it by a singe vote, the result remained quite uncertain. It is an interesting fact in the history of the University of Edinburgh, that many of the most distinguished of her professors were appointed when young men. Dr. Monro *primus*, at the age of 22 years; Dr. Monro *secundus*, at the age of 21; Dr. James Gregory, at the age of 23; Dugald Stewart, at the age of 21; Colin Maclauren, the eminent mathematician, was appointed to the mathematical chair at the very early age of 19! Forbes, the present distinguished porfessor of natural philosophy, at the age of 25; Dr. Christison, at the age of 22; Dr. Alison, if my memory in regard to the precise date of his appointment be accurate, must have been a professor before he was 30 years of age; Dr. Simpson was seated in the midwifery chair at the early age of 28; and the late Dr. Hamilton must have occupied it about the same age.

Particular circumstances made me well acquainted with the conduct of the electors upon the occasion under consideration; and I feel it due to the town council of 1840, to mention that, as patrons of the midwifery chair, they performed their duty in a very exemplary manner. And their deportment afforded conclusive proof of the utter groundlessness of O. P. Q.'s ungenerous accusation as to the corrupt and degraded condition of those in whom is vested the patronage of eight of the medical chairs in the University of Edinburgh. "Local influence" was, upon the occasion alluded to, employed actively and honestly, but unavailingly, in behalf of a talented *stranger*. English, Irish, and continental recommendations, however, in favour of an Edinburgh candidate, prevailed!—affording in the case before us, as in Dr. Traill's, a refutation of the assertion of O. P. Q., in regard to the manner in which professional appointments are made at Edinburgh.

The candidates for the midwifery chair were both men of rare talent and of European reputation. It was beyond the possibility of doubt, that the interests of the pupils of the Medical School of Edinburgh would be safe with either; but it was supposed by a party well-qualified to judge, and influenced by public considerations entirely, that Dr. Kennedy's age and greater experience entitled him to a preference. The individuals to whom I allude, aware that the midwifery professor has daily other duties of a difficult and delicate nature to perform besides teaching the principles of the obstetric art, were of opinion, that whoever fills the midwifery chair should be a man in whom, from his age and practical experience, the public and the profession will naturally confide, in cases of difficulty and danger, unhappily of too frequent occurrence.[1]

It fell to my lot to make a comparative estimate of the merits of the candidates, in reviewing the testimonials they presented—an invidious duty, which was performed, I believe, to the satisfaction of both Dr. Kennedy, and Dr. Simpson—certainly to that of their respective friends. In performing it, whilst justice was done to the splendid talents and rare attainments of the latter, and my meed of praise cordially and liberally bestowed on his extraordinary abilities, I said that, in my humble judgment, every thing considered, the very slight turn of the delicately-poised balance was in favour of his Irish opponent, who, as already stated, however, lost his election by a single vote. Dr. Kennedy, nevertheless, departed from the field of competition with untarnished fame.

But to return to Dr. Simpson's qualifications. As a student, he was one of the most industrious of his day. His superior talents, as has been the case with many of the shining lights of our profession, first became publicly apparent at the weekly meetings of the Royal Medical Society, of which he was for several winters a leading member, and in 1835 the first president.[2] But, I believe, the first occasion on which Dr. Simpson gave special public promise of distinguishing himself as an obstetrician (a circumstance of which he is himself, perhaps, not aware), was on delivering a lecture, *de fluxu catemenia*, in the year 1836, for the late Dr. Mackintosh, who taught midwifery at Edinburgh on the outside of the university walls. Dr. Mackintosh, from that day, predicted that Simpson was destined to be an extraordinary man as an obstetrical practitioner and teacher—a prediction which was, ere long, fully verified.

At an early period of life, Dr. Simpson's talents attracted the notice of Dr. Thomson, the learned and remarkable professor of pathology (than whom there is no better judge of professional talent), and was much employed by him as an assistant in the prosecution of his literary and scientific pursuits. Dr. Thomson's declining years rendering him unfit for the discharge of his academical duties, he entrusted Dr. Simpson with the important charge of conducting the pathological course of lectures during the session 1837-8, who did so with brilliant *éclat*.

Before the death of Dr. Hamilton, Dr. Simpson had displayed extraordinary capacity as a teacher of midwifery, and he had published several papers on subjects connected with that department of science, which evinced singular powers of observation; these papers were translated into the French, German, Italian, and Danish languages, by learned men on the Continent, which made him known to all the scientific obstetrical practitioners in Europe; accordingly we find that evidence of his peculiar fitness to undertake the duties of the midwifery chair was transmitted from France, Germany, Italy, Denmark, Belgium, Switzerland, and Holland. Amongst the distinguished foreigners who did so were M. Paul Dubois, professor of clinical midwifery in the University of Paris; M. Cuperson, professor of midwifery; Velpeau, Villeneuve, Madame Bouvier, *M.D!* midwife in-chief to the Hospital of Maternity, Paris; M. Colombat de l'Izere, D.M.P., Laureat to the French Institute, and Academy of Science; Cruveilhier, president of the Anatomical Society; and Duparcque, president of the Society of Medicine of Paris; from M. Delmas, of Monpellier; M. Stoltz, of Strasbourg; from Von Siebold, of Gottingen; Saxtorph and Otto, of Copenhagen; from Wilde, of Berlin; Lombard, of Geneva; and from Vrolik, of Amsterdam.

Amongst our own celebrated men who testified as to Dr. Simpson's ability were Drs. Beatty, Collins, Maunshell, Montgomery, Murphy, Power, and Stokes, of Dublin; Drs. Ashwell, Martin, Barry, Carswell, Conquest, D. Davies, Sir James Eyre, Hodgkin, Locock, Lee, and Rigby, of London; the late Dr. Ingleby, of Birmingham; and Dr. W. Carpenter, of Bristol. Whilst the names of the members of our profession in Edinburgh, best known to fame, with the exception of Dr. Thomson, were ranked on the side of Dr. Kennedy.

No canvass for a professorship had for many years occasioned so much excitement, and never, I believe, was one more fairly conducted—*detur digniori* was the motto borne by the candidates and their friends. There were, it is true, certain little great personages of the true manwife-breed, in Edinburgh and elsewhere, perhaps, who on the occasion to which I refer, in conformity with the habits of a numerous body of that class of individuals, acted unworthily, and did their little all to direct the course of events so as to render them subservient to *their* paltry interests. Elaborate notice of the sordid policy of such men is inconsistent with my present position and my immediate design, nor would such an *exposé* as I could make answer any good purpose just now.

> "Disgust conceal'd
> Is oft times proof of wisdom, when the fault
> Is obstinate, and cure beyond our reach."

The petty intrigues for selfish purposes of ignoble-minded men, never yet, I believe (and I trust never will), materially affected the decision of an Edinburgh town council in electing a professor.[3]

On Tuesday, February 6th, 1840, at a full meeting of council, consisting of thirty-three members, the patrons of the midwifery chair, Sir William Forrest, then Lord Provost of the city, proposed Dr. Kennedy, of Dublin, as a fit and proper person to fill the chair; and in an excellent speech did justice to his merits as a most excellent teacher and practitioner. Sir William Forrest's proposal was seconded by Councillor Stoddart, W.S., a gentleman of high intelligence, who also eloquently eulogised the moral and professional worth of the Irish physician. Both Sir William Forrest and Mr. Stoddart spoke most handsomely and eulogistically of Dr. Simpson. Mr. Ramsay, the senior bailie (the magistrate next in rank and authority to the provost in a Scotch burgh), explicitly stating Dr. Simpson's merits, moved that he should be appointed to the vacant professorship. The late Sir William Drysdale, an acute councillor, who had

[1] When Dr. Simpson started as a candidate for the midwifery chair, he was scarcely 28 years of age, and unmarried; the latter want of qualification, however, he obviated with all convenient speed, and before the day appointed for the election he was the husband of an excellent lady, to whom he had been, for a considerable time previously, affianced.

[2] The benefits resulting to medical students, from being members of the Royal Medical Society, are so great and manifold, as to be a cogent inducement, amongst many others, still more potent to make, than to give a preference to Edinburgh, over any other school of medicine, in Europe. I would streauously advise all students, who have it in their power, to become members of the Royal Medical Society, during the first or second year's residence in Edinburgh.

[3] It is certain that Dr. Simpson, as well as Dr. Traill, was elected in opposition to powerful local influence (as I stated before, honestly exercised), contrary to the opinion of O. P. Q., who says that local influence is irresistible. More of that afterwards. In regard to the party that supported Dr. Kennedy, of which I acknowledge myself to have been one, I beg to say a few additional words. Upon an occasion of such importance as the election of a midwifery professor, there are two objects of paramount importance to be taken into consideration—the fitness of the candidate for the chair, and the bearing that the selection made will have on the interests of the public. When the contest took place between Dr. Kennedy and Dr. Simpson, circumstances existed which appeared to us to give the former (strong as were the claims of the latter) a preferable title to the professorship. Let it be borne in mind, that had Dr. Kennedy been elected, neither the Medical School of Edinburgh nor the public would have been deprived of Dr. Simpson's professional services. On the contrary, inestimable as his services have been as a *professor*, they would have been equally so as an *extra-academical lecturer*. Much might be said on this subject, but my present limits forbid it—"I byde my time."

taken a lively interest in the welfare of the city, seconded Bailie Ramsey's motion, and graphically pourtrayed Dr. Simpson's urgent claims to the midwifery chair. After several councillors had delivered their sentiments, uttered in excellent taste, and in a spirit truly praiseworthy, the vote was taken, and, as already mentioned, Dr. Simpson carried the election by *one* vote.[4] I repeat that, from an intimate knowledge of the whole proceedings during the canvass, and from having been an eye-witness of the deportment of the town council on the day of election, I can declare that it was conducted most unexceptionably.

O. P. Q. has spoken most disrespectfully of the published works of the medical professors of the University of Edinburgh. On that subject I shall have something to say before we part; here, it is only incumbent on me to notice the additions which Dr. Simpson has made to medical literature by the publication of his valuable papers.

1. Observations on Diseases of the Placenta (1836).
2. On Spontaneous Amputation of the Limbs of the Fœtus (1836).
3. On Peritonitis in the Fœtus (1838).
4. Enquiry into the Contagious Nature of Epidemic Cholera (1838-9).
5. On Hermaphroditism in the Human Subject and in the Lower Animals (1839).
6. On Malformation of the Fœtus, as produced by Inflammation (1839).
7. On Organic Diseases of the Uterus and Ovary.
8. Remarks on Excision of the Neck of the Womb, and Report of a Case (1841).[5]
9. Antiquarian Researches on Leprosy in Great Britain (1842).
10. Observations on Icthyoses, Intra-uterine (1843).
11. A Series of Papers on a New Principle of Diagnosis and Treatment in reference to Diseases of the Uterus (1843-4).
12. Observations on Turning, and on the Treatment of Cases in which the Child dies from Intra-uterine Disease (1844).
13. On the Alleged Infecundity of Females born co-twins with Males.
14. Memoir on the Sex of the Child, as a Cause of Difficulty in Parturition (1844).
15. Memoir on the Extraction of the Placenta, *before* the Child, in Placenta Prævia (1845).
16. Clinical Lectures on Midwifery, and on the Diseases of Women and Children; by J. Y. Simpson, M.D., F.R.S., &c. &c. Taken in short-hand by Charles D. Arnot, Esq.
17. Graduation Address, delivered by Dr. Simpson on August 1st, 1842.[6]

I call upon O. P. Q. for an expression of opinion as to the merits of Dr. Simpson's "works," the test by which O. P. Q. himself proposed to "judge" the professors of the Edinburgh University. In the mean time, I take the liberty of stating mine, viz., that, as Dr. Christison has done in *his* peculiar department (see his "Treatise on Poisons" and "Commentary on the British Pharmacopœias"), Dr. Simpson has greatly enriched physiology and pathology, especially as pertaining to the obstetric art; and that his writings contain more original information than is to be found in *all* the works on midwifery that have issued from the press in the course of the last fifty years. A bold assertion this! In the spirit inculcated by the courteous and sensible A. W. C., of Grosvenor-square, Manchester, I challenge O. P. Q. to refute it—if he can.

I have now to speak of Dr. Simpson as a teacher. Lecturing "extra-academically," he had, before Dr. Hamilton's death, as already mentioned, acquired a high character. I had the honour of accompanying him, with the learned principal of the university, the Very Reverend Dr. Lee, and the erudite secretary, Sir William Hamilton, to the lecture-room, where he delivered his maiden prelection as a professor. It was, indeed, a splendid performance, and rendered additionally effective by the unpretending manner of the lecturer. From that day Dr. Simpson's reputation as a writer, as a practitioner, and as a teacher, has steadily increased. In the former capacity, he is familiarly known and respected by every scientific physician and surgeon, at home and abroad, in every quarter of the civilised world. As a *practitioner*, he has left all his contemporaries at an immeasurable distance behind, and he has shot far a-head of those who were known as midwifery practitioners long before he was of sufficient age to devote the energies of his powerful mind towards the elucidation of the mysteries of the particular department of science to which he has now, for twelve years, almost exclusively devoted his time and attention. The consequence of which has been, that Dr. Simpson stands proudly pre-eminent as an obstetrical physician; nevertheless, meekness and modesty—

> "O munera nondum
> Intellecta Deûm!"—

remain strikingly characteristic of his whole deportment.

He who gained the high honour of an academical chair in the University of Edinburgh, *solely* by the force of his extraordinary talent, and its peculiar adaptation to the place he fills, was likely to be a most popular and efficient teacher; accordingly we find that, by common consent, he is allowed to be so, not only by his numerous pupils, but by those whose superior knowledge and experience render them still more competent judges.

In speaking of Professor Simpson as one of a body of distinguished men, whose qualifications for the duties of their important offices have been harshly impugned by O. P. Q., I must advert to his recent active exertions in establishing a maternity hospital on a more proper basis than had previously existed in Edinburgh, the want of which was the only defect in the medical school of that city. By a list of the office-bearers, I find that my respected friends, Professors Alison and Christison, Mr. Simpson, the present president of the College of Surgeons, and Dr. John Argyle Robertson, are directors; and that Professor Simpson and Dr. Zeigler (the latter a man of sterling worth and rare professional attainments—with the exception of Dr. Simpson, second I believe to no one in the empire as an obstetrical physician) are ordinary medical attendants. Under the direction and management of such men, the happiest results may be anticipated, and Edinburgh will, I doubt not, ere long, rival other metropolitan cities by her midwifery school, as she has hitherto excelled them in other departments of medical science. As an important step towards an achievement so desirable, Dr. Simpson gave clinical lectures last winter on important cases that occurred in the practice of the charity; it is, I understand, his intention to do so regularly, thus establishing a new and important department of teaching (clinical midwifery) in the Edinburgh medical school—one really of as great utility and necessity as clinical medicine or surgery. It must not be supposed, from what I have said above, that there have not long been opportunities of studying midwifery practically at Edinburgh; besides several maternity establishments, under the management of private teachers of midwifery, a lying-in hospital has existed in the immediate vicinity of the university since the year 1793, under the immediate management of the late professor, Dr. Hamilton, but it was managed on a plan objectionable in one respect—access only being allowed to the pupils of the professor. The *old* lying-in hospital, nevertheless, was a great blessing to hundreds of poor married women annually, and afforded an asylum to many an unfortunate female (who had strayed from the paths of virtue) during hours of bodily pain and mental agony. I would take this opportunity of stating, that the mortality among the patients of the Edinburgh Lying-in Hospital was, comparatively, less than in any similar institution in Europe. From the 21st of June, 1839, to the 15th of October, 1840, two hundred and twelve women were delivered within the hospital, and *all* of them recovered; during the same time, seven hundred and eighteen cases of labour occurred among the out-patients; of these only *one* died, and that in consequence of organic disease of the heart. No lying-in hospital in Europe can, I am certain, show so SMALL a mortality within the same period. In the great Westminster and Dublin Hospitals, from 1 in 80 to 1 in 150 of the women delivered have, for some years past, died during their confinement. Amongst the patients of the Edinburgh hospital, only 1 in 900 died within the period above alluded to—upwards of sixteen months! After what has been said, it will doubtless be granted that Dr. Simpson does honour to the medical faculty of his college. In conclusion, I have only to remark that the shafts of detraction and malevolence, from whatever quarter discharged, or however subtlely poisoned, must fall scatheless at the feet of Dr. James Yarl Simpson, who, as the professor of midwifery, so ably supports the well-earned reputation of the "far-famed" University of Edinburgh as a medical school in the year 1845.

(To be continued.)

[4] The councillors who spoke on the occasion referred to, were Mr. Thomas Johnstone, S.S.C., Dr. Neill, L.L.D., and Convener Clarke, Mr. Alexander Watson, and Mr. Russell, surgeons and fellows of the Royal College—all individuals of high respectability and superior intelligence. The three former spoke in favour of Dr. Kennedy, the two latter supported Dr. Simpson's claims. At the period referred to there were only nine conservatives in the council, five of whom voted for Dr. Kennedy and four for Dr. Simpson; of the other twenty-four *whig* members, thirteen voted for Dr. Simpson, and eleven for his opponent. Thus affording unquestionable proof, that politics had nothing to do with the result, unfortunately a rare occurrence in reference to such an event.

[5] Mention is made of the case referred to in my papers on Uterine and Ovarian Disease, published in Nos. 288 and 292 of the *Medical Times*. The interesting individual who was the subject of the operation resides in the immediate vicinity of my house, in Leith. When the operation was performed, she was sinking under the influence of an exhausting disease (of which incessant loss of blood was an urgent symptom); from the *moment* the diseased portion of the uterus was removed she rallied, became pregnant ten days afterwards! and carried the child until the full time! By a late communication from the north, I learn that she has had *two* children since I left home, three in all since the operation was performed; she enjoys perfect health, and makes a good nurse: thus affording additional proof of the accuracy of my son's remark, made in his report of her first accouchement, that there are few cases on record, in the annals of our profession, which afford more striking proof of the triumph of the healing art over a disease which, from its nature and situation, was considered desperate, and beyond the reach of human aid.

[6] I had the pleasure of hearing that address delivered, which, although (like Dr. Simpson's other productions) characterised by a tone perfectly unassuming, was a most eloquent and impressive oration. The principles and precepts inculcated did honour equally to the head and to the heart of the speaker; and probably produced the effect intended on the unsophisticated minds of the *alumni generosi* who had finished their academical career on the day mentioned above, and were about

> "To stem the world's rude tide."

Dr. Simpson's admirable graduation address, and one delivered by the late Dr. Abercrombie, on his installation as Lord Rector of Marischal College, Aberdeen, contain more sound advice, of a kind conducive to the interests of students emancipated from the restraints of academic life, than is to be found in any modern publication. Dr. Abercrombie's admirable address to the Aberdeen student was afterwards amplified by that indefatigable physician, and published under the title of "Remarks on the Culture and Discipline of the Human Mind" (or an analogous title), in which form it was eagerly read and extensively useful. Dr. Simpson's graduation address was printed and circulated to a limited extent only. I would respectfully suggest to the learned professor that he would do well to imitate the meritorious example of the late Dr. Abercrombie, and give the production of which I speak to the rising medical generation through the medium of his publisher.

Dr. Henry Cooper has been elected physician to the Hull General Infirmary, in the room of Dr. Alderson, resigned.

OBITUARY.—August 29th, aged 60, Hardwick Shute, M.D., Physician to the Lunatic Asylum, Gloucester.

DR. RANKING'S HALF-YEARLY ABSTRACT OF THE MEDICAL SCIENCES.

(To the Editor of the Medical Times.)

SIR,—I am induced to trouble you with the following remarks, in consequence of a somewhat unjust notice of the above work, which has appeared in the *London and Edinburgh Monthly Journal*, of September. I do not write under the impression that a reviewer is to be called in question for any opinion that he may think fit to hazard, but merely to express through your medium, that the editors of the above journal have been guilty of gross misrepresentation (unintentionally, I fully believe) in the statement that I am indebted to them for my abstracts of the foreign journals. He observes, in reference to myself and Mr. Braithwaite, "that the best articles which they give from the foreign journals are coolly taken from us, or others, *second-hand*." Now, Sir, I will not pretend to say what Mr. Braithwaite's habits in this respect may be, but as far as I am personally concerned, I would beg leave to inform the editors of the *Edinburgh Monthly Journal*, that every foreign journal is taken in, and consulted, by myself and my collaborateurs, *first-hand;* and, moreover, that had I been ever so much inclined to have recourse to the pages of the Edinburgh Monthly, in order to save individual labour, the accidental collation of a few of their foreign abstracts with the originals would have assured me, that I had better trust to my own translating, than to the results of the "money and time" which I am accused of purloining. It so happens, that out of near fifty abstracts from foreign journals, which my first volume contains, the great majority were translated by my own pen, and that two only (articles 103 and 104) were borrowed from the *Edinburgh Monthly Journal;* these two were only taken to fill up space, while that portion of my work was going through the press.

I do not, Sir, take notice of this subject, from any fear that the accusation can impair the reputation of the "Half-Yearly Abstract;" the extensive circulation it has already acquired, and the numerous letters of commendation which I have received from strangers in every part of the kingdom, convince me that my endeavours to serve the profession are beyond the range of the artillery of my northern critic.

I am, Sir,
Your obedient Servant,
W. H. RANKING, M.D.

Bury St. Edmunds.

No. 313. SUMMARY. SEPT. 20.

CLINICAL LECTURES ON SURGERY.

BY M. F. LALLEMAND.

Translated for the Medical Times by JOHN WATERS, M.D. M.R.C.S.E., Ancien Elève des Hôpitaux, Membre de la Société des Medecins Etrangers, &c. &c.

CASE.—*Syphilis treated several times without success; Ulcer in the Groin; very complicated Symptoms; Delirium, Paralysis, &c.; Death on the 15th Day; Periostosis; Caries of the Cranium; Meningitis; Encephalitis, &c.*

Evillard, a sailor, twenty-four years of age, of short stature, but very active, suffered from a bubo for twelve months, for which he underwent several methods of antivenereal treatment in the hospitals of Toulon, without being cured. When he came to the Hospital of Saint Eloi, on the 5th of February, 1832, he had in the upper part of the left groin an irregular ulcer about sixty millimetres in every direction, the centre of which was cicatrised in many points; whilst the edges were irregular, red, everted, and fungous, and secreted watery greyish pus. His eyes had a vague and unusual expression; his replies were unconnected; and it appeared to be a great effort of memory for him to state the exact history of his own case. The irregular edges of the wound were pared, and he complained of severe pain during the day. A few days after there was an evident determination of blood to the head, the face assumed a violet colour; delirium came on; and a sensation of fatigue and weakness in the extremities. The patient had no power over the motions of his own limbs, which, when raised, fell from their own gravity: the tongue became red, dry, and rough; the wound in the groin of a bright red, and the secretion from it entirely ceased; the pulse was quick; abdomen very painful, with obstinate constipation; severe pains were felt in the extremities of the right side, and particularly in the shoulder; there also was a red œdematous swelling of the upper eyelid, which extended to the skull. The patient died on the 21st of February, fifteen days after the severe attack.

At the autopsy the following morbid changes were found:—

Cranium.—In the right upper eyelid there was found an abscess which contained pus of a greenish-yellow colour; the surrounding cellular tissue was infiltrated with a similar liquid, which extended as far as the middle of the cheek; the orbital cavity was stripped of its periosteum on the external side, and the corresponding bones were covered with pus, rough, unequal, and more or less deeply ulcerated. On a level with the external third of the fronto-parietal suture, there was a tumour about the size of a small nut, which contained a greenish-yellow, thick pus, in contact with the frontal and parietal bones, from which the pericranium was detached; the surface of these bones was unequal, rough, and covered by pus. On the interior of the cranium, which corresponded with this inflammation of the periosteum, the dura-mater was softened, of a yellowish colour, and separated from the bone by a thin layer of pus, like that which was found outside the cranium; the same discoloration was observed between the two bones, and in the fibro-cartilaginous tissue which fills the suture. The cerebral aspect of the dura-mater was also covered with a purulent matter, similar to that of the external abscess: when the dura-mater was raised, we could see between the arachnoidean layer which covers it and that portion which covers the cerebrum, a very thin layer of a thick purulent fluid, which could be drawn out into long filaments without breaking. Beneath the disorganisation of the dura-mater the cerebrum was found to be softened, and of the same greenish-yellow colour; at the lower part of the posterior lobe of each hemisphere there was an abscess, about the size of a small nut, filled with a yellowish-green matter; above the left ventricle there was a third abscess, twice the size of the preceding one, which was filled with a similar liquid. *Cerebellum healthy.* The dura-mater which covers the anterior fossa of the base of the cranium was soft, of a yellow colour, and separated from the bone by a layer of pus, and it could be detached with the greatest facility. The subjacent frontal bone was ulcerated by pus, and rough on its surface, like that part of the same bone which forms the external side of the orbital vault. The disorganisation of the groin, the tumour of the forehead, and the rough and worm-eaten appearance of the bones of the cranium, declare the action of a venereal virus in this patient. Notwithstanding the many methods of treatment he had undergone, it would appear that the inflammation had extended from the periosteum to the dura-mater, through the sutures; for the fibro-cartilaginous tissue which fills the space between the bones, both on the forehead and on the external side of the orbit, was covered with purulent secretion, and the disorganisation had made greater progress on the external side of the cranium than on the internal; from the dura-mater, the inflammation was easily propagated to the arachnoid and to the cerebrum. From that time the disease assumed an acute progress; nevertheless, complications were added to it, because the constitution was considerably deteriorated, and death quickly closed the scene. When syphilitic symptoms are situated externally, their presence may be suspected by certain distinctive characters which medical men are well acquainted with; but when parts are affected which are beyond our vision, and all the symptoms are owing to a lesion of such an organ as the brain, there is then little to point out the nature of the affection. We can only take into account the antecedent history which the patient gives us, or the concomitant morbid phenomena.

CASE.—*Constitutional Syphilis; Destruction of the Ossa Nasi; Caries of the Os Frontis; Fistulous Opening; Antivenereals—Cure.*

In the month of January, 1844, a carman, twenty-six years of age, of robust constitution, but lymphatic temperament, came to Saint Eloi with the following disorders:—injection and swelling of the face, characteristic deformity of the nose, redness of the skin on the forehead, and at the same time there was a gangrenous ulcer on the os frontis, at the internal angle of the left eye, with a fistulous opening which secreted pus profusely; there was intense ophthalmia on the same side; ulceration and perforation of the palatine arch; pharyngeal redness; tumefaction of the tonsils; hoarseness and an exostosis at the internal side of the left humerus. The patient showed me many particles of bones, which were recognised as belonging to the vomer, the palatine, and ethmoid bones, and which came away from the nose. About two years ago the man contracted chancres and two buboes which were incompletely cured; during the last six months the consecutive symptoms showed themselves, and rapidly assumed the degree of severity which I have just detailed (Venesection of 500 gram., pills of Sedillot, iodide of potassium, sudorifics in large doses). In the beginning of March the patient left the hospital perfectly cured, and only kept the marks of destruction which he bore on his first entry. The diseases of the bones which arise from a venereal taint have a particular stamp, which has been well described by Baron Dupuytren. This consists in the lesions of caries and necrosis. The bone becomes perforated, as if worm-eaten, as we see in caries, but it does not become soft, and will not permit an exploratory stylet to penetrate it; it is always hard and polished, when some small portions come away as in necrosis, just as if they had been separated from the surrounding parts; but the portions thus detached do not appear like those that are separated in ordinary necrosis; for in this latter affection the subjacent parts are covered with healthy granulations, which indicate the natural work of reparation. The bone, thus exposed, becomes eaten and perforated as in caries, with this difference, that it is hard and polished. The disorganisation that is produced by syphilis in the bones cannot then be confounded with caries or necrosis, although there is the greatest analogy between these affections. I have not detailed cases of exostosis, ostitis, periostitis, or of the gummy tumour, &c., because these affections are too well known and of too common occurrence. All medical men know that the pain which characterises these affections is exasperated at night, and particularly towards the morning. As to those affections of the bones of the cranium which extend to the encephalon, they generally begin on the external surface and gradually penetrate to the dura-mater; on some occasions they begin on the inner table of the cranium, and only show themselves externally at some remote period. In these insidious cases, the inflammation may easily extend from the dura-mater to the meninges, and even to the brain, and produce symptoms of encephalitis and meningitis, which do not differ from those of the cases ordinarily met with. We can easily understand, if there does not exist any other indication of syphilis, that it is almost impossible to suspect the primary cause of the inflammation. When the suppuration accumulates between the dura-mater and the inner table of the cranium, it may pass out externally through the perforations which are produced in the bones, and the compression of the brain may be thus diminished, and the coma and paralysis disappear. If these subcutaneous abscesses are opened, the bone is found to be considerably disorganised beneath the cyst, which might induce the belief that it was a case of ordinary caries, but the introduction of a stylet will soon recognise that the rough surface of the cranium is much harder than in caries. This circumstance alone is sufficient to indicate a venereal origin, and warrant the administration of a specific treatment with some hope of success if the arachnoid and the brain be not affected. In whatever manner the affection of the cranium has commenced, it may extend more or less, and more or less affect organs which in time join each other, though coming from different directions. Sometimes, even the vault of the cranium becomes completely diseased without immediately causing death, if the affection is not complicated with a lesion of the dura-mater, and the suppuration flows freely externally by the fistulous openings. I have a specimen in my museum where the cranial vault is entirely perforated like a large skimmer. The subject to whom it belonged had for many years numerous fistulous openings, the true cause of which could not be ascertained. However, generally speaking, the history, and the alterations of the bones, will not allow us to entertain a doubt as to the syphilitic origin of these numerous fistulous openings. This man died from encephalitis, and death was only caused by the brain itself becoming diseased. This case proves to what an extent the disease may arrive on the exterior of the cranium without immediately affecting the powers of life. Perhaps, even in this patient, the disease might have been arrested in the beginning if the true cause could be ascertained.

CASE.—*Syphilitic Tumour on the Lip; Antiphlogistics; Antivenereals; Cure.*

Joseph Ropetti, a Swiss tumbler, of vigorous constitution, and born of healthy parents, came to the Hospital of St. Eloi on the 2nd of February, 1827. The edge of the lower lip of the patient was affected by an indolent tumour, of about the size of a large pea, hard, very hot, and of a red coppery colour, and covered at its summit with a blackish crust. The lymphatic ganglia of his neck were engorged, and of about the size of a small nut. This tumour was produced by the re-union of two small pimples, which came on two months before; they gradually drew nearer, became united and covered with a crust, which he removed on several occasions, but which was again reproduced and had increased in extent. Mercurial ointment and sudorifics were prescribed for the patient, at Nismes, although he asserted he had never had a venereal affection, and that he had never felt any of the symptoms that characterise it. By these measures, and the application of poultices to the neck, the glands of this region became much smaller, but the tumour did not change its aspect.

Antiphlogistics (bleeding, leeches, baths, and poultices) were tried in the hope of removing the inflammatory progress in the tumour, and thus effecting its resolution. Almost immediately a remarkable change took place, the tumour became sunk and diminished in size; but from the 26th of February, it remained in a stationary condition. Shortly afterwards it increased rapidly, and it was then that Ropetti was put under an antivenereal course, although he still persisted in denying the possibility of a syphilitic infection. At the end of fifteen days the tumour assumed a bright vermillion colour, it diminished each day, and in about two months it had completely disappeared.

This affection was constitutional, and offered very different characters from the cases we have observed where the infection was applied in a direct manner to these parts, as the result of impure kisses (see cases 7, 8, and 9). There existed, moreover, an inflammatory state in the tumour, which required the use of antiphlogistics.

CASE 27.—*Venereal Ulceration of a Cancerous Aspect affecting the Upper Lip; Antiphlogistic and Antivenereal Treatment; Cure.*

Mailhouta, a Marseilles sailor, fifty-two years of age, contracted about the age of eighteen a blenorrhagia, for which he was treated at the hospital, at Marseilles, during four months, by sudorific infusions and mercurial pills; the affection left him, and restored to health and vigour, he continued his maritime pursuits until eight years afterwards, when there came on a general eruption of red and flattish pimples, which was considered to be "itch," was treated accordingly, and disappeared in eight days. Four years afterwards he suffered from an inflammatory sore-throat, which was quickly removed by resolvent gargles. Immediately afterwards a small ulcer, surrounded by a reddish circle, formed at the anterior part of the right upper lip. This was considered to be of a scorbutic nature, and tobacco was applied to it; the ulceration nevertheless remained stationary for three months, it then made considerable progress, and in a short time affected the whole of the upper lip. In September, 1819, the patient came to the hospital, at Marseilles, where they considered the affection to be of a cancerous nature, and plasters were applied, with the properties and composition of which he was perfectly unacquainted. Without consulting any one, he himself frequently touched the ulcer with the sulphate of copper, in the hope of destroying the virus, and of accelerating his recovery. Finding no improvement, he came to Montpellier, and entered the Hospital of St. Eloi, in the month of April, 1820.

The upper lip was ulcerated in its whole extent, from its attachment even to the edge, and from one commissura to the other, and in the centre there was a considerable loss of the substance of the lip; the ulcerated surface was covered with small and irregular granulations, which were streaked with a yellowish colouring matter, and on ther points with a blackish matter; the edges oere thick and everted, painful and hot, affected with lancinating pains, and presenting all the appearances of cancer. However, from the history with which the patient furnished me, I was induced to attribute the alteration to syphilitic virus, and I prescribed the mixture of Van-Swieten. Some time afterwards, perceiving no change to be effected by this treatment, I had recourse simultaneously to antiphlogistics (bleeding, leeches, baths, and emollient poultices); the edges of the ulcer became depressed and drew nearer, and from that time cicatrisation went on rapidly, and was complete in the month of June; the antivenereal treatment was continued up to that period, when the patient left the hospital. On arriving at Majorca, in the month of September, he perceived that there formed about the edge of the right upper lip a small white pimple, which was very painful, and soon ulcerated; consequently, Mailhouta came back to the hospital, at Montpellier, in the month of October in the same year. The ulceration had extended over all the upper lip, but it had not the same appearance as formerly; it was of a greyish colour on its surface, and was superficial; the edges were not hard or everted. The mixture of Van-Swieten was again given to him, and emollient poultices were applied to the ulceration. About the end of December, the cicatrix having been for some time perfect, the patient once more left the hospital cured.

This affection was evidently of a syphilitic nature. However, from the stimulating topical applications that had been used in the commencement, the ulcer had assumed a cancerous nature. It is not uncommon when venereal ulcers are exasperated, for them to degenerate into true cancers. In the cure of this patient it was necessary to combine the most efficacious means to overcome these two diseases; the specifics that were used destroyed the venereal virus, which was the primary cause of the ulceration; the antiphlogistics served to recal the degenerated tissues to a more natural condition. The first antivenereal treatment being incomplete, the affection of the lip again appeared, but only with the characters of a constitutional syphilis, and disappeared finally by the employment of antivenereal remedies.

In the preceding case the symptoms of disorganisation had not so far advanced, and recovery might have been more rapid; but in this case time and perseverance were required, and the combined influence of two methods of treatment, to arrive at that result. Generally speaking, ulcerations on the lips are primary, that is to say, they are produced by a direct infection; however, consecutive ulceration sometimes occur on those parts as well as elsewhere, when they are frequently irritated, but they present very different characters, as we may see by comparing the cases of primary infection of the lips with those which we have just reported.

CASE.—*Degeneration of the Tongue of a Cancerous Appearance; many and ineffectual Modes of Treatment; Antivenereals; Cure.*

A distinguished practitioner, living at Lyons, showed me some years ago, a lady who was cured by antivenereals of an affection of the tongue, which was of a cancerous appearance, and which occupied almost the whole extent of that organ. The extent of the disease and the severity of the disorder prevented him from having recourse to an operation. Despairing of success, an antivenereal treatment was administrated from some vague suspicion of a syphilitic taint which was supposed to have been communicated by her husband. Gradually the motions of the tongue were restored, the induration disappeared, and the organ assumed its normal size. Analogous cases are not uncommon: I have related this one in preference to others, in consequence of the extreme severity of the disease. Sometimes ulcerations arise round the tongue, which are owing to carious teeth; and the irritation being kept up by the almost constant friction, cancer may affect the organ. But when these teeth have been extracted, the ulceration soon changes its appearance, and cicatrisation rapidly commences.

There are other kinds of ulcerations which occur round the tongue without any apparent cause, or which still continue after the teeth have been extracted, although they were considered to be the only cause of these alterations. In all of these cases we must not be in a hurry to have recourse to an operation, or to neglect the patients. When we attentively inquire into their antecedent history, we shall be sure to find sufficient proof of the existence of a venereal cause; we must then adhere to this belief, and prescribe an antivenereal treatment, which is the only hope of success. If the diagnosis be correct, the cancerous character of the affection will disappear, under the influence of the specifics for syphilis, without leaving either induration of the tissues, or an impediment to its proper function.

In less severe cases, these ulcerations of the tongue are frequently accompanied with white spots of a metallic appearance; the mucous membrane looks as if it had undergone a true transformation in these parts; it is covered with a whitish pellicle. Strict attention to diet will generally cause the disappearance of this affection, but it frequently comes on again. They have some resemblance to the aphthous ulcerations, which we sometimes see in the mouths of smokers. Again, the tongue is often furrowed in every direction, and particularly in a longitudinal one; frequently intense pain is felt at the same time. As a general rule, we should attribute these lesions to a syphilitic cause, if the existing one be not easily discoverable.

CASE.—*Syphilitic Phthisis Laryngea complicated with Ascites; Antivenereals; Cure.*

M. C——, a banker's clerk, aged 49, of a lymphatico-sanguineous temperament, and much addicted to sexual intercourse, experienced, when 26 years of age, a complete loss of the voice without any pain; this state lasted two years, and was treated by emollient drinks; he had, moreover several attacks of rheumatism. In the month of January, 1824, he experienced every afternoon, about three o'clock, a slight rigor, which was followed by considerable heat. This indisposition seldom prevented him from following his usual occupations. He then felt heat in the windpipe, and deglutition was sometimes very painful. Dr. Dunal prescribed emollient drinks. About this time the left upper extremity was attacked by rheumatism, accompanied by pain and slight swelling. In the month of April a severe paroxysm of fever came on; the pain in the arm was very severe, and the patient was obliged to leave his office; the lower extremities were frequently swollen and œdematous, particularly towards the evening; respiration was stertorous; the urine thick, and of a deep red colour. Ascites then came on; hydrops pericardii, and an effusion into the pleura had previously existed. Being put under the influence of diuretics and antiphlogistics, the ascites and rheumatic pain disappeared, but the slow fever persisted for some time, and the pain in the windpipe gradually increased. It was at this time that I was consulted. The chest appeared to be healthy; however, the persistence of fever and the severity of the laryngeal pain announced the work of inflammation in the larynx (leeches to the neck, two large issues on the lateral parts of the larynx); slight relief. Shortly afterwards, a return of all the symptoms (venesection, mustard pediluvia, six issues to the larynx in the space of six months); momentary relief. One day, on examining the issues, I perceived a slight exostosis on one of the clavicles. I strictly interrogated him as to whether he had ever had syphilis; he acknowledged he had contracted two blenorrhagias, one twelve, the other four years before. From these facts, a mercurial treatment was administered (pills of Sedillot, one night and morning). At the end of five or six days, the irritation of the larynx having increased, the employment of the mercury was suspended. The disorder grew worse; the patient breathed with greater difficulty, and he could not swallow fluids. Plinck's gummy preparation of mercury was ordered, care being taken to diminish the dose as the state of the patient required. At the end of a month all the alarming symptoms disappeared, and in three months the patient was restored to perfect health. From that time the state of his health improved, and during twenty years afterwards he had no relapse; his voice, however, never became strong, and a lengthened conversation produced fatigue. The cicatrices in the larynx were probably the cause why the tone of the voice was not restored.

PROGRESS OF FRENCH SCIENCE.

(FROM OUR OWN CORRESPONDENT.)

Paris, September 5, 1845.

Academy of Sciences.—Meeting of September the 8th, 1845. M. Elie de Beaumont in the Chair.

Structural Anatomy—Dr. Bourgery on the Nerves of the Serous Membranes.—The serous structures of the human body have hitherto been deemed deficient in nerves. Dr. Bourgery not only states he has discovered their existence, but asserts they are to be found in greater abundance in the serous than in any other textures. The nerves of serous membranes vary in diameter, 0·0001 of a millimetre, and 0·00002 of a millimetre (*i. e.* 1-30th and 1-150th of a line), intercepting in their progress small polyedric spaces not exceeding in size 1-5th of a millimetre (0·0002 of a millimetre), and being sheathed in their course by an elastic fibrous integument.

Their origin varies according to the region upon which the membrane they belong to spreads, the cerebro-spinal system furnishing the nerves of the serous coats of the muscular parietes of the trunk, the extra-visceral plexus being the source of the nerves distributed to the serous investments of the rachidian surfaces; and the common intermediate space, *i. e.*, the diaphragmatic and mediastinal regions, the circumference of the pelvis, &c., deriving their nerves from both sources.

The nerves terminate indifferently in muscular and serous tissues—an anatomical fact which clearly shows that the same nerve is composed of rami, destined to fill ultimately different functions. The termination of the nerves is occasionally in the shape of penicillated fasciculi; and of isolated fibres, both orders of terminal divisions promiscuously mingling with each other.

In the peritonæum, the nerves are distributed in the following manner:—the anterior wall of the membrane receives them from the muscular divisions of the six last intercostal branches, and the two first lumbar; and also from a double plexus—one arising from the solar ganglion, descending along the umbilical vein; the other ascending from the pelvic ganglions on the passage of the urachus and umbilical arteries. The posterior portion of the peritonæum, receives numberless nerves from the ganglions situated in the vault of the diaphragm, and the lumbo-iliac region; the splanchnic peritoneal nerves are here inextricably mingled with rami emanating from the spinal system; the peripheric anastomosis of the cerebro-spinal and ganglionic systems being nowhere better demonstrated. These nerves are distinctly seen with the microscope, or a strong magnifying glass (from 3 to 10 diameters), or preparations which have been allowed to macerate in acidulated water (1-110 to 1-200 of azotic acid).

Fossil Remains of a "Quadrumane" found in Essex.—Professor R. Owen, F.R.S., corresponding member of the Institute, present at the meeting, stated in a written communication, that on August 12th, 1845, a small series of fossil mammalian remains was brought to him by their collector, Mr. Ball; amongst these remains was a portion of jaw, with a molar tooth, supposed by Mr. B. to be human. This fossil presented all the characters due to change of texture, colour, and adhesiveness of the tongue of the other fossils of the extinct mammalia. It was found at the village of Gray's Rhurrock, county of Essex, and was taken out of the sandy bed at a depth of fifteen feet below the present surface; a comparison of the molar tooth in question, with the specimens in the Hunterian collection in London, determined it to belong to the quadrumanous order, and the genus "Macacus;" a conclusion confirmed by further comparison with the collection of Osteologic specimens of the "Muséum d'Anatomie Comparée."

The present interesting discovery, coupled with the fact that at the present day a species of Macacus still lives and propagates on the rock of Gibraltar, and another species is indigenous in Japan, whilst numerous genera of quadrumana flourish in Southern Asia, affords additional weight to Professor Owen's opinion, that Europe, Asia, and Africa, ought to be regarded, in relation to the geographical distribution of mammalia, as *one* great natural province; and further, that the genus macaque, like the genus elephas, rhinoceros, hippopotamus, and hyæna, formerly and prior to the insular separation of Great Britain from Europe, had a much wider distribution over the Europæo-Asiatic continent than at the present day.

Keratoplastic Operations.—Transparency of the Engrafted Cornea. By Dr. Feldmann. The transplantation of the cornea from one animal to another is an operation generally unsuccessful, inasmuch as the engrafted cornea soon loses its transparency; in order to prevent this circumstance, which takes away the entire benefit of the operation, Dr. Feldmann recommends the cauterisation, with the solid nitrate of silver, of all vascular formations on the engrafted membrane.

Carious Teeth.—Dr. Schlund, in cases of diseased teeth, proposes the resection of the decayed portion, and presents an instrument he has invented for the operation.

Mechanism of Fractures—Chassaignac on the Solidity of Bones, and their Mode of Resistance to External Injury.—Dr. Chassaignac divides fractures into four classes, according to their mode of production:—1. Fractures by elongation of the fibres of the bone—*i. e.*, those of the patella, olecration, &c. 2. Fractures by incurvation. 3. Fractures in which the bone is crushed. 4. Fractures by exaggerated torsion of the bone. These modes of action of the fracturing causes, sometimes exist singly in producing fracture, and occasionally are combined with each other. The author further remarks upon the prismatic shape of the long bones, and upon the mode of resistance of triangular prisms to external violence. Interesting experiments are brought forward to show, for instance, that the tibia will carry a much heavier weight, if that weight bears upon the crest of the bone, than if it rests upon one of the faces, thus illustrating the known law of solidity of prismatic bodies, and also the remarkable disposition of the bones in the human body; in consequence of which they are better fortified against external violence, in those precise parts where they are most exposed to encounter it. Dr. C. concludes by stating that the bones attain their maximum of solidity from the twenty-fifth to the forty fifth year of life, from which period they gradually and progressively lose their power of resistance, from the action of three causes: 1st, the interstitial absorption of bony matter; 2nd, the relative predominance of the phosphate of lime; and, 3rd, the absorption in advanced years of this latter deposit,—a cause which Dr. C. is the first in mentioning.

The Meteor at Monville.—Professor Bouillet had been called upon by various insurance companies to state his opinion as the *nature* of the late disastrous phenomenon observed at Monville in Normandy, inasmuch as they will be liable to heavy reimbursements in case the accident is found to have resulted from the action of lightning, whereas they cannot be under any responsibility if the fatal events have been the result of the wind; in one word, is the meteor to be regarded in the light of a *storm* or in that of a *hurricane*? The professor, in an elaborate report on the subject, states as his opinion, that the destruction was due, in the greatest measure by far, to the action of the wind, but slight evidence existing of the action of lightning. The reporter argues, that the electric condition of the spikes and bars of the fated factories can have no weight in deciding the question, as it is more than probable that the spikes of all engines working for a certain length of time in given positions must acquire magnetic properties without the intervention of any visible discharge of electricity.

Academy of Medicine; Meeting of Sept. 9th, 1845. Dr. Roche, vice-president, in the chair.

Pulmonary Emphysema. By Dr. Piedagnal.—Dr. Piedagnal read a paper on emphysema of the lungs, in which he attempted to establish that death generally results from the penetration of the extravasated air into the vascular system. In support of this opinion, he brought forward several cases where emphysema existed, generally complicated with other diseases, and in all of which bubbles of air were detected in the arterial system of the brain. In conclusion, the author pointed out the great importance of this fact in relation to forensic medicine, and endeavoured to prove that many cases of sudden death during apparent health, and when no lesion has been detected on examination of the body, may be referred to this cause. He stated, moreover, that emphysema and sudden death after parturition were often to be attributed to violent efforts during labour, in consequence of which, rupture of the air cells taking place, a certain amount of air was introduced into the vascular system.

Several gentlemen were afterwards called upon to make promised communications; none being present, the meeting terminated at a quarter to four.

Surgical Society; Meeting of August 27th. M. Monod in the chair.

Abnormal Anus—Pathological Anatomy.—Dr. Malgaigne does not believe, with Scarpa, the infundibulum of the abnormal anus to be formed by the remains of the hermial sac. He relates the following case: A man, ætat. 49, bore, for the space of twenty-four years, an irreducible crural hernia: strangulation and gangrene set in, in May, 1844, and on the 10th of June following, the slough having separated, an abnormal anus formed, through which fæcal matter escaped, the greater part of the fæces, however, following their natural course. The patient entered the hospital of Saint Souis in March, 1845, when tents were introduced during two months, when diarrhœa, erysipelas, and crural phlebitis occurring on both sides, carried him off on the 16th of August, 1845. The anatomical preparation showed the abnormal anus, situated in the left groin, with its upper lip closely attached to the Fallopian ligament. The infundibulum leading into the gut was extremely short in its superior portion, but was much longer in its other regions. A catheter was introduced with great ease into the intestine below the opening, but it was very difficult to pass it into the gut above the artificial anus. A portion only of the diameter of the intestine was destroyed, and all round the ring the gut had formed intimate adhesions with the peritoneum of the abdominal wall. What M. Malgaigne chiefly insists upon is, that no trace of the hernial sac can be detected, and that the parietes of the infundibulum are lined and formed by the intestine itself. A double spur exists in the intestinal cavity, the superior one being the longest, and the mesentery formed *no cord* as is usual in analogous cases.

Polypus of the Rectum.—Removed by Torsion.—Dr. Maisonneuve presented a polypus extracted from the rectum of a man, aged fifty, and situated two inches above the anus. Painful stools, tenesmus, and bloody dejections were the accompanying symptoms. Not choosing to divide simply the pedicle of the tumour, a line and a half in diameter, an operation which might have occasioned hemorrhage, or to tie the polypus, ligature being sometimes followed by unpleasant consequences, Dr. M. fixed the pedicle with a forceps, whilst he twisted off the tumour with another forceps, a plan suggested to him by M. Récamier, and which is analogous to the method first adopted in the torsion of arteries.

Extraction of a Fragment of Glass from the Eyeball. By M. Lenoir.—A joiner, working at a glass window, was struck by a fragment of glass in the right eye, and called Dr. Lenoir to examine the organ. The cornea was divided at its inner third by a vertical wound, encroaching, above and below, upon the sclerotica; from the superior angle of this division protruded a small portion of the iris and of the ciliary ligament; further on, touching the upper lid, the surgeon felt distinctly a solid body entangled in the eyeball. The foreign body proved to be a fragment of glass of a triangular shape; the basis of the triangle being more than half an inch in length, and each of the sides more than an inch. It was extracted with a dissecting forceps, and the patient is doing well.

Dental Surgery.—M. Monod relates a case in which pressure of the wisdom tooth or the root of the second molar occasioned much inconvenience and suffering. A gentleman became deaf in both ears without any evident cause, at the same time he complained of severe rheumatic pains in both rami of the maxilla. No tooth was decayed, but the localisation of the pain in the vicinity of the second molar induced M. Monod to remove it.

After the operation the symptoms immediately disappeared. On examination of the fangs of the extracted tooth, they were found to be worn and dovetailed by the pressure of the wisdom tooth.

A man, aged 60, whose teeth had all fallen away, presented, near the angle of the maxilla, a fistulous opening, kept open by the presence of necrosis. On examination of the mouth, a tumefaction was noticed in an alveola: the part was carefully probed, a tooth was discovered and extracted, and the fistula closed; it was the wisdom tooth.—M. Guersant: A girl, ætat. 16, was brought to M. Guersant, with a fistulous opening in the anterior region of the neck, the consequence of an abscess. On examining the teeth, he found that one of the inferior canine teeth was discoloured, and that he could introduce a probe between the tooth and the alveola: the tooth was removed and the fistula cured without delay.—M. Chassaignac remarked that in preparing the lymphatics of the head and neck in young subjects, he had often met with an anatomical change of structure, of some interest to the present debate. The tooth examined in the alveola presents no alteration; but the maxilla being completely denuded, is found perforated with several small holes in the neighbourhood of the root of the tooth. If this diseased lamina of bone be removed, the fang of the tooth is generally found diseased and surrounded with pus. This intra-alveolar caries must often escape observation during life, and is, doubtless, in many instances the cause of the enlargement of the maxillary glands, and of certain purulent collections of the same region.

HOSPITAL LA PITIE.—PROFESSOR PIORRY.

Whining murmur of the Heart.—A young woman, convalescent from an attack of partial peritonitis, was auscultated with a view of ascertaining if she presented the stethoscopic signs of chlorosis. A distinct *whining* murmur was heard, corresponding with the first sound, and louder at the apex than at the base of the heart. The pulse remained regular, and no disorder could be detected in the mechanism of the circulation. No fluid was effused in the pericardium, and the lungs were healthy. Professor Piorry attributed the abnormal sound observed, to the percussion of the apex of the heart against the stomach in a state of distension from air and liquids; a supposition confirmed by the fact of the *whining sound* disappearing suddenly on the ingestion of a glass of water. The patient, suffering from no symptoms of any importance, was discharged.

LA CHARITE.—M. RAYER.

The following interesting case has been observed in Dr. Rayer's wards by M. Clerault, D.M.P.:—A lad, ætat. 17, entered the hospital with the premonitory symptoms of variola, on May 30th, 1845: he had never been vaccinated. The vaccination was performed on the 2nd of June, and on the 11th the eruption of small-pox appeared, nine days after vaccination, and twenty-eight since the first prodromic manifestations. The vaccine pustules presented the following modifications, due, no doubt, to the co-existence of variola:—1. Great slowness in their progress; 2. No vaccine tumour or subcutaneous induration. The inflammatory areola was very much circumscribed. The variolous affection seemed to have been modified by the inoculation: 1. With regard to the sudden change which took place after vaccination, violent prodromic symptoms being succeeded, after twenty-eight days, by a mild and discreet variola; 2. By the absence of any secondary fever.

BEAUJON.—DR. ROBERT.

Fracture of the Clavicle.—In a case, at present under treatment, in which the internal fragment of the bone protrudes considerably, Dr. Robert has maintained the fracture by the application of two splints, one *behind*, the other *in front of* the clavicle, supported by the spica bandage of the shoulder. We conceive this mode of dressing the fracture can apply to a very small number of persons: in the present instance, the supra-clavicular space is sunk deep behind the bone, so that the posterior splint really bears upon it. The axillary cushion is not used, nor is the arm supported in a sling.

DAN. M'CARTHY, D.M.P.
President of the Parisian Medical Society, late Interne of the Hospitals of Paris.

PROGRESS OF GERMAN MEDICAL SCIENCE.

By SIGISMUND SUTRO, M.D.

Displacement of the Heart in consequence of a Pulmonary Disease.—An officer, ætat. 39, previously healthy, was affected in the summer of 1835, by a nervous fever, with gastric disturbance, which continued for a long time, and caused a dread of consumption during his long convalescence. During his confinement, which lasted about five months, the patient had always lain on the right side, which proved the right lung to be chiefly affected. When at last he began to walk about in the commencement of 1836, he complained of difficult respiration and palpitation of the heart, more perceptible in the right than the left side of the chest. These symptoms were joined in the spring of 1838, by occasional vertigo and hæmoptysis, which returned every year in an increased degree. During the intermissions the patient was pretty well, and when he observed a strict diet could follow his avocations, and even undertake small journeys. In the autumn of 1844, on the 21st of October, he was again affected without any precursory symptoms, with a very violent hæmoptysis, so that he lost two quarts of blood in seventy-two hours. The hemorrhage was stopped by the use of infusion of digitalis and afterwards the diacetate of lead with opium, and the application of ice over the chest. After this effusion the patient was extremely exhausted and unusually dejected. He predicted his immediate dissolution. The previous morbid symptoms increased visibly in intensity. The violent palpitation, particularly perceptible on the right side of the chest, became transformed into a constant humming. The pulse was exceedingly accelerated, soft, and tremulous; respiration much obstructed and only possible by bending the body forward; sleeplessness and daily decrease of strength, till death ensued on the 11th of November. The autopsy (confined to the examination of the chest) showed the body unusually emaciated; thorax exceedingly flat; the left lung firmly adherent in almost its entire extent to the pleura and ribs; its substance full of soft tubercles. The right lung, which also presented tubercular matter, had the appearance of a narrow slice of liver, and extended along the ribs, to which it was firmly adherent. The heart lying under the sternum, but mostly in the right cavity of the chest, was enlarged, particularly in its right ventricle, which was filled with coagulated blood. Its texture loose; no change in the valves; a large polypus in the left ventricle probably formed during the last agonies.—*Dr. Loewenhardt, of Prenzlau, in Casper's Wochenschr.*

Notices from Practice—Antagonism between the Salivary Glands of the Mouth and Liver.—The author observed in six cases occurring in men from twenty-two to fifty-four years of age, a constant suspension of secretion of the saliva during morbid increase of the hepatic functions. Grief and depressing mental influences were invariably accompanied by dryness of the mouth, which stood in proportion to the intensity and duration of the mental depression, and the author saw the tongue and fauces so dry on some occasions, that the finger could not discover a trace of moisture (thus, not only the salivary but the mucous glands of the mouth and tonsils must also be affected). No thirst accompanied this dryness of the mouth.

Sympathy between the Cutis and Uterine Mucous Membrane.—In apparently healthy women, who had previously borne children, the author frequently observed in the two last days of the period of gestation an ecthymatous pustular or furuncular eruption, appearing at the upper part of the thigh, or on the labia pudendi. These pustules were from one to ten in number.

Does the Green Colour of the Stools caused by Calomel proceed from Bile or not?—The chemical analysis of the stools caused by calomel, by Simon, proves that their green colour is caused by a considerable quantity of bile. Practitioners may easily decide this question; for if the green colour does *not* proceed from bile, it must be found in the stools, whether calomel be given for a short or long period; and, if it be produced by bile, it must cease to show itself as soon as the bile is evacuated; and this must particularly take place in acute diseases (as the author witnessed in one case), where the small quantity of food taken can only furnish a slow and inconsiderable supply of bile.—*Dr. Schweich in Oesterlin's Jahrbuchen.*

A few Remarks on the Anatomical and Physiological Differences between the Infantine and Adult Organism.—The physiological peculiarity in the organism of children, so materially connected with pathological processes, is by no means sufficiently explored. Comparative measuring of the capillary vessels of children and adults (in the lungs, liver, kidneys, intestinal canal, skin, &c.) shows positively that the diameter (in the former) exceeds not only relatively but absolutely that of the same organs in the latter. In the same proportion the capillary meshes in children are relatively and absolutely larger than they are in adults. The follicular apparatus of the infantine intestinal mucous membrane also exceeds that of adults in size, a proportion which probably exists in the other mucous membranes and the external skin. A more rapid and abundant secretion is of course favoured by this peculiarity, necessary for the active process of nutrition in a healthy state, and causing in acute diseases rapid effusions and abundant discharges. This accounts for the tendency to inflammation in children, and the circumstance that irritation can easily produce disease and death in them before real structural change has taken place. Thus, we frequently find, for instance, profuse secretions, in children, from the respiratory and alimentary mucous membrane without being able to discover any change of the tissues, such as is generally produced by inflammation.—*Dr. Bergin Journal fur Kinderkrankheiten.*

On the Pneumonia of Children.—In adults, pneumonia generally affects the right side, and seldom both; in children the contrary takes place. The violent inflammatory fever is also absent in the latter, but the prominent symptoms are, diminished oxygenation of the blood, depressed state of the cerebral functions, and suffocation. Children in pneumonia are often affected with great somnolence; pale bluish complexion, cold, and blue ædematous extremities. The mouth is frequently filled with frothy saliva, respiration accelerated, irregular, with distension of the nostrils, and violent action of the diaphragm. Cough is generally present, particularly if bronchitis has preceded the pneumonic affection, but may be entirely absent, or at least inconsiderable. *Ronchus crepitans* is not of the pretended importance in children, for the author observed it momentarily produced in perfectly healthy children by the first deep inspiration, after several superficial ones. Percussion does not furnish more certain results than auscultation, for the inflammation must be spread to some considerable extent before a safe inference can be obtained by percussion, and then there is small prospect of a favourable result. Bronchial respiration is more important, but difficult to distinguish. As regards percussion the same may be said, for a safe result can only be obtained if the inflammation be spread to some extent. On account of the lobular nature of pneumonia in children, abscesses are frequently formed, and sometimes to such an extent, that the whole tissue of the lungs is interwoven with suppurating cavities. If the abscesses are superficial, pleurisy ensues; in one case, perforation of the lungs was produced with discharge of air and pus into the cavity of the pleura.—*Dr. Berg, ibidem.*

On the Enteritis of Children.—Acute inflammation of the intestinal mucous membrane, if not very extensive, generally appears in children with the symptoms of cholera—viz., severe vomiting and watery whitish-yellow or light-green stools, often mixed with white flakes or bloody mucus; violent thirst; coldness of the extremities, small, quick pulse; general collapse; restlessness or coma. After twelve hours the influence on the general health of the child becomes distinctly perceptible. It is difficult or impossible to determine which part of the intestinal canal is affected. It seems, however, that the symptoms are more violent in inflammation of the small intestines, and subsequent exudation, or softening of the mucous membrane. Two species of inflammation are often distinctly determined by the post-mortem examination, the one having its seat in the villi, the other in the follicles. In the

former the epithelium can be easily separated from the villi, the subjacent layer being considerably softened, whilst the inflammation of the follicles causes increased secretion, in consequence of which the follicles burst. The author found Böhm's assertion confirmed, that large pieces of ephithelium are found in the cholera-excretions, shaped like the finger of a glove, but he does not believe them to be the covers of the villi, but rather the epithelium of the follicles of the large intestines. In chronic enteritis (a common cause of atrophy), anatomical investigation shows the deposit of a black pigment in the villi, the follicular apparatus of Peyer's glands, and round the follicles of the large intestines. The whole intestinal walls often appear, in consequence, as grey as slate, whilst the follicles appear ulcerated under the microscope. The author thinks he has ascertained (by injecting the vessels of diseased intestines) that this pigment is caused by obstruction and decomposition of the blood.—*Idem, ibidem.*

On a more correct Examination of the Middle Ear, and the cure of Catarrh of the Eustachian Tube.—A view has recently existed that compressed air penetrates into the Eustachian tube during the examination of the middle ear, by means of the catheter and douche, and produces a humming noise if mucous be present, whilst in the absence of this obstruction; the tympanum gives an audible sound by the air striking it. The author contradicts this opinion entirely. The penetration of the compressed air from the douche-apparatus (through the catheter) into the middle ear, only takes place if the tympanum be perforated; but otherwise it is impossible. For as the middle ear is closed at the tympanic cavity by the tympanum, the air contained in it cannot escape before the penetrating stream of air, but is only compressed in a slight degree; neither the patient nor the tympanum could endure the considerable pressure, which is necessary in a normal state for the compression of the air contained in the middle ear, in order that the new stream of air may traverse the Eustachian tube. If we further consider that the air remaining in the middle ear before examination becomes warmed by the surrounding tissues to 30° R., and expanded, offering some little resistance, it is evident that the compressed air introduced through the catheter, only moves towards the palatal opening of the Eustachian tube, before it escapes into the fauces. If this can be maintained of a perfectly permeable tube, it is still more the case in a tube obstructed by tough mucus. If the stream of air introduced by the catheter does not arrive at the tube, a humming noise cannot certainly be perceived in the tube; nor can the tympanum be projected by the penetrating air, if the tube be permeable. On the other hand a mucous obstruction of the tube may be present without any mucous rattling, and whilst the tympanum is perfectly inflated. In consequence of the above diagnostic uncertainty, the author does not employ the air-douche for the examination of the middle ear, but introduces a gut-string (generally an E-string) into the tube through the catheter, after he has previously softened one end in his mouth. This method of exploration possesses the advantage (besides the stimulation of the tube) of freeing the passage from mucus by its introduction, and soon causes an improvement in deafness from mucous accumulation. If the string when withdrawn be not covered with mucus, nor the introduction accompanied with relief, nervous affection of the ear is to be assumed. Thus the usual remedies intended to remove the inflammatory affections, mucosities, and obstructions of the Eustachian tube (as introduction of vapours, water, and compressed air) by no means answer the purpose, inasmuch as they do not reach their place of destination, unless the affection of the tube be complicated with a perforation of the tympanum. The ethereal vapours employed in nervous deafness and narcotic infusions do not reach the destined space. The author asks, then, how so many cures have been effected notwithstanding the erroneous path followed in the treatment? He refers, in answer, to an observation of *Lentin's*, who cured a deafness caused by mucous in the Eustachian tube, by frequently rubbing the palatal orifice of the Eustachian tube with a piece of sponge fixed to a little staff. This cure can only have been effected by the influence of the air on the palatal opening of the tube, whilst the friction probably caused a more active circulation in the tube itself, and thus the tough mucus may have become more fluid and fit for discharge into the fauces. The cure of nervous deafness by means of ethereal and narcotic vapours may have been produced by sympathetic influence, between the nervous branches of the trigeminus in the fauces and the portio-mollis. The author admits, however, that the introduction of a string into the tube for the purpose of removing mucus is a painful harsh means, but he knows of no other remedy by which the purpose can be attained so soon.—*Dr. Lode in Hufeland's Journal.*

On the Analysis of Beer.—The means used by the authorities to discover the genuine composition of beer have been different. Formerly it was thought sufficient to examine the physical qualities of the beer, as smell, taste, colour, purity, and specific gravity. The taste does not give a certain knowledge of its preparation according to the proportion fixed. The beer scales (areometers) are also useless, because beer is a mixed liquid, and it is impossible to construct an instrument to be used at the same time for light and heavy liquids. Among the different chemical method of investigation, that of Professor Tuchs, of Munich, is decidedly the best both on account of its certainty and facility of execution. It is called the hallymetric beer-proof, because culinary salt is the chief agent for testing, and an instrument called hallymeter, is employed. The process is based on the constant solubility of salt in water, and on the peculiarity in the extract of beer, of yielding all its water to the salt. Tuchs has found by numerous experiments, that water dissolves at a temperature from 0° to + 32° R. 36 per cent. of pure muriate of soda. He also found, that the extracts of hops and malt dissolved in beer, yielded all their water to the salt, and only alcohol retains a certain quantity of water. This quantity was also determined by further experiments; Steinheil invented an index, which distinctly indicates the proportions of alcohol and water, contained in the spirit of wine. The hallymetrical analysis of beer is divided into two processes; the first determines the quantity of the whole alcohol, extract and carbonic acid included, and that of free water; the second process fixes the quantity of the extract. (The detailed proceeding of Tuchs may be found in Kunst-u-geverbeblatt d. polytechn. Ver. f. d. K. Baiern vom T. 1836, page 671-709.) This method is of course, only applicable to fix the strength of the beer, but not to determine any adulterations, which may be present, and which must be found out by a more complicated chemical analysis.—*F. Strehler, of Ingolstadt in badische Annalen.*

Zinc and its Preparations considered in a Medico-legal point of view.—The first question is: (*a*) *May oxide and sulphate of zinc become injurious to health?* In answer, the author details Orfila's experiments on dogs, and a series of cases of poisoning in men, which show the possibility of injury by the above substances. (*b*) *May metallic zinc be injurious to health?* The observations collected in France and Prussia, show that the easy oxydation of zinc causes it to be noxious. Its mere continuous contact with air is sufficient to oxydize it; in contact with water (unless purely distilled), oxydation takes place still more rapidly, and the weakest acid will transform it into a soluble salt. Devaux's and Dejaer's experiments which are intended to prove the harmlessness of zinc employed for vessels, are not at all convincing, and show, on the contrary, that zinc dissolved in food or beverages, certainly exerts an injurious influence on the human organism. (*c*) *Other combinations of zinc, as hydrocyanate and muriate of zinc, are violent and energetic poisons.* For the chemical analysis of inorganic and organic substances, suspected to contain zinc, the author details the processes used in the latest researches.—*Dr. Löffler in Magaz. f. d. Staadsarzneik.*

Division of the Thoracic Duct.—The duct began as usual on the first lumbar vertebra, and proceeded upwards to the eleventh thoracic vertebra. Here it gave off a branch larger than the duct itself, which ran along in front of the thoracic aorta, then passed behind it over the eleventh and tenth vertebræ, wound itself round the vena azygos, and opened at a right angle into the thoracic duct. —*Professor Svitzer in Müller's Archiv.*

PROGRESS OF ENGLISH, ITALIAN, AND AMERICAN MEDICAL SCIENCE.

[The following are the only articles of interest to the profession in the last number but one of the *Lancet.*]

ULCERS.—Dr. Cutler explains the non-healing of ulcers consequent on local injuries among the poorer classes of society, by the unhealthy condition of the blood. He says all parts that suffer a solution of continuity inflame, and if the blood is healthy, lymph is separated from the vessels, and is deposited on the surface, which becomes organised by vessels shooting into it. Layer after layer is thus produced, which undergo the same change, till the part made whole. When, however, the blood is vitiated, the process is altogether different. Instead of lymph being formed, there is a secretion essentially distinct from lymph, into which vessels cannot form. Nutrition becomes imperfect or altogether checked, and the parts in the immediate vicinity of the abraded surface become removed by absorption, or if this be also checked, the parts die, and the substance is thrown off in the form of slough. Ulcers that arise without any apparent cause may be produced in this way; and when such is the case, is it erroneous to presume that they are for the purpose of renovating the blood, and so rendering it fitter for healthy nutrition? This, however, more especially occurs when other secreting organs, as the kidneys, liver, &c., are inactive, and do not remove their usual quantity of deleterious matters. He therefore regards the constant draining of the system, by the discharge from the ulcer as being absolutely essential to health. His views, which are merely a revival of the old doctrines of humoral pathology, are to a certain extent correct, and may be usefully applied in practice, in the treatment of these and some other diseases, shewing the advantage of forming an artificial ulcer, as a drain for the system. The utility of a permanent issue is much overlooked by the practitioners of this country.

PROTRACTED LABOUR.—Dr. J. H. Davis narrates a case of protracted labour, in which he performed craniotomy. The removal of the placenta was followed by internal hemorrhage and collapse, which was treated by pressure and stimulants, and afterwards by morphia.

PLEURO-PNEUMONIA AND EMPHYEMA.—A man was admitted into the Westminster Hospital, under Dr. Basham, with symptoms of pleuro-pneumonia, for which he was bled and blistered, and had calomel, opium, and antimony, internally. The treatment was not followed by improvement, and on the fifth day after admission, the respiration was hurried and abdominal, and there were urgent paroxysms of dyspnœa. The left side at the level of the nipple was half an inch larger in circumference than the right; the cough accompanied by a peculiar gurgling sound. The pulse was 100, very feeble and weak. There was a swelling in the left axilla, accompanied by a remarkable flattening of the subclavicular space. The axilla presented an erysipelatous blush. In a few hours' time the left side from the axilla downwards, was œdematous, the spaces between the ribs being obliterated, and the skin retaining a deep impression of the stethoscope. The expectoration was diminished, less viscid, very fœtid, and muco-purulent; pulse 110, small, respiration abdominal; no rising of the sternum during inspiration; severe dyspnœa on motion; countenance anxious. The man died a few days after, and the body was examined thirty hours after death. The left side of the thorax was alone œdematous, and pitted easily on pressure; the convexity and circumference of this side were greater than on the right. On raising the sternum the right lung collapsed, and exhibited the ordinary healthy aspect—a mottled bluish ash-grey. Posteriorly, and towards the apex, were one or two very fine threads of lymph; the pleural cavity contained about a tea-cupful of clear, amber-coloured serum. The pleura costalis of the left side, immediately

below the section of the cartilages of the ribs, was dense and fibrinous, and presented some resistance to the knife before the left pulmonary cavity could be opened. The pleural sac of this side was filled with a fœtid sero-purulent fluid, of a dirty ochre-colour, and in quantity equalling the entire capacity of the left side. The pleura costalis and pulmonalis, which were from three to four lines in thickness, were covered severally with a film of tenacious dirty-green gangrenous fibrin. The left lung, by the pressure of this vast quantity of fluid, had become compressed against the mediastinum, into a magnitude not exceeding the size of a turkey's egg. The parenchyma, or substance of this lung, when cut into, was bloodless, and presented an appearance such as would result from mere mechanical pressure supposed to be exerted gradually, and to be equal on all sides. The pleura-pulmonalis was much thickened, and very dense and carnified in structure, with a gangrenous layer of lymph. The mucous membrane of the bronchi of this side, so far as it could be traced, was of a dirty, rusty hue, and covered with a tenacious secretion. The air passages of the right side were injected, and also coated with a mucous secretion. The liver was much enlarged, and in the early stage of cirrhosis. The other viscera were comparatively healthy. Dr. Basham in some observations on this case, with reference to the propriety of performing paracentesis thoracis, observed, that the operation could not in this case be justifiably performed so long as the urgent inflammatory symptoms remained unmitigated. If these symptoms had abated, if the patient had exhibited any indications of the vital powers even continuing the struggle, and battling on with the left side filled with pus, he should instantly have recommended the operation; but with rapidly failing powers, and with symptoms that from the first had not been in the slightest degree arrested or ameliorated, such an operation would have been most injudicious. It would have been neglecting (or at least attaching no value to) those unerring characters of a rapidly sinking state which this patient palpably exhibited; and it would, by its failure, have tended to throw discredit on a highly beneficial operation when directed with judgment, and employed in cases where the powers of life were still comparatively vigorous, and where the serous or purulent accumulation was rather the source of remote than immediate hazard. Had the operation been performed in this case, the patient would not the less have continued to sink, for the outlet of so much fluid could not have arrested the destructive disorganisation and gangrene of the pleura. As a general rule, this operation should be postponed till the more acute inflammatory symptoms have subsided, and then care should be taken to determine the presence of any organic lesions of the lungs; for if the lungs be diseased, the prospects of success are rendered both remote and doubtful.

Rupture of the Uterus; Gastrotomy.—Mr. Jackson narrates in the *Provincial Medical Journal*, the particulars of a case of rupture of the uterus, which occurred in a patient, twenty-six years of age, while under the care of a midwife. The woman was the mother of three children, and her former labours had been severe and protracted. The rupture took place about four, p. m., and an hour afterwards, when Messrs. Jackson and Clarke saw the patient, no presentation could be felt; the vagina was filled with coagulated blood, and the fœtus could be felt through the abdominal parietes, having escaped into the peritoneal cavity. The woman's state was very alarming, and there was great restlessness and anxiety. Gastrotomy was decided on for the removal of the child, as it was considered that its extraction by the uterus and through the pelvis would be likely to inflict additional injury, and exhaust the feeble powers of life. As a necessarily preliminary step, the urine was drawn off, and the patient was placed in a convenient position, on her back on the bed. The integuments of the abdomen being kept on the stretch by an assistant, an incision of about six or seven inches was made with a scalpel, extending from two inches above the pelvis, to a short distance of the umbilicus. The peritoneum having been laid bare, an opening was made, and that membrane divided co-extensively with the external wound. The omentum then protruded, which being carefully held on one side, a tense bag containing a yellow fluid presented itself, being in fact the ordinary membranous envelope of the fœtus in utero. The contents, consisting of the liquor amnii, together with a large quantity of coagulated blood, were evacuated by a puncture, and the head of the child presented itself. The fœtus was extracted by the feet, and it was found that the external wound was barely sufficient to allow of the passage of its head. The placenta had been expelled from the uterine cavity, and was lying amongst the intestines, together with a considerable quantity of fluid and coagulated blood, all of which was removed. The time occupied in the performance of this operation was not more than a few minutes, and during its continuance, the patient, although perfectly conscious, remained quite tranquil. The omentum and intestines protruded from the wound, but were easily replaced, whilst the edges of the wound were brought together by sutures, and strips of adhesive plaster, and a firm bandage completed the dressing; after which the patient was placed in a favourable position. The poor woman bore the operation with great fortitude, and expressed herself as being very much relieved, and considered that she had terminated her labour with much less suffering than she had experienced on former occasions. The pulse almost immediately rallied, and the appearances of extreme exhaustion subsided. The child—a female—was considerably above the middle size, weighing eleven pounds and a quarter, and had no doubt ceased to exist at the period of the accident. Wine and a full opiate were given, and she was left in a composed state under the charge of an experienced nurse, who had instructions to administer nutritious fluids, and if needful, more wine. The patient survived the operation a few days only, dying of exhaustion and low fever. Prior to death, the wound in the abdominal parietes had united generally, excepting at some points, whence there issued a slight purulent discharge. At the examination of the body it was found that the divided abdominal peritoneum had become adherent along the wound to the subjacent parts, on breaking down which, and separating the edges of the wound, a little purulent matter was discovered. The convolutions of the intestines and the omentum were, in several places, slightly adherent by lymphatic effusion, and this condition prevailed in several places between the contiguous surfaces of the serous membrane. The general peritoneal surface exhibited a slight state of vascularity, and this condition was more conspicuous in the neighbourhood of the uterus, which viscus was slightly adherent to the bladder. Four ounces of a dark-brown fluid were effused into the cavity of the peritoneum, but not at all intermixed with pus. The omentum presented throughout its extent a brown colour; but there was no gangrenous appearance in this or any other part. The stomach was healthy, and very slight vascularity was observed on its outer coat. The uterus had contracted to the size to which it is usually reduced about the seventh day after delivery. It presented a perfectly normal appearance, excepting a slightly increased vascularity, and felt firm in its general structure. Its outer covering, as before stated, was slightly adherent to the contiguous peritoneal surface. Upon raising up this organ towards the pubes, a dark-brown ragged opening was discovered, chiefly seated in the posterior wall of the vagina, and apparently extending through a small portion of the cervix uteri. The length of this opening varied according, as it was enlarged by stretching, or suffered to remain in its original state with the parts *in situ*. The variation of the laceration was thus from three to five inches. Besides this longitudinal laceration, there was a considerable transverse division just at the point where the vagina joins the cervix. There had been no attempt to close this lacerated wound by any reparative process; but the contiguous surfaces of the peritoneum had become so generally adherent as effectually to prevent the secretions or discharges from the uterus or vagina from passing into the abdominal cavity. The edges of the lacerated opening were irregular, jagged, and of a dark-brown colour, but free from any gangrenous state. The inner surface of the organ presented nothing unusual in its appearance. The pelvis, although apparently well-formed, was slightly under the natural dimensions in its antero-posterior admeasurement, and, considered in connection with the large size of the fœtus (eleven and a quarter pounds) was decidedly disproportioned.

CASE OF CEPHALHŒMATOMA.

By A. W. Close, Esq., Manchester.

In the month of November, 1844, I was requested to see the infant of the Rev. Mr. B——, residing at a village near Huddersfield. On either side of the sagittal suture, and about the centre of each parietal bone, was a tumour—that on the right being much the larger. "These tumours," says the father, "were discovered the day after birth, and were shown to the medical attendant. The child was nineteen days old when you saw it, and the only means used was the mildest of the three recommended by yourself, viz., some folds of linen sewn into the top of the cap. They disappeared about five weeks after you saw the child, the bone gradually closing in, or rather growing, and the swelling subsiding as the bone closed." Such is the father's description of the condition, progress, and issue of the case.

Naegelé has described these tumours under the term "cephalhœmatoma." They are found occupying different localities, and consist of sanguineous fluid effused either under the bone, under the pericranium, or under the aponeurosis of the occipito-frontalis.

The existence of the first variety—the subcranial—is accompanied by symptoms of cerebral compression. When these are present, together with an external cephalhœmatoma, it may be suspected.

That wherein the blood is effused under the aponeurosis is the consequence of external violence after birth.

The foregoing case is an instance of the kind, wherein the effusion takes place between the pericranium and the bone. The chief diagnostic symptom is the presence of a distinct bony ridge surrounding the tumour, which gives the impression that there is a cavity in the skull. The bone can generally be felt within the circle, continuous with it, but apparently depressed below it; but in this case I could not detect it by using any reasonable degree of pressure. These tumours can always be detected from encephalocele by the absence of pulsation, by the situation they occupy, occurring in all cases, with which I am acquainted, about the centre of the parietal bone, generally of the right side. Encephalocele usually occupies the site of a fontanelle or suture; is circumscribed, globose, and of cerebral density. A case, I observe, is reported in the *Medical Times* of October 26, 1844, under the observation of Velpeau, where the hernia occupied a congenital opening of the bone, immediately below the occipital protuberance.

The cause of this kind of tumour was conjectured by Haller. He noticed, on compressing the head of an infant, even slightly, after removing the pericranium, drops of blood springing from between the radiated fibres of the parietal bone. Dubois corroborates Haller's experiment, and suggests it as an explanation of the formation of cephalhœmatoma. It has been further confirmed by M. Valleix, who concludes, that if circular pressure be made upon a point of the cranium, blood will spring from the surface of the bone, and the pericranium in the fœtus being but loosely attached, becomes detached to a considerable extent and forms the cyst of the tumour. Dr. Valleix's explanation seems very probable, as this tumour is never met with but after protracted or rapid labour; in the one case there being the evil of long-continued, in the other of violent and unduly augmented pressure.

It is stated by some of our journalists that these tumours have scarcely been mentioned by British obstetricians or pathologists. This is a mistake. In an original MS. of the late Dr. W. Hunter, published some twelve or fifteen years ago, the following distinct allusion will be found:—"In many children, a few hours after birth, a large soft tumour appears on the head, commonly a little to one side of the very top of the head; it is formed by blood. Frequently there seems to be an edge of the skull

all around, as if there were a large perforation, or want of bone at the place, but this is a deception; some very good surgeons make it a rule to open it, but this is cruelty, for there is never occasion. The child's health is never hurt by it, and it always goes away by itself; generally within the month, sometimes later, and for the most part continues without diminishing to very near the last, then it begins to be sensibly a little softer, like a bag of fluid that is a little emptied, after which it disappears very fast. I have never seen one case that did not do well of itself, not even among 12,000 children that have been born at the British Hospital, which I have attended since its institution; at first I tried many discutient applications, but I soon found that they were both useless and unnecessary"

It may be supposed that Dr. H. here alludes to that intumescence of the scalp which so frequently occurs, known as the caput succedaneum; but he mentions the "edge of the skull" with the apparent perforation, which are the striking peculiarities of the sub-pericranial variety.

The principle of treatment to be kept in view is the excitement of the absorbents. We may judge of the power of assimilation and absorption in infancy, by the fact that a child nearly doubles its weight in a few months from the time of its birth. Various discutient lotions are used, but simple pressure by means of a piece of tin-foil, or a compress of linen adjusted to the cap, or adhesive strappings, is all that is necessary. When these fail, the evacuation of the tumour by the subcutaneous incision may be judiciously adopted.

The chief valuable deduction of a practical nature to be drawn from the foregoing remarks is, that of being able to prognosticate the successful issue of such cases. The experience of Dr. Wm. Hunter, and of other medical authorities, warrants such expectation. The mind of the parents is greatly relieved by such information. Mr. B., in his letter to me, says, "I shall not soon forget the relief afforded me by your information." The feelings of the surgeon are no less gratified by a correct diagnosis, as it certainly is a much less formidable and troublesome affection than encephalocele.

Grosvenor-street, Sept. 6th, 1845.

NOTICES TO CORRESPONDENTS.

A HANDSOME PORTFOLIO *for holding the* "MEDICAL TIMES"—*very desirable to those who would keep the numbers clean for binding, and easy of reference—may be had, by order of any Bookseller, or at the Office, price 5s. An allowance is made to the trade.*

☞ ☞.—*Several subscribers, in arrears, are requested to forward immediately the amount of their accounts, in order that their names may not be placed in our list of defaulters.*

S. N., Cambridge.—*The remedy mentioned is an old one, and has been used before in cases of inflammation, though not, we think, in the large doses recommended by our correspondent. Should S. N. feel disposed to send us some remarks on the subject, illustrated by cases, and authenticated by his name and address, we shall probably give them insertion.*

C. A., Portsmouth.—*A letter addressed to Mr. Gower, Hampstead, will reach its destination.*

We cannot understand why Mr. Thompson, of Ripon, *does not receive his papers regularly. All our papers to* direct *subscribers are invariably posted* together *in time for Friday evening's mail, and ought to be delivered on Saturday morning. We think the delay must occur in the local post-office. Do the papers appear to have been opened?*

A Young Student.—*The* Medical Times *is published regularly at six o'clock every Friday morning, and forwarded to country subscribers by the Friday evening's post. We presume our correspondent does not receive his papers direct from the office.*

A General Practitioner and Subscriber for many Years *has addressed us a letter on the subject of the insurance office grievance. We believe that medical men hold considerable power in their own hands for the abatement of this injustice. The question seems to be this:—an insurance company pays its own officer for examining the applicant, but to make assurance doubly sure, applies also to the usual medical attendant for an opinion on the habitual state of health. Now this is evidently a service for which the surgeon should be paid, and as his opportunities of information must be ample and of much importance to the company, he naturally looks to it for payment. Information of equal value cannot be obtained elsewhere; and in case the usual honorarium be refused, we recommend a refusal of the information asked. This we think will soon produce the desired effect.*

P. M. Cooke, Enniscorthy.—*Mr. Clendon's forceps may be procured of Evrard, 35, Charles-street, Middlesex Hospital. The prices vary from 9s. to 11s. each, and of course the cost of the set will depend on its completeness. We can give our correspondent no information respecting the probable charge for carriage.*

In consequence of the fulness of our index—a great convenience to subscribers who have the volumes bound for reference—we are unable to complete it in the present number. We, therefore, propose to publish the remainder in our next, which will thus contain an extra quantity of matter.

The MEDICAL TIMES is the only Medical Journal published at its own Office, and which is free from the control of all Booksellers and Publishers. Gentlemen may procure it by an order on any Newsman or Bookseller, or it will be sent direct from the Office of the Medical Times to Annual Subscribers sending One Guinea IN ADVANCE, which will free them for twelve months. Half-Yearly Subscription, 13s.; Quarterly, 6s. 6d. The Pharmaceutical Number is published once a month, as an extra number; the subscription is 6s. per annum. No number of the Medical Times can be forwarded, except to gentlemen paying in advance.

THE MEDICAL TIMES.

SATURDAY, SEPTEMBER 20TH, 1845.

Te maris et terræ numeroque carentis arenæ
Mensorem cohibent, Archyta;
Pulveris exigui prope littus parva Matinum
Munera; nec quidquam tibi prodest
Aerias tentâsse domos, animoque rotundum
Percurrisse polum, morituro!

EVERY good has its evil, and as if the greatest social boon of our epoch—railroad locomotion—was not to be exempt from the common lot, it is said to have a tendency to cause apoplexy. The accusation is the most telling that could be well made; for the great recommendation of railways being that they save time, what more effective contradiction than that they shorten life? The importance most men attach to a doubt on such a subject may well excuse from us a few observations.

It is known familiarly that hereditary predisposition, or, in other words, a constitutional state of the system distinguished by plethora, flushed countenance, sanguineous temperament, short neck, &c., is one of the most common causes of apoplexy. To this may be added, free living, with abundant use of excitants, such as spirituous liquors, excesses in diet, irregularity in the alvine evacuations, excitement, violent emotions of any kind, diseased state of the circulating system, such as hypertrophy of the heart, and so on. These causes, varied as they may be, produce their effect only in one way—by *inducing an irregular state of the circulation.* In many instances premonitory symptoms occur, such as giddiness, noise in the ears, a sense of fulness in the head, flushing of the countenance, injection of the eyes—symptoms which depend, with apoplexy itself, on an irregular distribution of blood. The proximate cause of the fit is in general a rupture of some vessel within the cranial cavity, and consequent effusion of blood, though this is by no means necessary to produce even a fatal result; for it stands proved by dissection that apoplexy may occur simply from a congested state of the vessels of the brain, without rupture, just as much as faintness may ensue from a deficient supply of vital fluid to this organ.

With this brief description of the nature of apoplexy, we are brought to the question—is it possible for rapid motion to induce apoplexy, or, more simply still, to produce any very disturbing effect on the circulation? We for the present pass over the results arising from the *direct* mechanical action of motion on the circulating fluids of the body. They are enveloped in more doubt and obscurity than any other fact perhaps connected with hydrostatics, whence probably we may be too disposed to underrate their possible importance. It is not requisite, however, to expatiate on this untrodden ground, and we proceed to deal with the actual proved physical effects universally recognised as concomitants of rapid motion.

Most persons have experienced, at some period of their life, a peculiar dizziness and sickness at the stomach, while travelling in a closed carriage of any kind—a dizziness increased when the back has been towards the horses. These unpleasant sensations have been the more acutely felt when the attention has been fixed on the objects passed. On what must this *morbid* state of sensation depend? The reply is evident: on some disordered action or slight irregularity of circulation in the brain, produced among, perhaps, *other* agencies, by the unaccustomed effect on our senses of viewing the objects around us in apparently rapid motion. It must not be supposed to be any peculiarity in the construction of the carriage. We observe the same effects in the youth swung in the merry-go-round of the fair, the landsman first voyaging on sea, and it indeed seems to be a law that rapid motion, and, more or less, constitutional disturbance, always go together, till custom habituate the economy to a new order of things. But though, in most instances, by becoming accustomed to the action, we lose this unpleasant sensation, there are persons (chiefly delicate females) in whom this state of suffering cannot be overcome, and in whom it progresses from simple dizziness to actual faintness. Now, in these cases it is impossible to deny the existence of some irregularity of the circulation, whether from original debility affecting the system generally, or the vascular, or cerebral system especially, is unimportant to the subject under consideration. It may be objected that this faintness is a very different condition to the congestion preceding apoplexy; but this distinction is here of no importance, for all we seek to establish is, that an irregularity of circulation may be produced; and it is allowed that a cause—sudden excitement, for instance—which would produce faintness in a delicate female, may cause congestion in a person whose system is in a state predisposing him to its occurrence. In addition to this cerebral effect arising from motion—an effect likely to be experienced with greater intensity in railway travelling, because the exciting cause is proportionably more powerful—let us pay a moment's thought to the noise of a train at full speed, the frightful scream of the whistle, the close and contaminated atmosphere of the tunnels, with the excitement produced by the thousand circumstances ever connected with travelling, but centupled in connexion with this especial kind of locomotion. Without dwelling on the possible state of mental emotion, or the atmospheric condition, so remarkably different within the vehicle and without, we have three organs of sensation assailed at once—the eyes, by the apparent motion in external objects,

the ears, by the confused and confusing din around, the touch by the jostle and oscillation of rapid movement. Expose a person of an apoplectic habit, after, perhaps, a full meal and excited walk or drive, with the other accompaniments of travelling preparations, to these influences combined, and who can be surprised that the circulating equilibrium is largely interfered with, or that congestion occurs in an organ in most cases very liable to be affected by it? Who can be in wonder that the vessels of the brain, at length becoming congested beyond their utmost capabilities of dilatation, an internal hemorrhage takes place, and the apoplectic stertor announces the occurrence of the too often fatal disease? And let it not be overlooked, that this actual rupture of a vessel is not absolutely necessary; the *congestion* alone, as we have said, is sufficient, in many instances, to produce death.

We are not ignorant of the objection that the guards and stokers of the different railways do not suffer from the disease. But their state of health and nature of previous habits must be taken into consideration. These persons are accustomed to their calling; they are young, vigorous, in the robust health which constant out-of-doors exercise is likely to give: theirs is a regular, ordinary business, free from the excitement of a traveller hurrying impatiently to keep an appointment; and, besides, the brain with them is not that enervated, overtasked, and diseased organ it is with many of the literary, scientific, or mercantile passengers it may be their duty to convey. And it must be recollected that we do not maintain that a *healthy* individual shall succumb, by railway travelling, to an apoplectic seizure, though the brain may be put under increased and trying exercise, its vigorous texture triumphs over the ordeal; and, we have before stated, that the giddiness accompanying rapid locomotion, in other words, the cerebral disturbance, may, in most instances, be overcome by habit. We proceed no further than this, and from that point we will not recede, that railway locomotion is not without serious danger to those predisposed to apoplexy. And if any one of our readers still disbelieve or doubt the disturbing action of rapid motion on the brain, let him, the next opportunity, fix his eyes on the opposite line of rails while the train is proceeding at full speed, and we venture to predict that his sensations will not leave him long incredulous.

We need not say that we advance these views out of no anxiety to assume the unloved *rôle* of alarmists. Railway locomotion is an established fact, and no extent or force of argumentation, and no collateral amount of individual mischief, can ever impede its universal adoption. But if the fact be as we have stated—and too many victims, alas! have recently tended to demonstrate our physiological inductions—there can be no good end answered by hiding it, and much benefit may arise from its wide promulgation. The predisposition to apoplexy, which alone makes railway travelling dangerous, may be overcome by good constitutional *training*, if we may be allowed that expressive word. The brain—which, in the cerebral activity superinduced by the progress and conflicts of society, is more maltreated by us than any other organ of the body—*is to a great extent under our own command, for both disease and health* and in the very proportion that rapid locomotion is a necessity, in that proportion is there a necessity for our maintaining the animal organism in a fit state for its safe endurance. The laws of physiology, though little known, are eternal, and, though little obeyed, are never broken with impunity. Fortunate is it for us, therefore, that each new trophy of man's mental power, subduing to him marvellously mechanical forces of more than giant efficacy, creates but a fresh necessity for the careful study and guidance of his own animal machine, and let us hope that our magical advance in locomotive science—the fruit of mental *activity*—will promote largely a knowledge and observance of the laws that should govern that activity, and thus repay us the physical benefit of its creation by a moral benefit not less vast or acceptable.

MEDICAL MECHANICAL INVENTIONS.

Practitioners who are for the most part engaged in the treatment of acute diseases, too pay little attention to those minutiæ of comfort, by which the sufferings of patients afflicted with chronic and tedious ailments may often be so much ameliorated. In the constant practice of the more arduous duties of the profession, they are compelled to give their time and attention to cases which demand immediate care, and consequently leave the less important duties of attention to comfort in some diseases, always tedious from their duration even when ultimately capable of cure, to the patient's relatives or hired attendants. Daily themselves engaged in active employment, they forget the *ennui* and irritability of the system caused by long confinement, that in many cases very considerably aggravate the original complaint. In cases of spinal disease, in which the patient is constrained to maintain for months a recumbent position, in affections of the head where stooping is prejudicial, and in the numerous class of diseases of the chest, the patients are often during their long confinement debarred the only solace of the sick, that of mental employment. In the majority of these cases to read is most fatiguing, if not impossible, from the difficulty of sustaining the book in a proper position; and debarred from this amusement, who will say that time does not pass wearily? It is chiefly on account of the sick that we hail with pleasure an invention expressly for their comfort, named *the Patent Reading Easel*, which we are convinced will soon be in general use, and of great service to invalids of all classes. The invention is most simple and portable, and can be fixed on any couch, bed, or chair, and removed in an instant without injury to the furniture. It can be arranged at any required focal distance, and will on this account, we imagine, be of much service to the apparently increasing class of persons suffering from myopia. We are always glad to notice inventions tending to the comfort of invalids, and having experienced the depressing effects of confinement without occupation, we regard the *aid* at present before us, although extremely simple, as being pre-eminently useful.

MR. THOMAS WAKLEY.

The statement in our journal on this gentleman's illness has been contradicted with various degrees of positiveness. We made our announcement on good authority, and we still believe it is substantially true. We have since had our attention directed to the *Railway Bell*, in which several days before a similar statement was published, and on enquiry, the proprietor of that journal has assured us that he can vouch for the accuracy of the statement. It has been said that Mr. Mills has *pretensions* to be a medical man. The only question for us is—what are his *qualifications*?

We are glad to perceive a long report of medical proceedings in the *Norwich Mercury*. A museum has been lately opened in that town through the liberality of Mr. Dalrymple, with many very valuable additions from the pathological stores of Mr. Crosse. The room was erected by public subscription, and fitted up under the care of a committee of the governors of the hospital. This is a step in the right direction which will raise still higher the fame of the Norwich Hospital staff and profession generally in that locality.

GOSSIP.

Apothecaries' Hall.—Admitted Licentiate on the 12th of September, 1845:—George James Macklin.

Baths in Liverpool.—We have received the most flattering account of the success of the baths in Frederick-street, Liverpool, under the patronage of the corporation. The washing department does not appear to have answered so well. The charges for the baths are 1d., 2d., 3d., 4d., 6d., and 1s., according to the times and convenience. They are both cold and hot. The receipts, first year, in the bathing department, were £118 11s. 4d.; second year, £229 16s. 6d.; third year, £279 17s. 6d.; and for three months this year, from May to August, £118 16s. 3d., being a very large increase. In Bolton we find that the different societies are coming out to support the men's bath about to be erected. The "Harbour of Rest" lodge of Independent Odd Fellows has agreed to subscribe £10, and the "David's Tent" lodge of Rechabites, £10.—*Preston Guardian.*

The late Midwifery Case on Saffron-hill.—Sir,—Can you inform me why Dr. Davis was substituted for Dr. Waller in making the post-mortem examination in this case? My reason for asking this question is not that I think a physician a more proper person to make a post-mortem examination than either of the respectable surgeons who attended the poor woman, but because Dr. Waller was called to see her previously to her death; and one would have thought, therefore, that he would have been selected, provided an M.D. had been required. In a late number of the *Lancet* a case is related in which the surgeon in attendance reflects somewhat harshly on conduct of a similar nature, and which he ascribes to the want of proper understanding on the part of a *non*-medical coroner. He will perceive, however, that even the champion of medical coroners can act in the same way when it answers his purpose, and therefore it is not an error peculiar to the lawyer. By-the-bye, the coroner for Middlesex seems as versatile in the selection of his post-mortem examiners, as in all his other doings. Some time since he could not hold an inquest without ——, and now it is always ——. By the admission of the communication alluded to, Mr. Wakley virtually admits the sentiments of his correspondent, which strongly condemns the practice he himself adopts; he must therefore conclude that what is very wrong in a lawyer, is nevertheless right in a medical man.—A Constant Reader.

MORTALITY TABLE,

For the week ending September 6, 1845.

Causes of Death.	Total.	Average of 5 summers	Average of 5 years
All Causes	840	904	963

CLOUDS.—Against much rain the clouds grow bigger and increase very fast, especially before thunder.—When the clouds are formed like fleeces, but dense in the middle, and bright toward the edges, with the sky bright, they are signs of a frost, with hail, snow or rain.—If clouds breed high in air, in thin white trains, like locks of wool, they portend wind, and probably rain.—When a general cloudiness covers the sky, and small black fragments of clouds fly underneath, they are a sure sign of rain, and probably it will be lasting. Two currents of clouds always portend rain, and, in summer, thunder.——WIND.—If the wind veers about, much rain is pretty sure. If in changing it follows the course of the sun, it brings fair weather; the contrary, foul.—Whistling, or howling of the wind, a sure sign of rain.——METEORS.—The Aurora Borealis, after warm days, are generally succeeded by cooler air.—Shooting stars are supposed to indicate rain.

Universities, Colleges, Hospitals, Schools of Medicine, &c.

ENGLAND.

UNIVERSITY OF LONDON, SOMERSET HOUSE (1837).

Chancellor, the Earl of Burlington, L.L.D., F.R.S.
Vice-Chancellor, J. G. S. Lefevre, Esq., M.A., F.R.S.
Registrar, R. W. Rothman, M.A., M.D.
Clerk to the Senate, Mr. H. Moore.

Examiners.—Faculty of Medicine. Intellectual Philosophy, Logic, and Moral Philosophy: Rev. Henry Alford, M.A.; T. B. Burcham, Esq., M.A. Medicine: Arch. Billing, M.D.; Alex. Tweedie, M.D., F.R.S. Surgery: John Bacot, Esq.; Sir Stephen L. Hammick, Bart. Anatomy and physiology: Francis Kiernan, Esq., F.R.S.; Professor Sharpey, M.D., F.R.S. Physiology and Comparative Anatomy: Professor Rymer Jones. Midwifery: Edward Rigby, M.D. Chemistry: W. Thos. Brande, Esq., F.R.S. Botany: Rev. Professor Henslow, M.A. Materia Medica and Pharmacy: Jonathan Pereira, M.D., F.R.S.

Examinations for the Degree of Bachelor of Medicine.—Candidates for the degree of bachelor of medicine are required, 1. To have been engaged during four years in their professional studies at one or more of the institutions or schools recognised by this university. 2. To have spent, one year, at least, of the four, in one or more of the recognised institutions or schools in the United Kingdom. 3. To pass two examinations.

The first examination takes place once a year, and commences on the first Monday in August. No candidate is admitted to this examination unless he produces certificates to the following effect:—1. Of having completed his nineteenth year. 2. Of having taken a degree in arts in this university, or in a university the degrees granted by which are recognised by the senate of this university; or of having passed the matriculation examination. 3. Of having been a student during two years at one or more of the medical institutions or schools recognised by this university, subsequently to having taken a degree in arts, or passed the matriculation examination. 4. Of having attended a course of lectures on each of four of the subjects in the following list:—descriptive and surgical anatomy, general anatomy and physiology, comparative anatomy, pathological anatomy, chemistry, botany, materia medica and pharmacy, general pathology, general therapeutics, forensic medicine, hygiene, midwifery and diseases peculiar to women and infants, surgery, medicine. 5. Of having dissected during nine months. 6. Of having attended a course of practical chemistry, comprehending practical exercises in conducting the more important processes of general and pharmaceutical chemistry; in applying tests for discovering the adulteration of articles of the materia medica, and the presence and nature of poisons; and in the examination of mineral waters, animal secretions, urinary deposits, calculi, &c. 7. Of having attended to practical pharmacy during a sufficient length of time to enable him to acquire a practical knowledge in the preparation of medicines. These certificates must be transmitted to the registrar at least fourteen days before the examination begins. The fee is five pounds.

Candidates are examined in anatomy, physiology, chemistry, botany, materia medica, and pharmacy.

Examination for Honours.—Any candidate who has been placed in the first division at the first examination, may be examined for honours in any or all of the following subjects:—anatomy and physiology, chemistry, materia medica, and pharmaceutical chemistry. The examinations take place in the week following the commencement of the first examination. They are conducted by means of printed papers; but the examiners are not precluded from putting *viva voce* questions upon the written answers of the canditates when they appear to require explanation. If, in the opinion of the examiners, sufficient merit be evinced, the candidate who distinguishes himself the most in anatomy and physiology, or chemistry, materia medica, and pharmaceutical chemistry, will each receive an exhibition of thirty pounds per annum for the next two years, and under the same circumstances, the first and second candidates in each subject will each receive a gold medal of the value of five pounds.

Second Examination.—The second examination takes place once a year, and commences on the first Monday in November. No candidate is admitted to this examination within two academical years of the time of his passing the first examination, nor unless he produces certificates to the following effect:—1. Of having passed the first examination. 2. Of having, subsequently to having passed the first examination, attended a course of lectures on each of two of the subjects comprehended in the list, and for which the candidate did not present certificates at the first examination. 3. Of having, subsequently to having passed the first examination, dissected during six months. 4. Of having conducted at least six labours. (Certificates on this subject will be received from any legally-qualified practitioner in medicine). 5. Of having attended the surgical practice of a recognised hospital or hospitals during twelve months, and lectures on clinical surgery. 6. Of having attended the medical practice of a recognised hospital or hospitals during other twelve months, and lectures on clinical medicine. 7. Of having, subsequently to the completion of his attendance on surgical and medical hospital practice, attended to practical medicine in a recognised hospital, infirmary, or dispensary, during six months. (Certificates on this subject will be received from any legally-qualified practitioner having the care of the poor of a parish). The candidate must also produce a certificate of moral character from a teacher in the last school or institution at which he studied, so far as the teacher's opportunity of knowledge has extended. These certificates must be transmitted to the registrar at least fourteen days before the examination begins. The fee is five pounds.

Candidates are examined in physiology (the papers in physiology include questions in comparative anatomy), general pathology, general therapeutics, hygiene, surgery, medicine, midwifery, and forensic medicine.

Examination for Honours.—Any candidate who has been placed in the first division at the second examination, may be examined for honours in any or all of the following subjects:—physiology and comparative anatomy, surgery, medicine, midwifery, structural and physiological botany. The examinations take place in the week following the second examination. They are conducted by means of printed papers; but the examiners are not precluded from putting viva voce questions upon the written answers of the candidates when they appear to require explanation. If, in the opinion of the examiners, sufficient merit be evinced, the candidate who distinguishes himself the most in physiology and comparative anatomy or surgery, and in medicine, will each receive an exhibition of fifty pounds per annum for the next two years, with the style of University Medical Scholar; and under the same circumstances, the first and second candidates in each of the preceding subjects, will receive a gold medal of the value of five pounds. Under the same circumstances, the candidate who distinguishes himself the most in midwifery, or in structural and physiological botany, will each receive a gold medal of the value of five pounds.

Examination for the Degree of Doctor of Medicine.—The examination for the degree of doctor of medicine commences on the fourth Monday in November. Candidates must produce certificates to the following effect:—1. Of having taken the degree of bachelor of medicine in this university, or a degree in medicine or in surgery, at a university, the degrees granted by which are recognised by the senate of this university. (Those candidates who have not taken the degree in this university must produce a certificate of having completed their twenty-third year). 2. Of having attended, subsequently to having taken one of the above degrees in medicine (*a*), to clinical or practical medicine during two years in a hospital or medical institution recognised by this university; (*b*) or, to clinical or practical medicine during one year in a hospital or medical institution recognised by this university, and of having been engaged during three years in the practice of his profession; (*c*) or, if he have taken the degree of bachelor of medicine in this university, of having been engaged during five years in the practice of his profession. (One year of attendance on clinical or practical medicine, or two of practice, will be dispensed with in the case of those candidates, who, at the second examination, have been placed in the first division). 3. Of moral character, signed by two persons of respectability. The fee is ten pounds.

Candidates are examined in the elements of intellectual philosophy, logic and moral philosophy, and medicine. If sufficient merit be evinced, the authors of the best commentary on the case in medicine, surgery, and midwifery, will each receive a gold medal of the value of five pounds. Any candidate may present a thesis on a subject of his own choice; and, if sufficient merit be evinced, a gold medal of the value of ten pounds will be awarded.

Examination for Honours.—Any candidate who has been placed in the first division may be examined for honours in any or all of the following subjects:—surgery, medicine, midwifery. If sufficient merit be evinced, the first candidate in each subject will receive a gold medal of the value of five pounds.

Regulations relating to Practitioners in Medicine or Surgery desirous of obtaining the Degrees in Medicine.

Degree of Bachelor of Medicine.—Candidates will be admitted to the two examinations for the degree of bachelor of medicine on producing certificates.—1. Of having been admitted, prior to the year 1840, members of one of the legally constituted bodies in the United Kingdom for licensing practitioners in medicine or surgery; or of having served, previously to 1840, as surgeons or assistant-surgeons in her Majesty's Army, Ordnance, or Navy, or in the service of the Honourable the East India Company. 2. Of having received a part of their education at a recognised institution or school, as required by the charter of the university. 3. Of moral character, signed by two persons of respectability. Candidates who have not taken a degree in Arts, or passed the Matriculation Examination in this university, will be required to translate a portion of Celsus *de Re Medicâ*.

Degree of Doctor of Medicine.—Candidates who have been engaged during five years in the practice of their profession will be admitted to the examination for this degree on producing certificates to the following effect:—1. Of having been engaged during five years in the practice of their profession. 2. Of having taken the degree of bachelor of medicine in this university. Candidates who have not taken a degree in arts, or passed the Matriculation Examination in this university, will be required to translate a portion of Celsus *de Re Medicâ*.

UNIVERSITY OF OXFORD.

Chancellor, His Grace the Duke of Wellington, K.G., D.C.L., elected 1834.
High Steward, The Earl of Devon, D.C.L., 1838.
Registrar, Philip Bliss, D.C.L., 1824—Clerk, Mr. G. Purdue.

Regius Professor of Medicine, Tomlins Prælector of Anatomy, Lee's Lecturer on Anatomy, Aldrichian Professor of Anatomy: John Kidd, M.D., 1822.
Sherardian and University Professor of Botany. Aldrichian Professor of Chemistry: C. G. B. Daubeny, M.D., 1834.
Litchfield Professor of Clinical Medicine, Aldrichian Professor of Medicine: J. A. Ogle, M.D., 1830.
Sedleian Professor of Natural Philosophy: G. L. Cooke, B.D., 1810
Savillian Professor of Astronomy: W. F. Donkin, M.A., 1842.
Reader in Experimental Philosophy: R. Walker, M.A., 1839.
Reader in Mineralogy, Reader in Geology: W. Buckland, D.D., 1813-1818.

A candidate for the degree of bachelor in medicine, before he can be admitted to examination for that degree, must have kept four whole years, or sixteen terms, in the university, in like manner as is required by candidates for a degree in arts (that is, he must be of sixteen terms' standing, and have actually *resided* in the university twelve terms); must have passed the examination for the degree of bachelor in arts; and, subsequently to that examination, must have studied medicine during three whole years, or twelve terms; and must also have

completed seven years, or twenty-eight terms, from his matriculation. In testimony of his having fulfilled the above conditions, he is required to produce his matriculation paper, together with the "testamur" of his examination for the degree of bachelor of arts, and the requisite medical certificates.

The medical examination takes place only once in the course of the year—namely, in the second week of full Trinity term, commencing usually on the *second Tuesday* after Trinity Sunday. The candidate is examined, principally "vivâ voce," but partly in writing, in the theory and practice of medicine, in anatomy, physiology, pathology, and materia medica; and also in chemistry and botany, as far as they elucidate the art of medicine. He is required to be conversant with the works of Aretæus and Celsus; the aphorisms and epidemics of Hippocrates; and that portion of Galen's writings, entitled "De usu Partium;" in two, at least, of which authors, the statute directs that the examiners fail not to test his attainments. He must express his intention of being examined, to the regius professor of medicine, full fourteen days before the day of examination, sending at the same time certificates of three years' attendance on the medical practice of some accredited hospital, and on the usual lectures on anatomy, &c. With respect to attendance on lectures, certificates are required for two courses of anatomy and physiology, each course extending through the usual winter session, from October till the following April or May; two courses on the the theory and practice of medicine, each course of the same extent as those of anatomy and physiology; one course in materia medica; one course in botany; one course in chemistry, provided the course extend through the usual winter session, otherwise two courses will be required.

A candidate for the degree of doctor of medicine must have pursued the study of medicine during three years after he has graduated as bachelor in medicine, and must give at least a fortnight's previous notice of his intention to the professor of medicine, at the same time submitting to his approbation a subject for a medical dissertation, which dissertation must be read in the public schools of the university within a few days of taking the degree of M.D., and a fair copy of it delivered to the professor immediately after it has been read. No graduate in medicine from another university can be incorporated at Oxford, unless he produce testimonials by which it may clearly appear that he has kept by residence terms equal to those required to be so kept in this university; has completed all the exercises prescribed by the university, from which he migrates, for the degree of B.A.; has previously undergone the medical examination above described; and has fulfilled all the other conditions of the present statute. The fees for a bachelor of medicine are £23; for a doctor in medicine, £40.

UNIVERSITY OF CAMBRIDGE.

Chancellor, His Grace the Duke of Northumberland, K.G., LL.D., F.R.S., 1840.
High Steward, Lord Lyndhurst, LL.D., 1840.
Registrar, Joseph Romilly, M.A., 1832.
Regius Professor of Physic: John Haviland, M.D., 1817.
Professor of Anatomy: W. Clark M.D., 1817.
Professor of Chemistry: J. Cumming, M.A., F.R.S., 1815.
Professor of Botany: J. S. Henslow, M.A., 1825.
Downing Professor of Medicine: Dr. Fisher, 1841.
Woodwardian Professor of Geology: A. Sedgwick, M.A., F.R.S., 1818.
Professor of Mineralogy: W. H. Miller, M.A., 1832.
Plumian Professor of Astronomy: James Challis, M.A., 1836.
Lowndean Professor of Astronomy: G. Peacock, D.D., F.R.S., 1837.
Jacksonian Professor of Natural and Experimental Philosophy: R. Willis, M.A., F.R.S., 1837.
Curator of the Botanic Garden: A. Biggs, F.L.S.
Curator of the Fitzwilliam Museum: Mr. W. K. Ridgway.

Proceedings in Physic. M.B.—A student before he can become a bachelor of physic, must have entered on his sixth year, computed from the date of his first admission at the university, have resided nine terms, and have passed the previous examination. A bachelor of arts may become a bachelor of physic after having entered on his sixth year, computed from the date of his first admission at the university, provided that one year at least has intervened between his final determination in arts and his admission to the degree of bachelor of physic. The exercises for this degree are one act and one opponency.

Candidates for the degree of bachelor of physic must, previously to the performance of these exercises, in addition to the examination by the regius professor of physic, be examined by the professors of anatomy, chemistry, and botany, and by the Downing professor of medicine. This examination may take place any time in the fifth year after admission, but not earlier. They must have diligently attended the lectures of the regius professor of physic for two terms, and must bring to him certificates of examination by the above professors, and of attendance on their lectures, in case the course of lectures of the professor of botany consist of not less than twenty lectures, and the courses of lectures of the professors of anatomy and chemistry, and of the Downing professor of medicine, of not less than fifty lectures each. They must also deliver to the regius professor of physic, certificates of having been diligently employed in attendance on medical lectures, and the practice of some well-known hospital, for two years, or for as long a time as they have been absent from the university during their undergraduateship. Fee £10 16s.

L.M.—A licence *ad practicandum in medicinâ* may be granted to a bachelor of physic in the term subsequent to that in which he has taken the degree, or to a master of arts of two years' standing. Candidates for a licence *ad practicandum in medicinâ*, being previously bachelors of physic, are required to produce to the regius professor of physic, certificates of their having attended on hospital practice for three years, exclusive of the nine terms which they kept by residence for the degree of bachelor of physic, and of their having attended lectures on the following subjects—namely, practice of physic and pathology, anatomy and physiology, chemistry, botany, medical jurisprudence, materia medica and pharmacy, principles of surgery, principles of midwifery, practical anatomy for two seasons. If the candidate for licence is a bachelor of physic, he cannot be examined for the said licence until the examination which shall occur next but one after his having passed the examination required for the dergee of bachelor of physic. If the candidate is a master of arts, he will be required to bring satisfactory evidence to the regius professor of physic of his having been employed in the study of physic for five years after he became a bachelor of arts; and to produce certificates of his having attended on hospital practice for three of the said five years, and of his having attended lectures on the subjects before mentioned. Every candidate for a licence *ad practicandum in medicinâ* is required to pass an examination to the satisfaction of the regius professor of physic, the professor of anatomy, the Downing professor of medicine, and a doctor of physic to be nominated by the vice-chancellor, and approved by the senate at the first congregation after the 10th of October in each year. There are two such examinations in every year: one in the week immediately preceding that in which the division of the Michaelmas term falls; the other in the week immediately preceding that in which the division of the Easter term falls. Fee £11 6s.

M.D.—The degree of doctor of physic is granted to a bachelor of physic of five years', or to a master of arts of seven years' standing. The exercises are two acts and one opponency.

Every candidate for the degree of doctor of physic, who has not previously obtained a licence *ad practicandum in medicinâ*, is required to produce to the regius professor of physic the same certificates, and pass the same examination, as are required in the case of candidates for a licence *ad practicandum in medicinâ*. Fee £11 12s.

ROYAL COLLEGE OF PHYSICIANS, PALL MALL EAST, LONDON.

President, John Ayrton Paris, M.D.
Treasurer, Dr. Monro.
Censors, Dr. Babington, Dr. Ferguson, Dr. Page, Dr. Budd.
Elects, Dr. Lambe, Dr. Turner, Dr. Hume, Dr. Hue, Dr. Bright, Dr. Monro, and Dr. ——.
Registrar, Dr. F. Hawkins.

Candidates for the licence must be twenty-six years of age, and present a certificate of good moral conduct. The medical certificates must comprise anatomy, the theory and practice of medicine, forensic medicine, chemistry, materia medica, natural history, principally botany, midwifery, and the principles of surgery, attendance upon which for five years is required. Practical medicine must be studied for three years in a hospital containing at least 100 beds, and having a complete staff of physicians and surgeons. Those who have studied abroad, in addition to giving proof of five years' medical education, according to the usual course of study, are required to present testimonials of a twelvemonth's medical practice at any hospital in Great Britain, having the qualifications as above.

Every candidate must undergo three examinations. The first comprises physiology, the second pathology, and the third therapeutics. The candidate is examined in Greek works on medicine, to wit, Hippocrates, Galen, or Aretæus. If the candidate be deficient in Greek, he will be required to translate parts of Celsus or Sydenham, or some other Latin work on medicine, into English. The examinations are conducted in Latin or English, at the pleasure of the censors.

Persons who have attained their fortieth year, seeking to become licentiates of the college, but whose medical education is not altogether in accordance with the regulations already stated, must present testimonials of professional knowledge and good moral conduct; and if these are satisfactory, they will be admitted to examination.

The examinations for the licence are conducted by the president and censors. The periods at which they take place are Michaelmas, Christmas, Easter, and in the month of June.

The college fees are £56 17s for the licence, including the Government stamp of £15; the fellow pays, in addition, £55 1s., including the Government stamp of £25, on his admission. The extra licence costs £17 9s.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, LINCOLNS-INN-FIELDS.

President, Samuel Cooper, Esq.
Vice-presidents. W. Lawrence, B. Travers, Esqs.
Court of Eaminers.—The president, vice-presidents, Robert Keate, J. Painter Vincent, G. J. Guthrie, Anthony White, J. G. Andrews, Sir B. C. Brodie, and E. Stanley, Esq.
Professors: Anatomy and Surgery: John Flint South, Esq.; Hunterian, R. Owen, Esq.; Secretary, Edmund Balfour, Esq.; Conservators, W. Clift, Esq., Professor Owen; Assistant-conservator, J. T. Quekett, Esq.

Bye-laws and Ordinances relating to the Fellowship.

Candidates for the Fellowship.—1. That, except in the cases and instances hereinafter provided for to the contrary, every candidate for the fellowship, whether a member of the college or not, shall produce certificates satisfactory to the court of examiners;—that he is twenty-five years of age, that he is (if found qualified upon his examination) a fit and proper person to be admitted to the fellowship, the certificate of which shall be signed by three fellows; that he possesses a competent knowledge of the Greek, Latin, and French languages, and of the elements of mathematics; that he has been engaged for six years in the acquirement of professional knowledge in recognised hospitals or schools of surgery and medicine within the United Kingdom of Great Britain and Ireland, or in foreign countries; and that three of such years at least have been passed in one or more of such recognised hospitals or schools in London; that he has attended the surgical practice of a recognised hospital or hospitals during four years, and the medical practice of a recognised hospital or hospitals for one year; that he has studied anatomy and physiology by attendance on lectures, and demonstrations and by dissections, during three winter sessions of not less than six months each, at one or more recognised school or schools; that he has attended lectures on the theory and practice

of medicine, and on clinical medicine, and also on the theory and practice of surgery, and on clinical surgery, during two sessions of six months each, at one or more recognised school or schools; that he has attended one course of lectures on each of the following subjects:—viz., chemistry, materia medica, midwifery, medical jurisprudence, and comparative anatomy, at one or more recognised school or schools. And that he has served the office of house-surgeon or dresser in a recognised hospital in the United Kingdom. Every such candidate (except in the cases and instances hereinafter provided for to the contrary) shall also present for examination clinical reports with observations of six or more surgical cases taken by himself at a recognised hospital or hospitals, within the United Kingdom, with sufficient certificates of their authenticity and genuineness, and shall leave such reports at the college.

That, as to any candidate, who shall have taken the degree of bachelor of arts in an English university, and shall produce satisfactory evidence thereof, it shall be sufficient for him to produce a satisfactory certificate or certificates that he has been engaged for five years in the acquirement of professional knowledge in recognised hospitals or schools of surgery and medicine within the United Kingdom, or in foreign countries, and that three of such years at least have been passed in one or more of the recognised hospitals and schools of London; and such candidate is not to produce any certificate of having acquired a competent knowledge of the Greek, Latin, and French languages, and of the elements of mathematics.

Each candidate for the fellowship shall be examined on two days.

The subjects of the first day's examination, anatomy and physiology; of the second, pathology, therapeutics, and surgery.

Regulations of the Council respecting the Professional Education of Candidates for the Diploma of Membership. August 15th, 1843.

I. Candidates will be required, in addition to a certificate of being not less than twenty-one years of age, to bring proof—1. Of having been engaged in the acquirement of professional knowledge for not less than four years; during which period they must have studied practical pharmacy for six months, and have attended one year on the practice of physic, and three years on the practice of surgery, at a recognised hospital or hospitals in the United Kingdom;—three months being allowed for a vacation in each year. (By a resolution of the council on the 7th of November, 1839, no provincial hospital will in future be recognised by this college which contains fewer than 100 patients, and no metropolitan hospital which contains fewer than 150 patients.) 2. Of having studied anatomy and physiology, by attendance on lectures and demonstrations, and by dissections during three winter sessions, of not less than six months each. 3. Of having attended at least two courses of lectures on the principles and practice of surgery, delivered in two distinct periods or seasons; and one course on each of the following subjects—viz., the practice of physic, chemistry, materia medica, and midwifery with practical instruction. Cards of admission to these lectures must be registered at the proper times, in January, April, and October, at the college, or if in the provinces, at the appointed registrars.

II.—Members and licentiates in surgery of any legally-constituted college of surgeons in the United Kingdom, and graduates in surgery of any university requiring residence to obtain degrees, will be admitted for examination on producing their diploma, licence, or degree, together with proofs of being twenty-one years of age, and of having been occupied at least four years in the acquirement of professional knowledge.

III. Graduates in medicine of any legally-constituted college or university requiring residence to obtain degrees, will be admitted for examination on adducing, together with their diploma or degree, proof of having completed the anatomical and surgical education required by the foregoing regulations, either at the school of the university where they have graduated, or at a recognised school or schools in the United Kingdom.

Fee for the diploma, (including stamp) £22; for an articled student (allowed in the diploma fee,) £10 10s; for a certificate of having had the diploma, £5 5s; for being disfranchised, £10 10; a certificate for a surgeon in the Royal Navy, or East India Company's service (allowed in diploma fee), £5 5s; for an assistant-surgeon, £2 2s; for a candidate calling a special court, £5 5s.

The college has in its gift three studentships in anatomy, and once in three years an assistant-surgeoncy in the Army, Navy, and East India Company's service.

THE SOCIETY OF APOTHECARIES, 1815.

Master, John Bacot, Esq.

Wardens, John Ridout, Esq. and Edward Bean, Esq.

The Court of Examiners: Thomas Lowe Wheeler, Chairman. Henry Combe, John Hunter, Edward Tegart, Henry Morley, William Dickinson, Thomas Ansell, Alfred Mayor Randall, William Perrin Brodribb, Charles Smith, Richard Radford Robinson, Robert Norton, Esqs.

Secretary to the Court of Examiners, H. Blatch, Esq.

Clerk, Robert Brotherson Upton, Esq.

Professor of Botany, John Lindley, Ph D., F.R.S.

Superintending Chemical Operator and Professor of Chemistry and Materia Medica, William Thomas Brande, Esq., F.R.S., L. and E.

Chemical Operator, Mr. Robert Warington.

Regulations.—Every candidate will be required to produce testimonials—of having served an apprenticeship of not less than five years to a legally qualified apothecary: (a testimonial of moral character from the gentleman to whom the candidate has been an apprentice, will always be more satisfactory than from any other person.) And of having pursued a course of medical study in conformity with the regulations of the court.

Course of Study.—Every candidate whose attendance on lectures commenced on or after the 1st of October, 1835, must have attended the following lectures and medical practice during not less than three winter and two summer sessions: each winter session to consist of not less than six months, and to commence not sooner than the 1st, nor later than the 15th October; and each summer session to extend from the 1st of May to the 31st of July:—*First winter session:* Chemistry, anatomy, and physiology, anatomical demonstrations, materia medica, and therapeutics; this course may be divided into two parts, of fifty lectures each, one of which may be attended in the summer. *First summer session:* Botany and vegetable physiology, either before or after the first winter session. *Second winter session:* Anatomy and physiology, anatomical demonstrations, dissections, principles and practice of medicine. *Second summer session:* Forensic medicine. *Third winter session:* Dissection, principles and practice of medicine. Midwifery and the diseases of women and children, two courses in separate sessions, subsequently to the termination of the first winter session. Practical midwifery at any time after the conclusion of the first course of midwifery lectures. Medical practice during the full term of eighteen months, from or after the commencement of the second winter session; twelve months at a recognised hospital, and six months at a recognised hospital or dispensary; in connection with the hospital attendance, a course of clinical lectures and instruction in morbid anatomy will be required. The tickets of admission to the lectures and the certificates must be duly registered at the hall, or at the appointed registrars. The latter must be written on a schedule furnished by the society.

The examination of the candidate for a certificate of qualification to practise as an apothecary will be as follows:—In translating portions of the first four books of Celsus de Medicinâ and of the first twenty-three chapters of Gregory's Conspectus Medicinæ Theoreticæ: in physicians' prescriptions, and the pharmacopœia Londinensis: chemistry: materia medica and therapeutics: botany: anatomy and physiology: and the principles and practice of medicine. This branch of the examination embraces an inquiry into the pregnant and puerperal states, and also into the diseases of children. Fee, for London and ten miles around, £10 10s, elsewhere, £6 6s.

The examination of the candidate for a certificate of qualification to act as assistant to an apothecary, in compounding and dispensing medicines, will be as follows: in translating physicians' prescriptions, and the pharmacopœia Londinensis: in pharmacy and materia medica. Fee £2 2s.

SCHOOLS OF MEDICINE IN LONDON.

King's College.—Medicine, one course, £5 5s; perpetual, £7 7s. Surgery, one course, £4 4s; perpetual, £6 6s. Materia Medica and Therapeutics, one course, £5 5s; perpetual, £7 7s. Descriptive and Surgical Anatomy, one course, £8 8s; perpetual, £9 9s. General Anatomy and Physiology, one course, £8 8s; perpetual, £9 9s. Comparative Anatomy, one course, £3 3s; perpetual, £4 4s. Chemistry, one course, £7 7s; perpetual, £10 10s. Practical Chemistry, £5 5s. Midwifery, one course, £4 4s; perpetual, £6 6s. Botany, one course, £3 3s; perpetual, £4 4s. Forensic Medicine, one course, £3 3s; perpetual, £4 4s.

University College.—Medicine, half-term, £3; perpetual, £8. Surgery, one course, £4 10s; perpetual, £6. Materia Medica and Therapeutics, half-term, £3; perpetual, £9. Descriptive and Surgical Anatomy, half-term, £3; perpetual, £9. General Anatomy and Physiology, half-term, £3; perpetual, £9. Comparative Anatomy, one course, £4. Zoology, £3. Chemistry, half-term, £3; perpetual £9. Midwifery, one course, winter, £4 10s; ditto summer, £3; perpetual, £6 10s. Botany, one course, £3; perpetual, £6 Dental Surgery, £1 1s. Forensic Medicine, £4.

Guy's Hospital School.—Medicine, one course, £4 4s: perpetual, £8 8s. Surgery, one course, £3 3s; perpetual, £5 5s. Materia Medica, £4 4s. Descriptive and General Anatomy and Physiology, one course, £5 5s; perpetual, £10 10s. Anatomical Demonstrations, one course, £5 5s; perpetual, 10 10s. Chemistry, one course, £6 6s; perpetual, £8 8s. Practical Chemistry, £2 2s. Midwifery, one course, £3 3s; perpetual, £6 6s. Botany, £3 3s. Forensic Medicine, one course, £3 3s; perpetual, £4 4s. Practical Toxicology, £1 1s. Dental Surgery, £2 2s. Pathological Anatomy, £3 3s.

St. Thomas's Hospital School.—Medicine, one course, £4 4s; perpetual, £6 6s. (Dr. Gregory lectures on the Exanthemata.) Surgery, one course, £3 3s; perpetual, £5 5s. Materia Medica, £4 4s. Ophthalmic Surgery, £2 2s. Descriptive and Surgical Anatomy, one course, £4 4s; perpetual, £9 9s. General Anatomy and Physiology, one course, £5 5s; perpetual, £9 9s. Comparative Anatomy, £2 2s. Chemistry and Practical Chemistry, one course, £6 6s; perpetual, £8 8s. Midwifery, one course, £3 3; perpetual, £6 6s. Botany, one course, £3 3s; perpetual, £4 4s Forensic Medicine, one course, £3 3s; perpetual, £4 4s. Dental Surgery, £2 2s.

London Hospital School.—Medicine, one course, £4 4s; perpetual, £7 7s. Surgery, one course, £3 3s; perpetual, £5 5s Materia Medica, one course, £4 4s; perpetual, £5 5s. Descriptive and Surgical Anatomy, one course, £6 6s; perpetual £10 10s. General Anatomy and Physiology, one course, £6 6s; perpetual, £10 10s. Chemistry, £7 7s. Toxicological Chemistry, £2 2s. Midwifery, one course, £4 4s; perpetual, £6 6s. Botany, one course, £3 3s; perpetual, £4 4s. Forensic Medicine, one course, £3 3s; perpetual, £4 4s.

St. Bartholomew's Hospital School.—Medicine, one course, £5 5s; perpetual, £7 7s. Surgery, one course, £5 5s; perpetual, £7 7s. Materia Medica, one course, £5 5s; perpetual, £7 7s. Descriptive and Surgical Anatomy, one course, £5 5s; perpetual, £10 10s. General Anatomy and Physiology, one course, £5 5s; perpetual, £10 10s. Comparative Anatomy, £1 1s. Chemistry, one course, £4 4s; perpetual, £8 8s. Practical Chemistry, £3 3s. Midwifery, one course, £4 4s; perpetual, £6 6s. Botany, one course, £3 3s; perpetual, £4 4s. Forensic Medicine, one course, £3 3s; perpetual, £4 4s.

Middlesex Hospital School.—Medicine, one course, £3 3s; perpetual £6 6s. Surgery, one course, £3 3s; perpetual, £5 5s. Materia Medica, one course, £3 3s; perpetual, £5 5s. Descriptive and Surgical Anatomy, one course, £3 3s; perpetual, £9 9s. General Anatomy and Physiology,

one course, £3 3s; perpetual, £9 9s. Chemistry, one course, £5 5s; perpetual, £6 6s. Midwifery, one course, £3 3s; perpetual, £5 5s. Botany, one course, £2 2s; perpetual, £3 3s. Forensic Medicine, one course, £3 3s; perpetual, £4 4s.

St. George's Hospital School.—Medicine, one course, £5 5s; perpetual, £6 6s. Surgery, one course, £4 4s; perpetual, £6 6s. Materia Medica, one course, £5 5s; perpetual, £6 6s. Descriptive and Surgical Anatomy, one course, £6 6s; perpetual, £8 8s. General Anatomy and Physiology, one course, £6 6s; perpetual, £8 8s. Chemistry, one course, £6 6s; perpetual, £8 8s. Midwifery, one course, £3 3s; perpetual, £5 5s. Botany, one course, £3 3s; perpetual, £4 4s. Forensic Medicine, one course, £3 3s; perpetual, £4 4s.

Westminster Hospital School.—Medicine, one course, £5 5s; perpetual, £6 6s. Surgery, one course, £4 4s; perpetual, £5 5s. Materia Medica, one course, £4 4s; perpetual, £5 5s. Descriptive and Surgical Anatomy, one course, £5 5s; perpetual, £7 7s. General Anatomy and Physiology, one course, £5 5s; perpetual, £7 7s. Chemistry, one course, £5 5s; perpetual, £6 6s. Midwifery, one course, £3 3s; perpetual, £5 5s. Botany, one course, £2 2s; perpetual, £3 3s. Forensic Medicine, one course, £2 2s; perpetual, £3 3s.

Charing-cross Hospital School.—Medicine, one course, £4 4s; perpetual, £7 7s. Surgery, one course, £3 3; perpetual, £6 6. Materia Medica, one course, £4 4s; perpetual, £6 6s. Descriptive and Surgical Anatomy, one course, £5 5s; perpetual, £8 8s. General Anatomy and Physiology, one course, £5 5s; perpetual, £8 8s. Chemistry, one course, £5 5s; perpetual, £7 7s. Midwifery, one course, £3 3s; perpetual, £6 6s. Botany, one course, £2 2s; perpetual, £4 4s. Forensic Medicine, one course, £2 2s; perpetual £4 4s. Pathological Anatomy, one course, £2 2s; perpetual, £4 4s

Aldersgate-street School.—Medicine, one course, £5 5s; perpetual, £6 6s. Surgery, one course, £3 3s; perpetual, £5 5s. Materia Medica, one course, £4 4s; perpetual, £5 5s. Descriptive and Surgical Anatomy, one course, £5 5s; perpetual, £7 7s. General Anatomy and Physiology, one course, £5 5; perpetual, £7 7s. Chemistry, one course, £5 5s; perpetual, £7 7s. Practical Chemistry, £2 2s. Midwifery, one course, £3 3s; perpetual, £5 5s. Botany, one course, £2 2s; perpetual, £3 3s. Forensic Medicine, one course, £2 2s; perpetual, £3 3s.

Grosvenor-place School. — Medicine, one course, £5 5s; perpetual, £6 6s. Surgery, one course, £3 3s; perpetual, £5 5s. Materia Medica, one course, £5 5s; perpetual, £6 6s. Descriptive and Surgical Anatomy, one course, £6 6s; perpetual, £8 8s. General Anatomy and Physiology, one course, £6 6s; perpetual, £8 8s. Chemistry and Practical Chemistry, one course, £5 5s; perpetual, £6 6s. Midwifery, one course, £3 3s; perpetual, £5 5s. Botany, one course, £2 2s; perpetual, £3 3s. Forensic Medicine, one course, £2 2s; perpetual, £3 3s.

Mr. Dermott's School.—Medicine, one course, £3 3s; perpetual, £5 5s. Surgery, one course, £3 3s; perpetual, £4. Materia Medica, one course, £3 3s; perpetual, £4. General and Surgical Anatomy, and Physiology, one course, £5 5s; perpetual, £7. Chemistry, one course, £4 4s; perpetual, £5. Midwifery, one course, £3 3s; perpetual, £5 5s. Botany, one course, £2 2s; perpetual, £3. Forensic Medicine, one course, £2 2s; perpetual, £3.

Royal Polytechnic Institution.—Lectures on Chemistry, £3 3s. Laboratory Practice, for any period, at the rate of £52 10 per annum.

Royal College of Chemistry.—Practical Chemistry. To students working daily for the session of five months, including the use of apparatus and materials, with some trifling exceptions, £12 10s; a corresponding reduction in the amount of the fee made to students working for a shorter time.

School of Pharmacy, Bloomsbury-square.—Materia Medica, £1 1s; to non-members of the Pharmaceutical Society, £2 2s. Chemistry, £1 1s; non-members, £2 2s. Organic Chemistry, 10s 6d; to non-members, £1 1s. Practical Pharmacy, 10s 6d; non-members, £1 1s.

LONDON HOSPITALS.

Guy's Hospital.—Medical Practice, eighteen months, £15 15s; perpetual, £24 4s. Surgical Practice, six months, £20; three years, £26 6s.

St. Thomas's. — Medical Practice, eighteen months, £15 15s; two years, or more, £24 3s. Surgical Practice, nine months, £20; perpetual, £26 6s.

St. Bartholomew's.—Medical Practice, nine months, £12 12s; eighteen months, £15 15s; perpetual, £31 10s. Surgical Practice, six months, £18 18s; twelve months, and more, £26 5s.

London.—Medical Practice, eighteen months, £10 10s; perpetual, £21. Surgical Practice, £21.

King's College. — Medical Practice, three months, £6 6s; six ditto, £10 10s; twelve or eighteen ditto, £15 15s; perpetual, £21. Surgical Practice, three months, £10 10s; six ditto, £15 15s; twelve or twenty-one, £21; perpetual, £26 5s.

University College.—Medical Practice, six months, £10 10s; twelve ditto, £15 15s. Surgical Practice, six months, £10 10s; twelve ditto, £15 15s; perpetual to both, £26 5s.

Middlesex.—Medical Practice, three months, £6 6s; six ditto, £10 10s; eighteen ditto, £15 15s; perpetual, £22 1s. Surgical Practice, three months, £10 10s; six ditto, £15 15s; three years, £21.

St. George's. — Medical Practice, eighteen months, £16 16s; perpetual, £25 4s. Surgical Practice, six months, £15 15s; one year, £21; perpetual, £52.

Westminster.—Medical Practice, six months, £10 10s; twelve ditto, £12 12s; eighteen ditto, £15 15s; perpetual, £21. Surgical Practice, six months, £12 12s; twelve ditto, £21; perpetual, £31.

Charing Cross.—Medical Practice, six months, £10 10s; perpetual, £15 15s. Surgical Practice, six months, £10 10s: perpetual, £15 15s.

Royal London Ophthalmic Hospital.—Three months, £5 5s; six months, £8 8s; perpetual, £10 10s.

Royal Westminster Ophthalmic Hospital.—Six months, £5 5s; perpetual, £10 10s.

Lock Hospital.—Six months, £6 6s; twelve ditto, £10 10s; perpetual, £31 10s.

General Lying-in Hospital, York Road.—Resident pupils, three months, £33 12s.

Orthopedic Institution.—Three months, £3 3s; perpetual, £5 5s.

Bethlem Hospital.—Six months, £15 15s; twelve ditto, £21.

Seaman's Hospital, Dreadnought.—Resident pupils, £8 per month; non-resident, three months, £5; perpetual, £10.

London Institution for Diseases of the Teeth.—Six months, £5 5s; perpetual, £10 10s.

Westminster General Dispensary.—Medical Practice, eighteen months, £5 5s.

Metropolitan Free Hospital.—Medical Practice, fifteen months, £6 6s.

ROYAL COLLEGE OF VETERINARY SURGEONS OF GREAT BRITAIN, 1844.

President, T. Turner, Esq., Croydon.

Vice-Presidents: Mr. Sewell, Mr. Cherry, Mr. Goodwin, sen., Mr. E. Turner, Mr. Spooner, Mr. J. Turner.

Treasurer, Mr. F. King.

Secretary, Mr. Gabriel.

Examiners—For England: Messrs. B. Cooper, R. Liston, E. Stanley, Professor Brande, Messrs. R. Field, E. Gabriel, J. Turner, W. Percival, G. Baker, H. J. Goodwin.

For Scotland:—Dr. Knox, Dr. Mercer, Dr. Mc Gregor, Dr. Lyon, Messrs. Williamson, Gray, sen., Tindall, Mather, Lyon, and the Veterinary Surgeon of the Regiment at Edinburgh.

Candidates are required to have served an apprenticeship of three years, to be twenty-one years of age, and to present certificates of having attended, during two sessional years, lectures delivered at the Royal Veterinary College of London, the Veterinary College of Edinburgh, or at some recognised school on the anatomy, physiology, and pathology of the horse, and other domesticated animals, on veterinary medicine and surgery, and on chemistry, materia medica, and pharmacy; also of having diligently dissected during the period of pupilage, and of being able to take off and put on a shoe, to drive the nails skilfully, pare out a foot, and search for its diseases. These certificates, which are required from candidates commencing their studies after the commencement of the present year, must be deposited with the secretary fourteen days before the examination takes place, the fee for which will be £5 5s.

Royal Veterinary College, Camden Town. President: H. R. H. the Duke of Cambridge. Professor of Pathology and Surgery: Mr. Sewell. Professor of Anatomy and Physiology: Mr. Spooner. Dissections and Demonstrations: Mr. Mayhew. Lecturer on Chemistry and Veterinary Materia Medica: Mr. W. J. T. Morton. Lecturer on Special Pathology and Surgery: Mr. J. B. Simonds. Hospital practice and clinical instruction daily, by Messrs. Sewell, Spooner, and Simonds. Perpetual fee for lectures and hospital practice, £21. The pupil must attend two sessional courses of lectures, and be twenty-one years of age, before he can be admitted for examination for the diploma, the fee for which is £5 5s.

MEDICAL AND SCIENTIC SOCIETIES OF LONDON.

Royal Society, Somerset-house. — Days of meeting, Thursday at half-past 8, p. m., from the third week in November to the third week in June, with the exception of Christmas, Passion, and Easter weeks. Anniversary, 30th of November. Fees, £4 annually; £10 admission; £60 composition.

Royal Institution, Albemarle-street. — Evening meetings on Friday, at 9, p.m., commencing the third week in January and continuing until the first week in June, with the exception of three weeks at Easter. Fees £5 5s annually; £6 6s admission; £63 composition.

Royal Medical and Chirurgical Society. 53, Berners-street.—Days of meeting, the second and fourth Tuesdays, at half-past 8, p.m., from November to June, Christmas and Easter weeks excepted. Anniversary the 1st of March. Fees £3 3s annually; £3 3s admission-fee; non-resident members composition, £6 6s without the transactions; £12 12s with.

Zoological Society, 11, Hanover-square.—Days of meeting, the second and fourth Tuesdays in the month, at half-past 8, p.m., and the first Thursday at 3, p.m., throughout the year. Anniversary the 29th of April. Fees, £3 annually; £5 admission-fee; £35 composition.

Linnæan Society, Soho-square.—Days of meeting, the first and third Tuesdays at 8, p.m., commencing in November and terminating in June, the first week in January and the third in May excepted. Anniversary, 24th of May. Fees, £3 annually; £6 admission-fee; £36 composition.

Royal Medico-Botanical Society, 32, Sackville-street.—Days of meeting, second and fourth Thursdays at 8, p.m., commencing in November and ending the second week in July, omitting Christmas, Passion, and Easter weeks, and the second week in January. Anniversary, 16th of January. Fees, £2 2s annually; £2 2 admission-fee; £21 composition; composition fee for country members £5 5s

Botanical Society, 20, Bedford-street, Covent-Garden.—Days of meeting, the first Friday in the month at 8, p.m., throughout the year. Anniversary, 29th of November. Fees, £1 1s annually; £7 7s composition for resident members: 10s 6d annually, £3 13s 6d composition, non-resident members. Admission-fee £1 1s.

Pharmaceutical Society, 17, Bloomsbury-square.—Days of meetings, second and fourth Wednesday at 9, p.m. throughout the year, except August and September. Anniversary, 21st of May. Fees, £1 11s 6d resident members; £1 1s non-resident members; 10s 6d associates.

Medical Society of London, Bolt-court, Fleet-street.—Days of meeting, Monday at 8, p.m., from the last week in September to the last week in May, except Christmas week. Anniversary, 8th of March. Fees, £1 1s annually; £1 1s admission-fee; £10 10s composition.

Hunterian Society, Bloomfield-street, Finsbury.—Days of meeting, alternate Wednesdays at 8, p.m. from October to June. Anniversary, 19th of February. Fees, £1 1s annually; £2 2s admission.

WESTMINSTER MEDICAL SOCIETY, 32, Sackville-street.—Days of meeting, Saturday at 8, p.m., from the third week in October to the last week in April, excepting Christmas and Easter weeks. Fees, 10s 6d annually; 10s 6d admission fee.

HARVEIAN SOCIETY, 17, Edward-street, Portman-square.—Days of meeting, the first and third Saturdays at 8, p.m., from October to May. Fees, £1 1s annually for three years.

CHEMICAL SOCIETY, Society of Arts, Adelphi.—Days of meeting, the first and third Monday at 8, p.m., from November to May. Anniversary, 31st of March. Fees, £2 annually for a resident member; £1 annually for one non-resident.

GEOLOGICAL SOCIETY, Somerset-house.—Days of meeting, alternate Wednesdays at half past 8, p.m., from November to June. Anniversary, 21st of February. Fees, £3 3s annual; £6 6s admission; £31 10s composition; £10 10s composition for non-resident members.

STATISTICAL SOCIETY, 11, Regent-street.—Days of meeting, the third Monday in the month, at 8, p.m., from November to June. Anniversary, 15th of March. Fees £2 2s annually; £21 composition.

ENTOMOLOGICAL SOCIETY, 17, Old Bond-street.—Days of meeting, the first Monday in the month, at 8, p.m., from November to June. Anniversary, 27th of January. Fees, £1 1s annually; £2 2s admission fee.

MICROSCOPICAL SOCIETY, 21, Regent-street.—Days of meeting, the second Wednesday in the month, at 8, p.m., from October to June. Anniversary, 19th of February.

ETHNOLOGICAL SOCIETY, 27, Sackville-street.—Days of meeting, the third Wednesday, 8, p.m., from November to June. Fee £2 2s annually.

ASTRONOMICAL SOCIETY, Somerset-house.—Days of meeting, the second Friday in the month, at 8, p.m., from November to June. Anniversary, 14th of February. Fees, £2 2s annually; £2 2s admission fee; £21 composition.

SCHOOLS OF MEDICINE IN THE PROVINCES.

QUEEN'S COLLEGE, BIRMINGHAM.—Medicine, one course, £4 4s; perpetual, £7 7s. Surgery, one course, £3 3s; perpetual, £5 5s. Materia Medica, one course, £4 4s; perpetual, £6 6s. Descriptive and Surgical Anatomy, one course, £3 3s; perpetual, £6 6s. General Anatomy and Physiology, one course, £5 5s; perpetual, £9 9s. Chemistry, one course, £4 4s; perpetual, £7 7s. Practical Chemistry, £2 2s. Midwifery, one course, £3 3s; perpetual, £6 6s. Botany, one course, £3 3s; perpetual, £4 4s. Forensic Medicine, one course, £3 3s; perpetual, £4 4s. College fee, £2 2s.

YORK.—Medicine, one course, £5 5s; perpetual, £8 8s. Surgery, one course, £3 3s; perpetual, £5 5s. Materia Medica, one course, £5 5s; perpetual, £7 7s. Descriptive and Surgical Anatomy, one course, £4 4s; perpetual, £7 7s. General Anatomy and Physiology, one course, £6 6s; perpetual, £10 10s. Chemistry, one course, £5 5s.; perpetual, £7 7s. Midwifery, one course, £3 3s.; perpetual, £5 5s. Botany, one course, £2 12s. 6d.; perpetual, £4 4s. Forensic Medicine, one course, £2 12s 6d; perpetual, £4 4s.

LIVERPOOL.—Medicine, one course, £5 5s. Surgery, one course, £4 4s. Materia Medica, one course, £5 5s. Descriptive and Surgical Anatomy, one course, £3 3s. General Anatomy and Physiology, one course, £5 5s. Chemistry, one course, £5 5s. Midwifery, one course, £3 3s. Botany, one course, £3 3s. Forensic Medicine, one course, £3 3s.

LEEDS.—Medicine, first course, £5 5s; second ditto, £3 3s. Surgery, first course, £3 3s; second ditto, £2 2s. Materia Medica, first course, £5 5s; second ditto, £3 3s. Descriptive and Surgical Anatomy, first course, £4 4s; second ditto, £3 3s. General Anatomy and Physiology, first course, £6 6s; second ditto, £4 4s. Chemistry, first course, £4 4s; second ditto, £3 3s. Midwifery, first course, £3 3s; second ditto, £2 2s. Botany, first course, £2 12s 6d; second ditto, £1 11s 6d. Forensic Medicine, first course, £2 12s 6d; second ditto, £1 11s 6d.

NEWCASTLE-UPON-TYNE.—Medicine, one course, £3 3s. Surgery, one course, £3 3s. Materia Medica, one course, £3 3s. Descriptive and Surgical Anatomy, one course, £3 3s. General Anatomy and Physiology, one course, £4 4s. Chemistry, one course, £3 3s. Practical Chemistry, £3 3s. Midwifery, one course, £3 3s. Botany, one course, £3 3s. Forensic Medicine, one course, £3 3s. Operative Surgery, one course (summer), £1 11s 6d.

MANCHESTER.—Medicine, one course, £4 4s. Surgery, one course, £4 4s. Materia Medica, one course, £4 4s. Descriptive and Surgical Anatomy, one course, £2 2s. General Anatomy and Physiology, one course, £4 4s. Ophthalmic Surgery, one course, £1 1s. Chemistry, one course, £4 4s. General Pathology and Morbid Anatomy, one course, £1 1s. Midwifery, one course, £4 4s. Botany, one course, £3 3s. Forensic Medicine, one course, £3 3s.

HULL AND EAST RIDING.—Medicine, one course, £5 5s; perpetual, £7 7s. Surgery, one course, £3 3s; perpetual, £5 5s. Materia Medica, one course, £5 5s; perpetual, £7 7s. Descriptive and Surgical Anatomy, one course, £4 4s; perpetual, £6 6s. General Anatomy and Physiology, one course, £5 5s; perpetual, £8 8s. Chemistry, £5 5s. Midwifery, one course, £4 4s; perpetual, £6 6s. Botany, £3 3s. Forensic Medicine, £3 3s.

SHEFFIELD.—Medicine, first course, £5 5s; second ditto, £3 3s. Surgery, one course, £3 3s. Materia Medica, first course, £5 5s; second ditto, £3 3s. Descriptive and Surgical Anatomy, first course, £4 4s; second ditto, £3 3s. General Anatomy and Physiology, first course, £6 6s; second ditto, £4 4s. Chemistry, first course, £5 5s; second ditto, £3 3s. Midwifery, one course, £3 3s. Botany, £2 12s 6d. Forensic Medicine, £2 12s 6d.

BRISTOL.—Medicine, one course, £4 4s; perpetual, £6 6s. Surgery, one course, £4 4s; perpetual, £6 6s. Materia Medica, one course, £4 4s; perpetual, £6 6s. Descriptive and Surgical Anatomy, one course, £5 5s; perpetual, £9 9s. General Anatomy and Physiology, one course, £5 5s; perpetual, £9 9s. Chemistry, one course, £5 5s; perpetual, £8 8s. Practical Chemistry, £3 3s. Midwifery, one course, £4 4s; perpetual, £6 6s. Botany, one course, £3 3s; perpetual, £5 5s. Forensic Medicine, one course, £3 3s; perpetual, £5 5s.

PROVINCIAL RECOGNISED HOSPITALS.

BATH UNITED HOSPITAL—(100 beds)—Dresser's or pupil's fee, £26 5s.

GENERAL HOSPITAL, BIRMINGHAM.—Medical practice, eighteen months, £12. Surgical practice, three years, £50.

QUEEN'S HOSPITAL, BIRMINGHAM.—Medical practice, six months, £5 5s; twelve ditto, £10 10s; perpetual, £12 12s. Surgical practice, six months, £10 10s; twelve ditto, £16 16s; perpetual, £21 5s.

BRISTOL INFIRMARY.—Medical practice, twelve months, £15. Surgical practice, twelve months, £25. Dresser for the same period, £52 10s.

ST. PETER'S HOSPITAL.—Medical practice, twelve months, £20.

ADDENBROOKE'S HOSPITAL, CAMBRIDGE.—Medical and Surgical practice, six months, £8 8s; twelve ditto, £10 10s; perpetual, £15 15s.

KENT AND CANTERBURY HOSPITAL.—Medical and Surgical attendance gratuitous.

DERBYSHIRE GENERAL INFIRMARY.—Medical and Surgical practice, £5 5s annually.

DEVON AND EXETER HOSPITAL.—Medical practice, twelve months, £31 10s.

GLOUCESTER INFIRMARY.—Medical practice, twelve months, £10 10s. Surgical practice. Dressers and apprentices pay from £30 to £40 a-year.

HULL GENERAL INFIRMARY.—Medical and Surgical practice, perpetual, £23 2s.

LEEDS INFIRMARY.—Medical practice, six months, £9 9s; twelve ditto, £12 12s; eighteen ditto, £15 15s; perpetual, £21. Surgical practice, twelve months, £12 12s; two years, £15 15s; perpetual, £21.

LIVERPOOL INFIRMARY.—Medical and Surgical practice, eighteen months, £26 5s; three years, £42. Dresser, £21; for three years, £42.

LIVERPOOL NORTHERN HOSPITAL.—Medical and Surgical practice, twelve months, £10 10s; three years, £31 10s.

MANCHESTER ROYAL INFIRMARY.—Medical Practice, three years, £15 15s. Surgical Practice, pupil, three years, £21; Dresser, three years, £31 10s.

NEWCASTLE INFIRMARY.—Medical and Surgical Practice, six months, £3 3s; twelve ditto, £5 5s.

NORTHAMPTON INFIRMARY.—Medical and Surgical Practice, £30 a-year.

SALOP INFIRMARY.—Medical and Surgical Practice, £21 per annum.

SHEFFIELD INFIRMARY.—Medical Practice, one year, £10 10s; two years, £15 15s. Surgical Practice, one year, £10 10s; two ditto, £15 15s; three ditto, £21. Dressership, one year, £10 10s additional.

STAFFORDSHIRE GENERAL INFIRMARY.—Medical and Surgical Practice, £5 5s annually.

WORCESTER INFIRMARY.—Pupil's fees, £31 10s for twelve months.

YORK COUNTY HOSPITAL.—Medical Practice, eighteen months, £12 12s; perpetual, £15 15s. Surgical Practice, twelve months, £12 12s; perpetual, £15 15s; perpetual to both, £26 5s.

Regulations of the Army Medical Department.

13, ST. JAMES' PLACE.

A candidate for an assistant-surgeoncy in the army is required to fill up a blank form of certificate, which may be obtained at the office by written application to the director-general. The candidate is, in addition, to sign and forward the following declaration:—

"I [Christian name and surname at full length], years of age, a candidate for employment in the medical department of the army, do hereby attest my readiness to engage for general service, whether at home or abroad, and to proceed on duty immediately on being gazetted. I declare my age not to exceed twenty-six years, that I am unmarried, and that I labour under no mental or constitutional disease, nor physical disability, that can interfere with the most efficient discharge of the duties of a medical officer in any climate." [Signature.] ......

In selecting from among the candidates for the medical department of the army, a preference is given to those who can fill up all the blanks in the printed form; but the name of no gentleman can be placed on the list who does not possess the diploma of either of the colleges of surgeons of London, Edinburgh, or Dublin, and who cannot produce the following testimonials:—Eighteen months' attendance at a hospital of celebrity, where the average number of in-patients is not less than 100; twenty-four months' anatomy; twelve months' practical anatomy; twelve months' surgery, or (what is preferred) six months' surgery, and six months' military surgery; eight months' clinical surgery, a complete course of two or three lectures during the week; twelve months' practice of physic, or six months' of practice of physic, and six months' of general pathology; eight months' clinical lectures on ditto, the same as required in surgery; twelve months' chemistry; six months' practical chemistry; three months' botany; four months' materia medica; three months' practical pharmacy, or apprenticeship; five months' natural history; five months' midwifery; five months' natural philosophy.

The candidates must be unmarried, not beyond twenty-six years of age, nor under twenty-one years.

Candidates who have had an university education, and have the degree of A.B. or A.M., as well as that of M.D., will be preferred, but a liberal education, and a competent knowledge of the Greek and Latin languages are indispensably requisite in every candidate, and the greater the attainments of the candidates in various branches of science, in addition to competent professional knowledge, the more eligible will they subsequently be deemed for promotion in the service; for selections to fill up vacancies will be guided more by reference to such acquirements than to mere seniority. Before promotion from the rank of assistant-surgeon to any higher rank, every gentleman must be prepared for such other examination as may be ordered before a board of medical officers.

All communications to be forwarded "unsealed," under cover, to "the Right Honourable the Secretary at War," with the words "Army Medical Department" at the corner.

Although, in the examination of candidates, gentlemen are expected to be qualified in every branch of study required, they are requested to be particularly conversant in the knowledge of: 1. Tropical diseases, and the diseases to which soldiers are the most liable; 2. Military surgery, and works on the habits of soldiers and the rules of the service; 3. Cullen's Nosology, being that adopted in all returns and reports; 4. Willan's Classification of Cutaneous Diseases; 5. The latest authors on the diseases of the eye. They are expected readily to translate a passage from a Greek or Latin author; to be conversant with Baillie and the later authors on morbid anatomy; with Cullen's, Mason Good's, and Gregory's Practice of Physic, the latter giving an account of tropical diseases, and those most commonly met with in the army; with the works of Hunter, Hennen, Dr. John Thompson, Guthrie, Samuel Cooper, Millingen, Ballingall, Marshall, and Baron Larrey, on Military Surgery; with the works of Chisholm, Bancroft, Lind, Blane, Burnet, Johnstone, and Annesley, on the diseases of warm climates; but Baillie's Morbid Anatomy, Hennen's and Ballingall's Military Surgery, 3rd edition, with his valuable work on Medical Topography, Guthrie on gun-shot wounds and on the eye, and Gregory's Practice of Physic, should form part of the baggage of every military surgeon.

Candidates, after passing their examination, will not have any leave of absence granted, but will be stationed at Chatham for two or three months previously to being gazetted, and on their conduct there will depend their obtaining their commissions. The appointment of army assistant-surgeons rests with the director-general, Sir James M'Grigor, Bart., by whom the examinations are generally conducted.

NAVAL MEDICAL DEPARTMENT,

ADMIRALTY OFFICE, SOMERSET HOUSE.

Director-General of the Medical Department of the Navy, Sir William Burnett, M.D., Knt, K.C.H., F.R.S.

Candidates must possess a diploma, or a certificate of qualification, from one of the Colleges of Surgeons, and in every case will also undergo a further examination before the director-general touching his qualifications in all the necessary branches and points of medicine and surgery for each of the steps in the naval medical service; and further, previously to the admission of assistant-surgeons into the navy, it will be required that they produce proof of having received a preliminary classical education, and that they possess, in particular, a competent knowledge of Latin; also, that they are of good moral character, the certificate of which must be signed by the clergyman of the parish, or by a magistrate of the district. That they have served an apprenticeship, or have been engaged for not less than six months in practical pharmacy. That their age be not less than twenty years, nor more than twenty-four, and that they are unmarried. That they have actually attended a hospital in London, Edinburgh, Dublin, Glasgow, or Aberdeen, for two years, subsequently to the age of eighteen, in which the average number of patients is not less than 150. That they have been engaged in actual dissections of the human body twelve months; the certificate of which, from the teacher, must state the number of subjects or parts dissected by the candidate. That they have attended lectures, &c., on the following subjects, at established schools of eminence, by physicians or surgeons of the recognised colleges of physicians and surgeons in the United Kingdom, for periods not less than hereunder stated, observing, however, that such lectures will not be admitted if the teacher shall lecture on more than one branch of science, or if the lectures on anatomy, surgery, and medicine, be not attended during three distinct winter sessions of six months each.

Anatomy (or general anatomy twelve months, and comparative anatomy six months), eighteen months. Surgery (or general surgery twelve months, and military surgery six months), eighteen months. Theory of medicine, six months. Practice of ditto, twelve months. If the lectures on the theory and practice of medicine are given in conjunction, then the period required is eighteen months (six months' lectures on pathology, if given at a university where there may be a professorship of that branch of science, will be admitted in lieu of six months' lectures on the practice of medicine). Clinical lectures, at a hospital as above (or the practice of medicine six months, and the practice of surgery six months), twelve months. Chemistry (or lectures on chemistry three months, and practical chemistry three months), six months. Materia Medica, six months. Midwifery (accompanied by certificates stating the number of midwifery cases personally attended), six months. Botany (or general botany three months, and medical botany three months), six months.

Although the above are the only qualifications which are absolutely required in candidates for the appointment of assistant-surgeon, a favourable consideration will be given to the cases of those who have obtained the degree of M.D. at either of the universities of Oxford, Cambridge, Edinburgh, Dublin, Glasgow, or London, or who, by possessing a knowledge of diseases of the eye, and of any branch of science connected with the profession, such as medical jurisprudence, natural history, natural philosophy, &c., appear to be more peculiarly eligible for admission into the service, observing, however, that lectures on these or any other subjects cannot be admitted as compensating for any deficiency in those required by the regulations.

By the rules of the service, no assistant-surgeon can be promoted to the rank of surgeon until he shall have served three years in the former capacity, one year of which must be in a ship actually employed at sea; and it is resolved, that not any diploma or certificate of examination from either of the aforesaid royal colleges shall be admitted toward the qualification for surgeon, unless the diploma or certificate shall be obtained on an examination passed after a period of not less than three years' actual service, observing that no one can be admitted to an examination for surgeon unless he be a member of one of the above-named royal colleges, and whenever assistant-surgeons, already in the service (whose professional education may not be in accordance with the above), obtain leave to study previously to their passing for surgeon, they will be required, on their examination, to produce testimonials of their having availed themselves of the period of leave to complete their education agreeably to these regulations.

It is also to be observed, that candidates who may be admitted into the naval medical service must serve in whatever ships, &c., they may be appointed to, and that, in the event of their being unable to do so from sea-sickness, their names cannot be continued on the naval medical list, nor can they, of course, be allowed half-pay.

ORDNANCE MEDICAL DEPARTMENT.

WOOLWICH.

Director-General, Sir John Webb, K.C.H.

Regulations for the Admission of Candidates.—Provisional List.—Medical students who have completed their twentieth year, who have been well instructed in the Latin and Greek languages, the elements of mathematics and natural philosophy, and who can produce satisfactory proofs of being of good moral character, and diligent in the study of their profession and the sciences connected with it, may be entered in the provisional list of gentlemen desirous to be admitted candidates for employment in the Ordnance Medical Department. A knowledge also of modern languages, though not indispensable at the time of provisional reception, is highly desirable, and will be duly appreciated.

The candidate must be twenty-two years of age, and under twenty-five. He must also be unmarried, and in the full enjoyment of health, both bodily and mental.

Qualifications.—Every candidate must produce a diploma from one of the colleges of surgeons of London, Edinburgh, or Dublin; and a certificate of qualification from the society of apothecaries in London. He must also bring proof of having diligently gone through the following branches of professional education, viz:—Of having served an apprenticeship of five years to a surgeon and apothecary, if educated in England; but if not, qualification in the practice of medicine and pharmacy equivalent thereto; of having attended the practice of surgery in a recognised hospital or hospitals, where clinical instruction is constantly given, for three years, three months being allowed for a vacation in each year; of having attended the under-mentioned lectures, &c.:—Three sessions of anatomical lectures, demonstrations, and dissections; one course of morbid anatomy and pathology; two of lectures on surgery, or one course of surgery and one of military surgery; one of natural history or comparative anatomy; one of chemistry; one of botany; one of materia medica and therapeutics; two of eighteen months' medical practice, with clinical lectures, commencing the second session—viz., twelve months in a recognised hospital, and the remaining six months either in a recognised hospital or a dispensary; one course of medical jurisprudence, with toxicology; two of midwifery; not less than thirty cases of practical midwifery; and one course on diseases of the eye.

He must produce a diploma from either of the colleges of London, Edinburgh, or Dublin; and if not a graduated M.D. of Scotland or Ireland, after having actually passed an examination in the university where he has obtained his degree; a certificate of qualification also from the Society of Apothecaries in London. It is likewise expected that candidates shall have attended establishments for the cure of diseases of the ear and skin; and for the treatment of patients affected with mental derangement. The moral conduct and character of each individual must be certified by the gentleman to whose care his education was confided; and also by a clergyman who, if practicable, should be the incumbent or officiating minister of the parish in which the applicant usually resides. The full qualification being required on admission, a second examination is deemed unnecessary.

EAST INDIA COMPANY'S SERVICE.

Examiner in Medicine, Dr. Scott, of Barnes.

Candidates must be twenty-two years of age, and in possession of a surgical diploma, or else undergo an examination before the College of Surgeons. They are also required to produce a certificate from the cupper of a public hospital in London, of having acquired the art of cupping, and being capable of practising it with proper dexterity.

Qualification in Physic.—The candidate will also be required to pass an examination by Dr. Scott in the practice of physic, in which examination will be included as much anatomy and physiology as is necessary for understanding the causes and treatment of internal diseases, as well as the art of prescribing and compounding medicines; and Dr. Scott will require him to produce satisfactory proof of having attended at least two courses of lectures on the practice of physic; and, above all, that he should produce a certificate of having attended diligently the practice of the physicians at a general hospital in London for six months, or at a general hospital in the country (within the United Kingdom) for six months, provided such provincial hospital contains at least, on an average, one hundred in-patients, and has attached to it a regular establishment of physicians as well as surgeons. No attendance on the practice of a physician at any dispensary will be admitted. Candidates are desired to present themselves to Mr. T. R. Clarke, clerk for passing cadets and assistant-surgeons, at the East India House, with their certificates, as underneath, properly filled up and signed, by ten o'clock in the morning, or as soon after as possible, in order that they may have their nominations prepared against the committee meet, or the nominating director arrives; in failure of which they may have to wait for several hours, or to come another day.

Should it be discovered at the time the assistant-surgeon is appointed, or at any subsequent period, that his appointment has been obtained by purchase or agreement to pay any pecuniary or valuable consideration whatsoever, either directly or indirectly, when the appointment is completed, he will not only be dismissed, and rendered ineligible to hold any situation in the East Company's service, under the court's resolution of the 9th August, 1809, but all the parties concerned in procuring the appointment surreptitiously, or in disposing of, or receiving the same under such circumstances, will subject themselves individually and collectively to a criminal

prosecution for a misdemeanour, under the Act of the 49th of George the Third, cap. 126; and the Court of Directors of the East India Company do hereby declare that they will prosecute any person or persons who shall hereafter be detected in such illicit traffic. If an assistant-surgeon produces a false certificate, or the dates are found to have been altered for the purpose of making him appear to be of a proper age, he is rendered ineligible to hold any situation in the company's service.

SCOTLAND.

UNIVERSITY OF EDINBURGH, 1582.

Principal, Rev. John Lee, D.D.
Secretary to the Senate, Sir W. Hamilton, Bart.
Court of Examiners in Medicine: Dr. Monro, Sir G. Ballingall, Drs. Thompson, Graham, Alison, Christison, Simpson, Traill, Henderson, Gregory, Messrs. Miller, Syme, Jameson.
Professors: Dietetics, Materia Medica, and Pharmacy, Dr. Christison. Medical Jurisprudence and Police, Dr. Traill. Chemistry, Dr. Gregory. Surgery, Mr. Miller. Practice of Physic, Dr. Alison. Anatomy and Physiology, Dr. Monro. Military Surgery, Sir G. Ballingall. General Pathology, Dr. Henderson. Natural History, Mr. Jameson. Institutes of Medicine, or Physiology, Dr. A. Thomson. Midwifery and Diseases of Women and Children, Dr. Simpson. Clinical Medicine, Drs. Alison, ———, Traill, and Christison. Clinical Surgery, Mr. Syme. Botany, Dr. ———. Royal Infirmary, noon, daily. Practical Anatomy, (under the superintendence of Dr. Monro.) Practical Chemistry and Pharmacy.
Fee for each course, £4 4s.

Statutes relative to the Degree of M.D.

Candidates for the degree of M.D. must have studied anatomy, chemistry, materia medica and pharmacy, institutes of medicine, practice of medicine, surgery, midwifery and diseases peculiar to women and children, general pathology, practical anatomy, during courses of six months. Clinical medicine, that is, the treatment of patients in a public hospital, under a professor of medicine, by whom lectures on the cases are given, during courses of six months, or two courses of three months. Clinical surgery, medical jurisprudence, botany, natural history, including zoology, during courses of at least three months. Besides the course of clinical medicine already prescribed, he must attend for at least six months, the medical or surgical practice of a general hospital, either at Edinburgh or elsewhere, containing not fewer than eighty patients. And he must also have attended to practical pharmacy, for at least six months. The candidate for the degree of doctor must also have studied in the manner already prescribed, for at least one year previously to his graduation, in the University of Edinburgh.

Every candidate must deliver, before the 24th of March of the year in which he proposes to graduate, to the dean of the faculty of medicine.—1. A declaration, in his own hand-writing, that he is twenty-one years of age, or will be so before the day of graduation, and that he will not be then under articles of apprenticeship to any surgeon or other master. 2. A statement of his studies, as well in literature and philosophy as in medicine, accompanied with proper certificates. 3. A medical dissertation, composed by himself in Latin or in English, to be perused by a professor, and subject to his approval. He will be examined first as to his proficiency in Latin, and afterwards on anatomy, chemistry, botany, institutes of medicine, and natural history bearing chiefly on zoology; and on materia medica, pathology, practice of medicine, surgery, midwifery, and medical jurisprudence. He may also be called upon to defend hitherto. The calling day is the first lawful day in August. Fee for graduation £25.

UNIVERSITY OF GLASGOW, 1450.

Chancellor, Duke of Montrose.
Vice-Chancellor, The Principal.
Rector, Mr. Rutherford, M.P.
Principal, Duncan M'Farlan, D.D.
Secretary, W. Meiklelham, jun., L.L.D.
Professors: Materia Medica, John Couper, M.D. Chemistry, Thomas Thomson, M.D. Demonstrations, Dr. Jeffray and Dr. Marshall. Surgery, John Burns, M.D. Practice of Physic, William Thompson, M.D. Midwifery, John M. Pagan, M.D. Anatomy, James Jeffray, M.D. Practical Chemistry, Dr. R. D. Thomson. Botany, John Hutton Balfour, M.D. Institutes of Medicine, A. Buchanan, M.D. Forensic Medicine, Harry Rainy, M.D. Natural History, William Couper, M.D. Waltonian Lecturer, Eye, William Mackenzie, M.D.
Examiners appointed: Professors J. Jeffray, W. Thomson, John Burns, T. Thomson, J. Cooper, A. Buchanan, J. H. Balfour, J.M. Pagan, and H. Rainy.
Fees, £3 3s each course.

Candidates for the degree in medicine must be twenty-one years of age, and produce a certificate of moral character, and evidence of four years' medical study, one of which must be passed at this university.

Certificates are required of having attended one or more courses of lectures on the following subjects, each course, except forensic medicine and botany, being of six months' duration; if of less extent, then two courses will be deemed equivalent to one of six months:—Anatomy and physiology; chemistry; the theory or institutes of medicine; practice of medicine; materia medica and pharmacy; midwifery; surgery; forensic medicine; botany (no course of botany attended previously to 1839-40 is received, unless delivered in a university); anatomical dissections; and two years' practice of a general hospital, containing eighty beds, and in which the student must spend at least one-half of the period of attendance in the physicians' wards. Neither hospital attendance nor anatomical dissections shall be considered as equivalent to a course of lectures. A schedule of the course of study, with an English essay on some medical subject must be delivered to the clerk of the senate two months before the time of graduation, that is, on or before the 1st of March or 10th of June. The examination will comprise Latin, and all the subjects included in the curriculum.

Candidates for the degree in surgery, besides the certificate of age and moral character, must produce evidence that they have attended medical lectures in one or other of the universities or schools already specified for four years, during which they must have attended one or more courses on the following subjects, the extent of each course, with the exception of forensic medicine, being six months, or the equivalent two courses of a shorter duration. The candidate must have attended not less than three courses of medical lectures in the University of Glasgow. In each year of his study he must attend at least two or more courses of lectures, of six months' duration, on anatomy, surgery, chemistry, theory or institutes of medicine, practice of medicine, midwifery, materia medica and pharmacy, forensic medicine, anatomical dissections, and two years' practice of a general hospital, in which the student must attend one-half of the prescribed period in the surgical wards, and the other half in the medical.

UNIVERSITY AND KING'S COLLEGE, ABERDEEN, 1494.

Chancellor, Earl of Aberdeen, K.T.
Principal, William Jack, D.D.
Sub-Principal, H. Macpherson, M.D.
Librarian, G. Dickie, M.D.
Secretary, A. Fyfe, M.D.
Professors: Mathematics, John Tullock, A.M. Moral Philosophy, H. Scott, A.M. Natural Philosophy, J. Fleming, D.D. Medicine and Chemistry, A. Fyfe, M.D.
University Lecturers: Materia Medica, W. Templeton, M.D. Anatomy and Physiology, Edward B. Shirreff, Esq. Practice of Medicine, A. Kilgour, M.D. Surgery, David Kerr, M.D. Midwifery, A. Fraser, Esq. Institutes of Medicine, W. Mitchell, Esq. Medical Jurisprudence, W. C. Fowler, Esq. Botany, G. Dickie, M.D.
Fees for each course, £3 3s.

Regulations to be observed in granting Degrees of Medicine.

All candidates for the degree of M.D. must be of the age of twenty-one years, and must produce satisfactory certificates of moral character, and exhibit the diploma of A.M. from some university.

All candidates, with the exceptions mentioned below, must have been engaged in the study of medicine for at least four years, one of which must be passed in Aberdeen, and must produce evidence of having attended, in some recognised school of medicine, the following courses of lectures:—Six months' courses—anatomy, two courses; chemistry, one course; materia medica, one course; surgery, one course; institutes of medicine and physiology, one course; practice of medicine, one course; midwifery, one course. Three months' courses—dissections, two courses; practical chemistry, one course; medical jurisprudence, one course; clinical surgery, one course; botany, one course; clinical medicine, two courses. He must also have attended for two years the wards of a hospital containing 100 beds; and during three months, a shop or dispensary for the compounding of medicines. The preceding regulations are strictly enforced in the case of all students who have commenced their medical studies at a period subsequent to 1st October, 1840, but gentlemen who possess a licence or diploma from any of the royal colleges of physicians or surgeons, and who have been engaged for at least five years in the practice of medicine, are admitted to examination, on producing their licence or diploma, along with satisfactory evidence of sufficient preliminary education and of good moral character. In the case of students who have commenced their medical education previously to the above period, and who have not the degree of A.M., the senatus reserves the power of judging of their preliminary education by examination, or otherwise. Diploma fee, £26 5s 6d.

Degrees in medicine are conferred at two stated periods annually—viz., at the end of April, and at the end of July.

MARISCHAL COLLEGE AND UNIVERSITY, ABERDEEN. (1593.)

Chancellor, Duke of Richmond.
Principal, Daniel Dewar, LL.D. and D.D.
Secretary, John Cruickshank, LL.D.
Professors: Natural History, W. M'Gillivray, LL.D. Mathematics, John Cruickshank, LL.D. Natural Philosophy, William Knight, LL.D. Moral Philosophy and Logic, George Glenny, D.D. Chemistry, Thomas Clarke, M.D. Anatomy, Alex. J. Lizars, M.D. Surgery, William Pirrie, M.D. Practice of Medicine, John Macrobin, M.D.
Lecturers: Botany, William M'Gillivray, LL.D. Materia Medica, William Henderson, M.D. Institutes of Medicine, Alex. Harvey, M.D. Midwifery, Robert Dyce, M.D. Medical Jurisprudence, Francis Ogston, M.D. Chemistry, Dr. Clark and Mr. Shier, £2 2s. Practical Chemistry, Dr. Clark and Mr. Shier, £3 3s. Anatomy, elementary course, Dr. Lizars, £3 3s. Anatomy, advanced course, Dr. Lizars, £3 3s. Materia medica, Pharmacy, and Dietetics, Dr. Henderson, £3 3s. Institutes of Medicine, Dr. Harvey, £3 3s. Principles, Practice, and Operations of Surgery, Dr. Pirrie, £3 3s. Principles and Practice of Medicine, Dr. Macrobin, £3 3s. Midwifery and Diseases of Women and Children, Dr. Dyce, £3 3s. Medical Jurisprudence, Dr. Ogston, £2 2s. Botany, Dr. McGillivray, £1 11s 6d.

Students are entitled to attend both courses of anatomy, with dissections, for one fee of three guineas.

Regulations for granting Medical Degrees.

Curriculum.—Four years of attendance on medical classes, of which one year may be passed at any recognised medical school; but three, at least, must be passed in a university, including one, at least, in this university. The attendance, in each year, to embrace not fewer than two medical classes of six months each; or one of six months, with two of three months each. The university attendance to include the following eight classes, each for a course of six months:—Anatomy, practical anatomy, che-

mistry, materia medica, institutes of medicine, surgery, practice of medicine, midwifery, and the following three classes, each for a course of three months—botany, practical chemistry, medical jurisprudence. Eighteen months' attendance on the medical and surgical practice of a hospital containing not fewer that eighty beds, along with attendance for six months on lectures on clinical medicine, and for three months on lectures on clinical surgery. Six months of compounding and dispensing medicines in the laboratory of a hospital, or of a public dispensary, or of a licensed general practitioner, or of a regular dispensing druggist. Qualified medical practitioners are admitted to examination, on presenting their diploma, after one winter's attendance on the university classes.

Examinations.—The examination terms are two in each year—the *first* to commence on the 20th of April, if a Wednesday, but if not, on the first Wednesday thereafter; the *second* on the 13th of October, if a Wednesday, but if not, on the first Wednesday thereafter. Every candidate to undergo at least three separate professional examinations —the first, pharmaceutical; the second, surgical; the third, medical; to be conducted partly in writing, as well as *viva voce*, and partly by demonstration. The *first* to include chemistry, botany, materia medica, pharmacy, and the doctrines of physics relating to specific gravities, to gases and vapours, and to climate. The *second* to include anatomy, institutes of medicine, surgery, and the doctrines of chemistry and physics illustrative of animal structure and function. The *third* to include the practice of medicine, midwifery, and medical jurisprudence. Candidates not M.A. are also examined in the fourth book of Celsus.

Fees.—For the degree of bachelor of medicine, expense of diploma, £1; for the degree of doctor of medicine, expense of diploma, £1; government stamp, £10—£11. There are not any examiners' fees.

UNIVERSITY OF ST. ANDREWS, 1412.

Chancellor, Lord Melville.

Principal of the United College of St. Salvador and St. Leonard, Sir David Brewster, LL.D., F.R.SS.L. and E.

Professors: Natural Philosophy, Adam Adamson, LL.D., F.R.S.E. Moral Philosophy and Political Economy, George Cook, D.D., F.R.S.E. Mathematics, Thomas Duncan, A.M. Anatomy and Medicine, John Reid, M.D. Chemistry, Arthur Connel, F.R.S.E. Fees £3 3s each class.

Principal of St. Mary's, or New College, Robert Haldane, D.D. Secretary, James Hunter, LL.D.

Board of Examiners for Degrees in Medicine: Dr. W. Pyper, Professor of Humanity; John Reid, M.D., Professor of Anatomy and Medicine; Arthur Connel, F.R.S.E., Professor of Chemistry; David Skae, F.R.C.S.E., Lecturer on Forensic Medicine; J. Argyll Robertson, M.D., F.R.S.E., Lecturer on Surgery, Edinburgh; Alexander J. Hannay, M.D., F.F.P. and S., and Professor of the Practice of Physic, Andersonian University, Glasgow.

Regulations for granting Medical Degrees.

The candidate must produce evidence of unexceptionable moral character, and that he is twenty-one years of age. He must produce certificates that he has regularly attended lectures for at least four complete winter sessions, or three winter and three summer sessions, on the following branches:—1. anatomy, two courses of six months each; 2. practical anatomy, twelve months; 3. theory of medicine, or physiology, one course of six months; 4. chemistry, one course of six months; 5. practical chemistry, one course of three months; 6. materia medicine and pharmacy, one course of six months; 7. surgery, one course of six months; 8. clinical medicine, one course of six months; 9. practice of medicine, one course of six months; 10. clinical surgery, one course of six months; 11. midwifery, and diseases of women and children, one course of three months; 12. an apprenticeship, or six months' attendance in the shop of an apothecary, or in the laboratory of a public hospital or dispensary; 13. attendance at a public hospital, containing not less than eighty beds, for at least eighteen months. These regulations will be invariably observed, except when the candidate is possessed of a surgeon's diploma or license from the colleges of London, Edinburgh, or Dublin, or the Faculty of Physicians and Surgeons of Glasgow, or a license from the Apothecaries' Company, in which case he has merely to present such diploma or license previous to examination for M.D.

Diploma fees £25 3s.

ROYAL COLLEGE OF PHYSICIANS. EDINBURGH.

President, Dr. Beilby.

Vice-president, Dr. Renton.

Treasurer, Dr. Ransford.

Censors, Drs. Davidson and Wood.

Secretary, Dr. Craigie.

Librarian, Dr. Seller.

Examiners of Foreign Graduates: Drs. Beilby, Renton, Davidson, Christison, Craigie, Ransford, and Paterson.

The members of the college are respectively entitled ordinary fellows, non-resident ordinary fellows, and licentiates. Foreign graduates only undergo an examination, and that may be avoided, even in this case, by a ballot among the fellows. If an examination take place, it will consist of three trials; the first by two fellows appointed by the college, on any part of medicine; the second by two others, on two aphorisms of Hippocrates; and the third by two others, on two medical cases. All these trials are in presence of the college, and in the Latin language.

Fees.—The fee to be paid by a resident licentiate is £100; by a non-resident £55, exclusive of any tax payable to government now existing, or which may hereafter be imposed, and must be lodged with the treasurer previously to presenting the petitions. Every resident fellow pays an annual subscription of £1 1s to defray the college expenses.

ROYAL COLLEGE OF SURGEONS, EDINBURGH, 1505.

President, Dr. James Simson.

Treasurer, Dr. Alexander Macaulay.

Librarian, Dr. Robert Ormond.

Secretary, John Scott, W.S.

Examinators: Drs. John Gairdner, William Brown, John M'Farlan, James Pitcairn, Richard Huie, John Campbell, Archibald Inglis, William Dumbreck, Andrew Wood, Francis Farquharson, John Scott, Robert Ormond.

Assessors to Examinators: W. Wood, Drs. Adam Hunter, David Maclagan, Sir G. Ballingall.

Regulations for Fellows.—The candidate is required to present an essay on some surgical subject, which, if approved of, he must print for circulation among the fellows. He must then undergo three examinations—1. On anatomy and surgery; 2. On chemistry, materia medica, &c.; 3. On the essay he has written. If these are satisfactorily passed he is admitted to the fellowship. Fee £250; to apprentices of fellows, £100.

Course of Study — Preliminary Instruction.—Every candidate for the diploma of the royal college must, either previously to or during his medical education, have received regular instruction in the elements of mathematics, and must have subsequently attended a course of mechanical philosophy of at least three months' duration, and of not fewer than sixty lectures.

Professional Instruction.—The candidate must have been engaged in attending the following separate and distinct courses of lectures during a period of not less than twenty-seven months, in which must have been included three winter sessions of six months' duration each:—Anatomy, two courses of six months each; practical anatomy, twelve months; chemistry, one course of six months; practical chemistry (the number of pupils in each class being limited to twenty-five), one course of three months; materia medica and pharmacy, one course of six months; practical pharmacy,[1] one course of six months; institutions of medicine, or physiology, one course of six months; practice of medicine, one course of six months; clinical medicine, one course of six months, or two courses of three months each, during the period of his attendance at the hospital where they are delivered; principles and practice of surgery, two courses of six months each, or principles and practice of surgery, and military surgery,[2] one course of six months each; clinical surgery,[3] one course of six months, or two courses of three months each, during the period of his attendance at the hospital where they are delivered; midwifery, and diseases of women and children, one course of three months; medical jurisprudence, one course of three months.

The six months' courses delivered in Edinburgh must consist of not fewer than one hundred and ten lectures, with the exception of clinical medicine, clinical surgery, and military surgery. The three months' courses must consist of not fewer than sixty lectures. Two London courses of three months each on any of the above subjects will be taken as equivalent to one six months' course.

The candidate must also have attended for twenty-one months a public general hospital containing at least eighty beds. Students must register their cards of admission to the lectures, and also their certificates at the college; the registration fee is 5s.

Exemptions.—Candidates who have commenced attendance on their medical classes, or at a hospital containing at least eighty beds, or who have entered into indentures of apprenticeship to a regular surgeon, previously to the following dates, are entitled to the exemptions which are here specified:—

Date.	Exemptions.
Previously to 29th Sept. 1838.	1. From more than four winter sessions' attendance on a school of medicine.
Do.	2. From more than eighteen months of hospital attendance.
Do.	3. From more than six months of practical anatomy.
Do.	4. From the necessity of producing a certificate of age.
September 1833.	5. Also from practical pharmacy.
1st Aug. 1831.	6. Also from medical jurisprudence.

Examinations.—The days of examination are the first and third Tuesdays of every month. The fees must be lodged, before the examination, in the hands of the treasurer, who will certify this, after inspecting and being satisfied with the certificates. They will be returned to unsuccessful candidates, whose names will be concealed, and who will be remitted to their studies, for a period to be determined by the judgment of the examinators, but not, in any case, for less than three months. Every candidate, at the commencement of his examination, will be required to translate into English some portion of a Latin author; and if he be unable to do so, his examination cannot proceed. He is also expected to possess such a knowledge of drugs, and of the art of prescribing, as to be able to name particular substances that may be exhibited to him, and to write out formulæ for their administration. The president, if he judge it proper, may order a meeting for examination on any day at the request of a candidate; but in that case, the candidate must pay two guineas in addition to the customary fees; and this money will not be returned to him in the event of his being remitted.

Fees payable by Candidates.—For a diploma, ordinary candidates pay the sum of 7l 5s. Apprentices of fellows of the college, bound for the

[1] This is required of every candidate who does not produce a certificate of having been for the space of two years the private pupil or apprentice of a regularly licensed medical practitioner, keeping a laboratory for the dispensing of medicines. It must be attended at the laboratory of a surgeon or apothecary, or of a chemist and druggist recognised by the college on special application, or of a public hospital or dispensary, and the candidate must produce evidence that he has been engaged in compounding and dispensing medicines.

[2] The course of military surgery must be delivered by a professor of that branch in a university, or by a lecturer who, in addition to the other requisite qualifications, has served in the medical department of the army or navy, and the course must be of at least six months' duration, and comprehend not fewer than sixty lectures.

[3] Clinical medicine and clinical surgery must not be attended at the same time.

freedom, pay 1l 5s; other apprentices pay 2l 16s 6d. Assistant-surgeons in the navy, having previously obtained certificates from the college, pay 2l 11s 6d. Surgeons in the navy, having obtained certificates from the college, pay 15s 6d. For the certificate of qualification as assistant-surgeon in the navy, candidates not having paid for any previous qualification, 4l 19s 6d. For the certificate of qualification as full surgeon in the navy, assistant-surgeons who have already obtained certificates from the college, pay 3l 18s 6d, and those who have previously obtained the diploma of the college, pay 2l 17s 6d. These sums include fees of every kind.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

President, Dr. Perry.
Visitor, Dr. Weir.
Collector, Dr. James Wilford.
Seal-keeper, Dr. Pagan.
Librarian, Dr. Anderson.
Visitors of Drugs, Dr. McDowal, Mr. McGregor.
Assistant-Examinators, Drs. Laurie, Fleming, Douglas, Panton, Davidson, and Adams.

Regulations for the Surgical Diploma—Curriculum.—Anatomy, two courses of six months. Practical anatomy, one course of six months; enacted 7th June, 1830. Surgery, two courses of six months. Chemistry, one course of six months. Practical chemistry, one course of three months; enacted 8th November, 1831. Theory of medicine, one course of six months. Practice of medicine, one course of six months. Materia medica, one course of six months. Midwifery, one course of six months. Clinical medicine, one course of six months; enacted 7th June, 1830. Clinical surgery, one course of six months; enacted 7th June, 1830. Medical jurisprudence and police, one course of six months; enacted 4th April, 1831. Botany, one course of three months; enacted 3rd February, 1834. A public hospital, eighteen months; enacted 3rd February, 1834. A surgeon's or apothecary's shop, six months; enacted 3rd February, 1834. Every candidate must have been employed in the above course of studies for four winter sessions, or for three winter sessions and two summer sessions, so that the whole period of attendance shall not be less than three years complete. An essay, the subject to be fixed by the examinators, to be written by the candidate, in his own handwriting; and no essay to be submitted for a shorter period than twenty-four hours. Specimens of bones, or other anatomical or surgical preparations, or specimens from the materia medica, may be used at the discretion of the examinators. The diploma fee of seven guineas must be deposited with the president previous to the examination.

EXTRA-ACADEMICAL LECTURERS RECOGNISED BY THE COLLEGE OF SURGEONS, EDINBURGH.

Natural Philosophy—George Lees, A.M., School of Arts; Mr. George Glover, 6, Infirmary-street, £3 3s.

Anatomy and Physiology—Dr. Mercer, 4, Surgeons'-square; Drs. Handyside and Lonsdale, 1, Surgeons'-square; Dr. Skae, 11, Argyle-square; Mr. Hunter, 31, Nicolson-street, £3 3s.

Anatomical Demonstrations—Messrs. Mercer, Gunning, and Fowler, 4, Surgeons'-square; Dr. Handyside, Dr. Lonsdale, and Mr. Spence, 1, Surgeons'-square; Drs. Skae and Keiller, 11, Argyle-square; Messrs. Hunter, Clark, and Young, 31, Nicolson-street, 4l 4s, if taken conjointly.

Practical Anatomy—The above-named teachers of anatomy, 3l 5s.

Chemistry—Dr. Reid, Roxburgh-place, 3l 3s; Dr. Wilson, 24, Brown-square; Dr. Anderson, 3, Surgeons'-square, 3l 5s.

Practical Chemistry (three months' courses)—The above-named teachers of chemistry, 3l 5s.

Materia Medica and Dietetics—Dr. Seller, 11, Argyle-square; Dr. Douglas Maclagan, 9, Surgeons'-square, 3l 5s.

Institutes of Medicine—Dr. Howison, 8, Nicolson-square, 3l 5s.

Practice of Medicine—Dr. Craigie, 9, Surgeons'-square; Dr. Alexander Wood, 11, Argyle-square; Dr. Bennett, 1, Surgeons'-square, 3l 5s.

Clinical Medicine—Dr. Paterson, Royal Infirmary, 3l 5s.

Surgery—Drs. Argyll Robertson and Duncan, 11, Argyle-square, 3l 5s.

Clinical Surgery—Dr. Duncan, Royal Infirmary, 3l 5s.

Midwifery—Dr. W. Campbell, 11, Argyle-square; Dr. Marr (Midwife Dispensary), High School-yards, 3l 5s, perpetual.

Forensic Medicine—Dr. Cormack, Infirmary-street, 2l 5s.

All the courses are for six months, if not otherwise specified.

HOSPITALS AND DISPENSARIES IN EDINBURGH.

Royal Infirmary.—Medical and surgical practice, annual ticket, 5l 7s 6d; additional six months, 3l 5s 6d; ditto, three months, 1l 13s; perpetual, 12l 17s; certificate, 5s. Clinical lectures on medicine for six months, 3l 3s. On surgery for six months, 3l 3s. Dressers, six months, 3l 3s. Clinical clerks for three months, 3l 3s. Physicians' and surgeons' clerks, pay 52l 10s per annum, for board. The office is held for two years.

Surgical Hospital.—Surgical practice, three months, including clinical surgery, 3l 3; six months ditto, 5l 5s.

Maternity Hospital.—Six months, 1l 3s.

Lock Hospital.—Three months, 1l 1s.

Royal Dispensary.—First three months, 2l 2s; additional three months, 1l 1s. Clinical lectures, 2l 2s.

Newtown Dispensary.—Three months, 2l 4s; six months, 3l 5s. Instruction in pharmacy, one month, 1l 1s; three ditto, 2l 2s.

Minto-House Hospital and Dispensary.—Medical practice, three months, 2l 2s; six ditto, 3l 3s; perpetual, 6l 6s. Instructions in pharmacy, three months, 2l 2s; six ditto, 3l 3s.

Eye Infirmary.—Three months, 1l 1s.

Eye Dispensary.—Three months, 1l 1s.

MEDICAL SCHOOL, GLASGOW.

Anderson's University, George-street.—Surgery, chemistry, practical chemistry, midwifery, practice of physic, demonstrations and surgical anatomy, materia medica, descriptive and physiological anatomy, medical jurisprudence, institutes of medicine, each one course of six months, 2l 2s. Mechanical philosophy, six months' course, 1l 5s. Library fee, 2s 6d.

INFIRMARY IN GLASGOW.

Royal Infirmary.—Medical and surgical practice, two years, 7l 7s; perpetual, 8l 8s. Clinical clerks, eight months' fever wards, 5l; ditto, medical wards, 15l; ditto, surgical wards, 25l.

INFIRMARY, ABERDEEN.

Royal Infirmary.—Perpetual, 7l 7s. Clinical clerks, &c., no fee.

IRELAND.

UNIVERSITY OF DUBLIN. (TRINITY COLLEGE.) 1591.

Chancellor, His Majesty the King of Hanover.
Vice-Chancellor, his Grace the Lord Primate of Ireland.
Provost, Dr. Sadleir.

The days of graduation are, Shrove Tuesday, and the first Tuesday in July. The degree of bachelor of medicine may be obtained in two modes:—

1. Graduates in arts can obtain the degree at any of the half-yearly periods of graduation, provided the requisite medical education and examination shall have been accomplished. Fee for entrance, £15; fees for study in arts during four years, £7 10s each half year. Fees for graduation in arts, £8 17s 6d.

2. Candidates are admissible to the degree of M.B., without previous graduation in arts, at the end of five years from the July following the Hilary examination of the first undergraduate year, provided the usual education and examinations in arts of the first two years of the undergraduate course shall have been completed, as also the medical education and examinations, as in the case of other candidates. Fees for two years' study in arts (besides the usual entrance payment of £15) are £7 10s each half year. The graduation fees for the degree of bachelor of medicine are £11 15s. The medical education of a bachelor of medicine comprises attendance on the following courses of lectures in the School of Physic, provided that one, and not more than three, of the courses which begin in November be attended during each of four sessions. Three of these courses, at the discretion of the candidate, may be attended in the university of Edinburgh. The courses are on—anatomy and surgery; chemistry; botany; materia medica and pharmacy; institutes of medicine; practice of medicine; midwifery (by the professor to the college of physicians); clinical lectures at Sir Patrick Dun's hospital, during at least one session (six months), as delivered by the professors in the School of Physic; the attendance on such clinical lectures by the professors to be extended to three additional months of a summer session commencing in May. The examinations are conducted by the regius professor of physic of the university, the six professors of the School of Physic, and the professor of midwifery to the college of physicians. No further examination is requisite for the degree of doctor of medicine, which may be taken at the expiration of three years from having taken the degree of M.B., provided the candidate has graduated in arts. The fees for the degree of doctor of medicine are £22.

THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND. 1667—1692.

President, Dr. R. J. Graves.
Vice-President, Dr. George A. Kennedy.
Censors, Dr. George A. Kennedy, Dr. Hunt, Dr. Labatt, Dr Thomas Brady.
Treasurer, Dr. Collins.
Librarian, Dr. John O'Brien.
Registrar, Dr. Jonathan Labatt.

Professors (on the foundation of Sir Patrick Dun.)
Queen's Professors: Institutes of Medicine, Dr. Robert Law; Practice of Medicine, Dr. George Greene; Materia Medica and Pharmacy, Dr. Jonathan Osborne.
College of Physicians' Professors (elected by the College): Midwifery, Dr. William F. Montgomery; Medical Jurisprudence, Dr. Thomas Brady.

Qualifications of Candidates for Licence.—Candidates must produce evidence of having been engaged in the study of medicine for four years, and of having attended two at least of the required courses in each year. Candidates, except those who have taken a medical degree prior to 1840, must produce certificates of attendance on one or more courses of lectures on the following subjects, each course being of six months' duration, with the exception of botany and forensic medicine, which must include at least fifty lectures:—Anatomy and physiology, chemistry; materia medica and pharmacy, botany, institutes of medicine, practice of medicine, principles and practice of surgery, midwifery, and forensic medicine. Certificates must also be produced of six months' attendance on anatomical demonstrations and dissections, and of at least two years' hospital practice; one year in the hospital of the School of Physic in Dublin or Edinburgh, the other in any recognised medico-chirurgical hospital. The certificates must include attendance on the entire practice of the hospital, and on all the clinical lectures delivered in the hospital during such attendance. Candidates who have taken a medical degree in an university will be admitted to examination upon such degree alone. Every candidate for licence, except those who have taken a medical degree prior to 1840, is examined on two separate days: on the first day on anatomy and physiology, chemistry, botany, materia medica, and pharmacy; and on the second day on acute and chronic diseases, midwifery, and non-naturals, and on the translating of one or more of the following books from the original Greek—viz., Hippocrates, Aretæus, and Galen. Graduates in medicine are only required to undergo the second day's examination. The examinations, which are public, are conducted in the English language; but every candidate, except graduates in arts of Oxford, Cambridge, or Dublin, is required to translate medical cases from the English into the Latin language, before he is admitted to examination as to his professional acquirements. Fee for licence, £30.

ROYAL COLLEGE OF SURGEONS.

(1784—1828.)

President, Sir Philip Crampton, Bart.
Vice-President, Richard Carmichael, Esq.
Council: Samuel Wilmot, Alex. Read, Wm. Auchinleck, James W. Cusack, James Kerin, Arthur Jacob, Thomas Rumsley, W. Tagert, John Peebles, J. O. Beirne, John Hart, T. E. Beatty, W. Hargrave, Chas. Benson, Andrew Ellis, Robt. C. Williams, Francis White, Robt Harrison, Esqs.
Secretary, Dr. Cusack.
Registrar, C. O'Keeffe, Esq.

Bye-laws relative to Education and Examination of Candidates for Letters Testimonial and for the Fellowship.

Qualification for Letters Testimonial.—Every candidate must produce a receipt for 21*l*, paid into the Bank of Ireland on account of the college; and a certificate of his knowledge of Latin and Greek from the college examiners; certificates, showing that he has been engaged in the study of his profession for not less than four years, three of which shall have been passed in attendance on lectures or hospitals, in Dublin, London, Edinburgh, or Glasgow; certificates of attendance on a hospital recognised by the council, where clinical instruction is given, during three years; also on three courses on anatomy and physiology, three on surgery, and three courses of dissection, accompanied by demonstrations; two on chemistry, or one on general, and one on practical chemistry; one on materia medica; one on medicine; one on midwifery; and one on medical jurisprudence. Previous to the 1st June, 1845, candidates for letters testimonial, not educated in strict conformity with the foregoing regulations, may be admitted to examination, provided they can satisfy the council by documentary evidence, that they have gone through an equivalent course of study.

Qualifications for the Fellowship.—Every registered pupil or licentiate is admitted to examination for the fellowship on producing a receipt, showing that he has lodged in the Bank of Ireland, for the use of the college, the sum of ten guineas, in case he is a licentiate, or of twenty-five guineas, in case he is a registered pupil; provided, in either case, he intends to reside beyond ten miles from Dublin; otherwise, if he is a licentiate, twenty guineas, or if a registered pupil, thirty-five guineas. A certificate that he is twenty-five years of age. A certificate of a liberal preliminary education. A certificate signed by two or more fellows of the college, of good general conduct during his professional education. Certificates that he has been engaged in the acquisition of professional knowledge for a period of not less than six years; during three of which he must have studied in one or more of the schools and hospitals of Dublin. He may have studied for the other three years in any school or schools of the United Kingdom, which shall be approved by the council, or in any foreign school of repute. It is also required that the candidate shall have had opportunities of practical instruction as house-surgeon or dresser in a recognised hospital. Certificates of attendance on the several courses of lectures required to be attended by candidates for letters testimonial, together with one course of lectures on comparative anatomy, one on botany, and one on natural philosophy. A thesis on some medical subject; or clinical reports, with observations, of six or more medical or surgical cases taken by himself. Candidates of the required age, who shall have taken the degree of bachelor of arts in a British or Irish university, and have complied with the foregoing regulations in other respects, will be admitted to examination at the end of five years of professional study, of which three years must have been passed in one or more of the recognised schools or hospitals of Dublin. Licentiates of the college who may not be able to show that they have followed the course of study specified in the preceding regulations, may, at the expiration of ten years from the date of their diploma, be admitted to the examination required for the fellowship, provided they produce such evidence as shall be satisfactory to the council that they have conducted themselves honourably in the practice of their profession.

Qualifications for the Diploma in Midwifery.—Any fellow or licentiate of the college shall be admitted to an examination for the diploma in midwifery, on producing a certificate showing that he has attended one course of lectures on midwifery and diseases of women and children; a certificate, that he has attended the practice of a lying-in hospital for a period of six months; or, the practice of a dispensary for lying-in women and children; and a certificate that he has conducted thirty labour cases at least. Candidates for the midwifery diploma will be publicly examined on the organisation of the female; the growth and peculiarities of the fœtus; the practice of midwifery; and the diseases of women and children; and, if approved of, will receive a licence or diploma certifying the same.

APOTHECARIES' HALL OF IRELAND, 1791.

Court of Directors and Examiners.

Governor, T. Collins, Esq.
Examiners: Dr. Atkinson, Richard Barker, Esq., Dr. Betty, Ralph Mac Dermott, Esq., Dr. Leet, Dr. Mc Mann, Dr. Madden, sen., Dr. Madden, jun., James Mac Donough, Esq., Dr. Mullock, Dr. Moore, John Bellew, Esq., Dr. Holmes.
Secretary, Dr. Leet.

Candidates for the licence must produce the certificate of apprentice, and the indenture of apprenticeship, the latter bearing the certificate of his master that he is of good moral character, and has fulfilled the period of his apprenticeship, and certificates duly signed that he has diligently attended at least one course of lectures on each of the following subjects, delivered at the school of Apothecaries' Hall, or at some other school of medicine recognised by the court. Chemistry, anatomy, and physiology, six months; practical chemistry and botany, three months; materia medica, demonstrations and dissections, theory and practice of physic, surgery, midwifery, and the diseases of women and children, six months; medical jurisprudence, three months. A certificate of twelve months' attendance on the entire practice of a medico-chirurgical hospital, recognised by the court, containing not less than fifty beds, and where clinical instruction is regularly given, and a certificate of having assisted in at least thirty cases of midwifery, twenty of which must be attended in a recognised hospital. The examination for the licence to practise as an apothecary will be as follows:—In translating and explaining the processes of the British pharmacopœias and extemporaneous prescriptions; in chemistry and general physics; in materia medica and therapeutics; in natural history and medical botany; in anatomy and physiology; in the theory and practice of medicine; in midwifery; and in medical jurisprudence. Examinations on Friday, at two, p.m.

The examination for the licence to act as assistant to an apothecary in compounding and dispensing medicines will be confined to the following subjects:—To translate the Dublin pharmacopœia, and extemporaneous prescriptions; pharmacy, botany, materia medica, and mechanical philosophy.

The candidate for the assistant's licence may present himself for examination at the termination of five years' apprenticeship. Apprentices are examined as to their classical knowledge.

SCHOOLS OF MEDICINE IN DUBLIN.

School of Physic.—Medicine, 4*l* 4s. Materia medica, 4*l* 4s. Surgery, 2*l* 2s. Anatomy and physiology, 2*l* 2s. Demonstrations, 2*l* 2s. Practical anatomy, 2*l* 2s. Chemistry, 4*l* 4s. Midwifery, 4*l* 4s. Botany, 4*l* 4s. Forensic medicine 4*l* 4s.

School of Surgery.—Medicine, first course, 3*l* 3s; second ditto, 2*l* 2s. Materia medica, first course, 3*l* 3s; second ditto, 2*l* 2s. Surgery, first course, 3*l* 3s; second ditto, 2*l* 2s. Anatomy and physiology, first course, 3*l* 3s; second ditto, 2*l* 2s. Practical anatomy, 4*l* 4s. Chemistry, first course, 3*l* 3s; second ditto, 2*l* 2s. Practical chemistry, 2*l* 2s. Midwifery, first course, 3*l* 3s; second ditto, 2*l* 2s. Botany, 3*l* 3s. Forensic medicine, first course, 3*l* 3s; second ditto, 2*l* 2s. Natural philosophy, 2*l* 2s. Comparative anatomy, 1*l* 1s.

School of Medicine, Apothecaries' Hall.—Medicine, first course, 3*l* 3s; second ditto, 2*l* 2s. Materia medica, first course, 3*l* 3s; second ditto, 2*l* 2s. Surgery, first course, 3*l* 3s; second ditto, 2*l* 2s. Anatomy and physiology, first course, 3*l* 3s; second ditto, 2*l* 2s. Practical anatomy, 4*l* 4s. Chemistry, first course, 3*l* 3s; second ditto, 2*l* 2s. Practical chemistry, three months, 3*l* 3s; six ditto, 5*l* 5s (one guinea less with the general course). Midwifery, first course, 3*l* 3s; second ditto, 2*l* 2s. Botany, first course, 3*l* 3s; second ditto, 2*l* 2s. Forensic medicine, first course, 3*l* 3s; second ditto, 2*l* 2s.

School of Medicine, Park-street.—Medicine, first course, 3*l* 3s; second ditto, 2*l* 2s. Materia medica, first course, 3*l* 3s; second ditto, 2*l* 2s. Surgery, 2*l* 2s. Anatomy and physiology, 2*l* 2s. Demonstrations, 2*l* 2s. Chemistry, first course, 3*l* 3s; second ditto, 2*l* 2s. Midwifery, first course, 3*l* 3s; second ditto, 2*l* 2s. Forensic medicine, first course, 3*l* 3s; second ditto, 2*l* 2s.

Richmond Hospital School of Anatomy.—Medicine, first course, 3*l* 3s; second ditto, 2*l* 2s. Materia medica, first course, 3*l* 3s; second ditto, 2*l* 2s. Surgery, 2*l* 2s. Anatomy and physiology, 2*l* 2s. Demonstrations, 2*l* 2s. Chemistry, first course, 3*l* 3s; second ditto, 2*l* 2s. Midwifery, first course, 3*l* 3s; second ditto, 2*l* 2s. Botany, first course, 3*l* 3s; second ditto, 2*l* 2s. Forensic medicine, first course, 3*l* 3s; second ditto, 2*l* 2s.

Original School of Anatomy, Peter-street.—Medicine, first course, 3*l* 3s; second ditto, 2*l* 2s. Materia medica, first course, 3*l* 3s; second ditto, 2*l* 2s. Surgery, 2*l* 2s. Anatomy and physiology, 2*l* 2s. Demonstrations, 4*l* 4s. Midwifery, first course, 3*l* 3s; second ditto, 2*l* 2s. Forensic medicine, first course, 3*l* 3s; second ditto, 2*l* 2s.

HOSPITALS, &c., IN DUBLIN.

Sir P. Dun's Hospital.—Medical practice, 3*l* 3s annually.

Meath Hospital.—Fee 25*l*.

ECLIPSES IN 1846.

April 25, Sun.—An annular eclipse *visible* in Greenwich. Begins on the earth generally at 2h. 2·4m. p. m., mean time at Greenwich, in longitude 119° 40′ W. and latitude 6° 15′ S.; ends at 7h. 38·5m., in longitude 20° 4′ W., and latitude 20° 52′ N. Central eclipse begins generally at 3h. 3·3m. p. m. in longitude 135° 51′ W., and latitude 2° 11′ S.; ends generally at 6h. 37·6m. p. m., in longitude 3° 43′ W., and latitude 24° 56′ N. At Greenwich this eclipse is partial, beginning at 5h. 31·7m. p. m.; greatest phase at 6h. 13·8m.; ends at 6h. 54m. Magnitude of the eclipse (sun's diameter = 1), 0·277, on the southern limb.

October 20, Sun.—An annular eclipse, *invisible* at Greenwich. Begins on the earth generally at 4h. 46·7m. a.m., mean time at Greenwich, in longitude 16° 21′ E. and latitude 9° 50′ N.; ends at 10h. 44·1m. in longitude 109° 6′ E. and latitude 20° 47′ S. Central eclipse begins generally at 5h. 52m. a. m., in longitude 0° 32′ W. and latitude 6° 44′ N.; ends generally at 9h. 38·9m., in longitude 126° 5′ E. and latitude 23° 51′ S.

THE FOUR QUARTERS OF THE YEAR.

Spring Quarter begins	March	20	11h 46m	afternoon.
Summer "	June	21	8 32	afternoon.
Autumnal "	Sept.	23	10 30	morning.
Winter "	Dec.	22	4 12	morning.

TERMS AND RETURNS.

Hilary Term begins Jan. 11—Ends Jan. 31.
Easter Term begins April 15—Ends May 8.
Trinity Term begins May 22—Ends June 12.
Michaelmas Term begins Nov. 2—Ends Nov. 25.

The first General Return Day for every term is the fourth day before the first day of the term, both days being reckoned in the computation. In Hilary Term, therefore, the first General Return Day will be January 8; Easter Term, April 12; Trinity Term, May 19; and Michaelmas Term, Oct. 30. There were also three other General Return Days in the term upon which certain writs were returnable; but now, by the statute 1 Wm. IV., cap. 3, sec. 2, "all writs now usually returnable before any of his Majesty's Courts of King's Bench, Common Pleas, or Exchequer, respectively, on General Return Days, that shall be made *returnable* after the 1st of January, 1831, may be made returnable on the third day exclusive before the commencement of each term, or on any day (not being Sunday) between that day and the third day exclusive before the last day of the term; and the day for appearance shall, as heretofore, be the third day after such return, exclusive of the day of return; or, in case such third day shall fall on a Sunday, then on the fourth day after such return, exclusive of such day of return." When the terms themselves commence on a Sunday, the term is dated from such day, although the sittings do not commence till the following day. In the calendar the duration of the term is marked by a strong line.

OXFORD TERMS.

	Begins.	Ends.
Lent Term	Jan. 14	April 4
Easter Term	Apr. 22	May 30
Trinity Term	June 3	July 11
Michaelmas Term	Oct. 10	Dec. 17

The Act will be July 7.

CAMBRIDGE TERMS.

	Begins.	Divides.	Ends.
Lent	Jan. 13	Feb. 22, n.	Apr. 3
Easter	Apr. 22	May 31, m	July 10
Michaelmas	Oct. 10	Nov. 12, m	Dec. 16

The commencement will be July 7.

TERMS IN ENGLAND.

Usually taken in Leases.

25 March ......Lady Day	29 Sept ......Mich. Day
24 June ......Midsum.	25 Dec. ......Christmas

IN SCOTLAND.

Candlemas........Feb. 2	Lammas ....Aug. 1
Whitsund.* ......May 15	Martinmas ......Nov. 11

* This term, in Scotch leases, does not depend upon the moveable feast of Whitsuntide, but is permanent.

TRANSFER DAYS.

The transfer days are now Tuesdays, Wednesdays, Thursdays, and Fridays. Dividends are due at the following dates, and are receivable at any time subsequently.

AT THE BANK.

Bank Stock	April 5, Oct. 10
3 per Cent. Cons. / 3 per Cent. 1726	Jan. 5, July 5
3 per Cent. Reduced	April 5, Oct. 10
New 3½ per Cent. Annuities / New 5 per Cent. Annuities	April 5, Oct. 10
3½ per Cent. Reduced / 3½ per Cent. 1818	April 5, Oct. 10
Con. Long Annuities	April 5, Oct. 10
Annuities for Terms of Years, ending 10th Oct. 1859, pursuant to 10th George IV	April 5, Oct. 10
Annuities for Terms of Years, ending 5th Jan. 1860, pursuant to 10th Geo. IV.	Jan. 5, July 5
Life Annuities, if purchased between Jan. 5, and April 4, or between July 5 and Oct. 9	Jan. 5, July 5
If purchased between April 5 and July 4, or between Oct. 10 and Jan. 4	April 5, Oct. 10

AT THE SOUTH SEA HOUSE.

South Sea Stock / New 3 per Cent. Annuities	Jan. 5, July 5
Old 3 per Cent. Annuities	April 5, Oct. 10
3 per Cent. 1751	Jan. 5, July 5

AT THE EAST INDIA HOUSE.

Stock	Jan. 5, July 5
Interest on India Bonds, due..	Mar. 31, Sep. 30

Tickets for preparing transfer of stock must be given in at each Office before 1 o'clock.—At the East India House before 2.

Private transfers may be made at other times than as above, the Books not being shut, by paying at the Bank, India House, and South Sea House 2s 6d extra for each transfer; but no transfer can be made after 1 o'clock on Saturdays.

Transfer at the Bank must be made by half-past 2 o'clock; at India House by 3; at South Sea House by 2.

Expense of Transfer in

Bk. Stock, £25 and under, 9s; above that sum, 12s
Ind. do. £10 " £1 10s; " £1 10s
S. Sea do. if under £100 9s 6d; " 12s

Powers of attorney for the sale or transfer of stock must be deposited at the Bank, &c., for examination, one day before they can be acted upon; if for receiving dividends, it is sufficient to present them at the time the first divdend becomes payable.

The expense of a power of attorney is £1 1s 6d for each stock separately, but for Bank, India, and South Sea Stock, £1 11s 6d; and when required to be made out on the same day, half-past twelve o'clock is the latest time for receiving orders. The boxes for receiving powers of attorney for sale close at two o'clock.

All probates of wills, letters of administration, and other proof of decease, are required to be left at the Bank, &c., for registration from two to three clear days, exclusive of holidays.

HOLIDAYS KEPT AT THE PUBLIC OFFICES IN 1846.

By an Act of Parliament passed in 1834, much of the money business of the Exchequer is removed to the Bank of England. At the Exchequer all holidays are abolished except Christmas Day and Good Friday.

CUSTOM-HOUSE, EXCISE, STAMPS AND TAXES OFFICES.

Good Friday, April 10. Queen's Birth-day, May 24. Prince of Wales's Birth-day, Nov. 9. Christmas, Day Dec. 25.

All the above days are also ordered to be kept as holidays by the officers and servants of the Dock Companies of the United Kingdom. At the Stamps and Taxes Office, the Restoration of Charles II., May 29; Whit Monday and Tuesday, are kept in addition.

INDIA HOUSE.

Good Friday, April 10 | Christmas Day, Dec. 25

BANK OF ENGLAND.

Good Friday, April 10 | Christmas Day, Dec. 25

And, in the Transfer Offices, 1st May and 1st November in addition.

N.B.—Whenever the 1st May or 1st November falls on a Sunday the holiday will be kept on the Monday following.

SOUTH SEA HOUSE.—Same as Bank of England.

AGREEMENT.

Of the value of £20 and upwards, containing only 1080 words, £1; more than 1080 words, £1 15s; and for every further 1080 words, £1 5s.

DUTIES ON LEGACIES,

Of the Value of £20 or upwards, out of Personal Estate, or charged upon Real Estate, &c.; and upon every share of Residue :—

To a child or parent, or any lineal descendant or ancestor of the deceased, £1 per cent.—To a brother or sister, or their descendants, £3 per cent.—To an uncle or aunt, or their descendants, £5 per cent. —To a great uncle or great aunt, or their descendants £6 per cent. To any other relation, or any stranger in blood, £10 per cent.—Legacy to husband or wife exempt.

If the deceased died prior to the 5th April 1805, the duty only attaches on Personal Estates, and by a lower scale.

SPOILED STAMPS.

The days for claiming the allowance at Somerset-house are Tuesdays, Thursdays, and Saturdays, from 12 to 2 o'clock. If parties reside within ten miles of London, application must be made within six calendar months from the time the stamps became spoiled, when not executed upon instruments; and when upon such instruments, within six months from their date. If parties reside beyond the said limit of ten miles, the application must also be made within six months from the date, when the stamps are upon executed instruments; but in all other cases, within twelve months from the date of the stamps becoming spoiled. The affidavit in support of the application, when not made before a Commissioner at Somerset-house, or a Distributor of Stamps in the country, when such Distributor is authorised to administer the same, must be upon a stamp of 2s 6d, and made before a Master Extraordinary in Chancery.

ASSESSED TAXES.

DUTIES ON MALE SERVANTS.

No.	At per Servant. £	s.	d.	Bachelor's ditto. £	s.	d.

If not so assessed	3	13	6
On every other person using dog, gun, net, or engine, for the taking or killing of game	3	13	6

In case of any person omitting to take out the proper certificate, the surveyor of taxes will bring him into charge, and the assessment must be double in every case.

By 1 and 2 Will. IV., cap. 32, persons licensed to deal in game are to take out a certificate, charged with a duty of £2; but certificated persons may sell game to licensed dealers, if paying a duty of £3 13s 6d.

Note.—By the 3rd Vic., c. 17, sec. 8, an additional duty of 10 per cent. is imposed on all assessments made after the 6th April, 1840, except on carriages let to hire with horses, and chargeable to the duty of £3.

STAGE-COACH DUTIES.

These duties are collected under 2 and 3 Will. IV., c. 120, 3 and 4 Will. IV., c. 48, and 5 and 6 Vict., c. 79.

By the above acts, every stage-carriage is required to be licensed, either at the Stamp Office, or by a distributor of stamps, before it is used.

For every original license £3 3s.

For every supplementary license 5s.

Every stage-carriage is also chargeable with a mileage duty of 1½d.

Duties on Passengers conveyed for hire by Carriages travelling upon Railways.

£5 per cent. on the gross amount of fares.

HACKNEY-CARRIAGE FARES.

All vehicles, whether on two or more wheels, plying for passengers in any part of the metropolis, within five miles of the General Post Office, with the exception of those licensed as stage-coaches, are deemed hackney-carriages within the provisions of the act.

Fares according to Distance.—For every hackney-carriage drawn by two horses any distance not exceeding one mile, one shilling, and sixpence for every additional half-mile, or fractional part of half a mile.

Fares according to Time.—For every hackney-carriage drawn by two horses any time not exceeding half an hour, one shilling, and sixpence for every additional quarter of an hour, or fractional part thereof.

CABRIOLETS.

For every hackney-carriage drawn by one horse only, two-thirds of the rates and fares above-mentioned.

Persons using armorial bearings, and keeping a coach, or other taxable carriage, £2 8s. Persons not keeping such carriage, but charged to the window duty, £1 4s. Persons not keeping such carriage, nor being chargeable to the window duty, 12s.

THE ROYAL FAMILY OF GREAT BRITAIN AND IRELAND.

QUEEN VICTORIA, born May 24, 1819; succeeded June 20, 1837; married, February 10, 1840, to Albert Francis Augustus Charles Emanuel, Duke of Saxe Coburg and Gotha, born August 26, 1819. Temperance Provident—39, Moorgate-street.
Widows' National and General—3, Adelaide place, London-bridge.

* In these the mutual assurers also assure other parties who do not participate in the profits.

GENERAL POST OFFICE, LONDON.

EVENING MAILS.

The Receiving Houses are open for general post letters till half past five, and at St. Martin's-le-Grand and the Branch Offices at Charing-cross, Old Cavendish street, Blackman-street, Southwark, and Lombard-street, till six, without fee; at the three first Branch Offices till a quarter to seven; and at Lombard-street and the General Post Office, St. Martin's-le Grand, till seven, paying 1d each; the extra penny on all inland letters to be paid by a stamp, but upon foreign, colonial, or ship letters the penny must be paid in money.

General post letters are charged by weight, as follows:—

Letters not exceeding ½ oz., one postage
Do. 1 oz., two postages
Do. 2 oz., four postages
Do. 3 oz., six postages

and so on, adding two postages for every ounce up to 16 ounces, beyond which no packet subject to postage will be received; but parliamentary papers are an exception. The price of a postage is one penny, which must be prepaid, either by money or the use of a stamp, or it will be charged double, and if the weight of the letter should exceed the value of the stamps attached, the excess will be charged double: thus, a letter weighing more than half an ounce, but not exceeding an ounce, if bearing one penny stamp only, will be charged an additional twopence on delivery. Stamped envelopes are to be purchased at every post office, as well as at most stationers, at the rate of 1s 1½d per doz. of penny and 2s 2d per doz. of two-penny envelopes, and this rate is most rigidly ordered to be observed in all fractional parts of the dozen.

Newspapers, to go the same day, must be put into the General Post Office before six o'clock; but those put in before half-past seven o'clock will go the same evening by paying a halfpenny with each. In the branch offices they must be put in before five. They must be sent in covers, open at the sides, and no words or communication must be printed on such paper after the same shall have been published, nor any writing or marks upon such printed paper, or the cover thereof, other than the name and address of the person to whom it is sent. If addressed to persons who have removed, they may be re-directed, and sent free of extra charge. Such papers may be examined by the Post Office officers; and, if there be any breach of the above regulations, the packet shall be charged with treble letter postage; and, if it shall appear not to have been duly stamped, shall be stopped and sent to the Commissioners of Stamps.

British newspapers sent to foreign countries (where they are permitted to go free through the foreign post) go free: but if otherwise, they are charged a British postage of 2d each, or a rate equivalent to the foreign rate. French newspapers are subject to a postage in England of one halfpenny. English papers pay in France a postage of 5 centimes.

Newspapers to and from the Colonies are transmitted free (unless sent by private ships), and must be posted within a week of their publication.

MORNING MAILS.

The following is a list of the morning mails which leave the General Post office, London:—List of post towns to which letters and newspapers are transmitted by the morning mails, viz., Abingdon, Accrington, Alnwick, Andover-road, Appleby, Ashford, Attleborough, Banbury, Bangor, Bath, Barnsley, Basingstoke, Battle, Beaumaris, Belford, Belper, Berwick, Berkhampstead, Bilston, Birmingham, Bishop's Stortford, Blackburn, Bolton, Bradford (Yorkshire), Brackley, Brandon, Bridgwater, Brentwood, Bristol, Brough, Buckingham, Burnley, Bury (Suffolk), Cambridge, Canterbury, Carlisle, Carnarvon, Chatham, Chepstow, Cheltenham, Chester, Chesterfield, Chippenham, Chelmsford, Chester-le-street, Cirencester, Clitheroe, Cockermouth, Chorley, Colchester, Conway, Coventry, Cowes, Cranbrook, Cuckfield, Darlington, Dartford, Daventry, Derby, Dorking, Dover, Dunmow, Dursley, Durham, Ely, Exeter, Farnham, Fairford, Farringdon, Felton, Fenny Stratford, Feversham, Folkstone, Gateshead, Godalming, Gloucester, Gosport, Grantham, Gravesend, Guildford, Guernsey, Halifax, Hastings, Hemel Hempstead, Hertford, Highworth, Hoddesdon, Holyhead, Holywell, Huddersfield, Hurst Green, Hythe, Jersey, Ipswich, Kendal, Kelvedon, Kenilworth, Lancaster, Leeds, Leamington, Leicester, Lechlade, Leighton Buzzard, Lewes, Liverpool, Loughborough, Maidenhead, Maidstone, Manchester, Margate, Maryport, Melton Mowbray, Milnethorpe, Mold, Monmouth, Morpeth, Newcastle (Stafford), Newcastle-on-Tyne, Newmarket, Newport (I. W.), Newport Pagnel, North Shields, Northampton, Nottingham, Norwich, Oxford, Penkridge, Penrith, Portsmouth, Preston, Preston Brook, Pwllheli, Ramsgate, Reading, Reigate, Rickmansworth, Rochdale, Rochester, Rotherham, Rugby, Ryde, Saffron Walden, Sevenoaks, Sheffield, Shiffnall, Sittingbourne, Shoreham, Shrewsbury, Slough, Sunderland, South Shields, Southampton, Staplehurst, St. Asaph, St. Alban's, St. Leonard's, Stafford, Stockport, Stone, Stroud, Stony Stratford, Stratford-on-Avon, Swinton, Tenterden, Taunton, Thirsk, Tetbury, Thetford, Towcester, Tring, Tunbridge, Tunbridge Wells, Ulverston, Uxbridge, Wakefield, Wallingford, Walsall, Ware, Warrington, Warwick, Watford, Wednesbury, Weedon, West Bromwich, Wellington (Salop), Wellington (Somerset), Whitehaven, Wigan, Witham, Wigton, Winchester, Windsor, Wolverhampton, Workington, Worthing, Wootton-under-Edge, Wymondham, Yarmouth, York, and all Ireland and Scotland. For all the above places the letter boxes at the receiving house will be open until seven o'clock, a. m., for newspapers, and eight o'clock for letters; and at the branch offices Charing-cross, Cavendish-street, and the Borough, until half-past seven for newspapers, and eight o'clock, a. m., for letters; and at the General Post-office and branch in Lombard-street, until a quarter to eight for newspapers, and half-past eight, a. m., for letters.

No person will be permitted hereafter to send or receive letters free of postage. Members however of either House of Parliament will be entitled to receive, free of charge, petitions addressed to either House of Parliament, provided they are sent without covers, or in covers open at the sides, and do not exceed the weight of thirty-two ounces. Addresses to her Majesty will likewise go free of postage.

The rates on newspapers and letters of soldiers and sailors will remain unaltered, with the exception, however, that the privilege now given to soldiers' and sailors' letters will be restricted to the cases in which they shall not exceed half an ounce in weight.

Letters and packets exceeding sixteen ounces in weight, with the exception of those classes mentioned below, cannot be forwarded to their destination, but will be sent to the Dead Letter Office.

The following are the exceptions to this rule:—Parliamentary Petitions and Addresses to Her Majesty, Parliamentary proceedings, letters and packets addressed to or received from places beyond sea, letters and packets to and from Public Departments, and to and from Public Officers; Deeds, if transmitted under such regulations as the Postmaster-General may consider necessary. The rate of postage for Parliamentary Papers is one penny for every four ounces.

Letters containing coin or articles of value are recommended to be registered. Such letters and any others may be registered at any of the receiving-houses in London till five o'clock, for the evening mail, and at any post-office in the country until within half an hour of the closing of the bag to the place for which they are directed. The registration only extends, if a foreign letter, to the port of despatch, except to France. The fee in any case in Great Britain is a shilling and the postage, and to France a shilling and double the French postage. Such letters bearing a sufficient number of stamps will pass as paid letters, but the registration fee must in every case be paid in money.

Money orders for sums under £5 are granted by every post-town upon every other post-town in the United Kingdom, on application at the various offices; and also by and upon certain offices in the metropolis, of which the postmasters are furnished with a list, for which a commission of 3d for £2, and 6d for any sum above £2 and not exceeding £5, is charged. Post Office Orders are recommended for small sums; and, if neither that nor registration be adopted, that all bills, notes, &c., be cut in halves, and sent by different posts; the numbers, dates, &c., should also be carefully taken.

SUPPLY OF MEDICINES IN THE MERCANTILE SHIPPING.

The Lords Commissioners of Her Majesty's Treasury having had under their consideration a representation of the Commissioners of the Customs, relative to the evasion of the clause in the Merchant Seamen's Act, requiring merchant vessels to take on board and have in store certain quantities and descriptions of medicines, and their Lordships have communicated to the Lords Commissioners of the Admiralty on the subject, have approved of the suggestion of the Board, that vessels required to carry medicines by the act 7 and 8 Victoria, chap. 112, are to be occasionally boarded or visited by the revenue officers for the purpose of ascertaining the quantities of medicines, &c., shipped for the use of the crew; and directions have been issued to the principal officers of the revenue at the several ports of the United Kingdom, and other places traded to by British vessels, to take care that their Lordships' orders are duly carried into effect from the present time. The 18th section of the act alluded to directs that every ship navigating between the United Kingdom, and any place out the same, shall have and keep constantly on board a sufficient supply of medicines and medicaments suitable to accidents and diseases arising on sea voyages, in accordance with the scale which shall, from time to time, or at any time, be issued by the Admiralty; and every ship (except those bound to European ports, or to ports in the Mediterranean Sea) is also to have on board a sufficient quantity of lime or lemon-juice, sugar, and vinegar, the same being served out to the crew whenever they shall have been consuming salt provisions for ten days: the lime or lemon-juice and sugar daily, after the rate of half an ounce each per day, and the vinegar weekly, at the rate of half-a-pint per week to each person, so long as the consumption of salt provisions is continued; and in case of default in keeping the articles mentioned in store, the owner of the vessel incurs a penalty in each instance of £20; and in default of serving them out as stated, a penalty in each instance of £5; and in case the master or any seaman receives any hurt or injury in the service of the ship, the expense of providing the necessary surgical and medical advice, with attendance and medicines, and for his subsistence until cured or brought back to some port of the United Kingdom, is, together with the costs of his conveyance home, to be defrayed by the owner of the ship, without any deduction whatever on that account from the wages of the master or seaman.

To make this regulation more valuable, no vessel should be allowed to leave England for a longer voyage than within the four seas, without carrying an experienced surgeon. It is but of little use providing the tools, unless the master be there to use them.

PATENT MEDICINE LICENCES.

If a general practitioner, chemist and druggist, or other person, sell patent or proprietary medicines without having a licence, he is liable to a fine of £20; if there be not also a stamp so affixed to the article that it cannot readily be removed, he will forfeit £10. The licence will cost £2, if the medicines are sold within the cities of London and Westminster, the borough of Southwark, and the limits of the Two-penny Post; £1 in any other city, 10s in a borough, and 5s for towns and villages.

TO SUBSCRIBERS OF THE MEDICAL TIMES.

The ALMANACK is this year published as a substitute, not as an accompaniment, of the ordinary number. The next number will be paged from that of last week.
